

THE
INDIAN MEDICAL RECORD,

A WEEKLY JOURNAL OF THE

Allied Sciences of Medicine, Surgery, Obstetrics and Sanitation,

with which is incorporated a complete

Government Medical Gazette for the Indian Empire.

EDITED BY

JAMES ROBERT WALLACE, M. D., F. R. C. S. I.,

L. R. C. P. & S., Edin., L.M., L. S. A., Lond.,

F. O. S., Lond.

Member, British Medical Association, &c.

VOL. XX.

JANUARY TO JUNE.

1901.

LIST OF CONTRIBUTORS TO THE INDIAN MEDICAL RECORD.

FOR VOLUME XX.

JANUARY TO JUNE 1901.

(I.M.S.) Indian Medical Service; (R.A.M.C.) Royal Army Medical Corps; (C.) Civil Medical Service;
(I.) Independent; (M.) Military Assistant Surgeon.

Adami, J. G., M.A., M.D.	I.	Lal, Munni, L.M.S.	C.
Andrews, Arthur, M.R.C.S., L.S.A., Lond.	I.	Laurie, Henry, M.B., B.S.	I.
Angus, H. Brunton, M.B., M.S.	I.	Leonard, Charles Lester, A.M., M.D.	I.
Apte, Y. G., B.A., L.M.S.	C.	Lockwood, C. B., F.R.C.S.	I.
Aquino, T. H., Assistant Surgeon, L.M.S.	C.	Lewtas, J., Lieut.-Col., M.D., Lond.	I.M.S.
Arnott, James, M.D.	I.	Little, Seelye, W., M.D.	I.
Atkinson, T. Renell, M.D.	I.	Lord, C. Courteney, M.A., M.R.C.S.	I.
Avari, Cooverji Rustomji, C.M.S.	C.	Lyons, Major, M.D.	I.M.S.
Babonau, R. G., Assistant Surgeon.	M.	Macilwain, S. U., L.R.C.P., Lond., M.R.C.S., Eng.	I.
Baldwin, J. F., A.M., M.D.	I.	MacLaurie, Chas., M.B., C.M.	I.
Balfour, G. W., M.D., LL.D.	I.	Marin, Thos. Chas., M.D.	I.
Balm Edward, G.H.M.S.	C.	Martin, R. Humphrey, M.B., B.S., M.R.C.S.	I.
Bardswell, Noel Dean, M.D., M.R.C.P., Edin. & Lond.	I.	McDonagh, John W., M.D., M.R.C.P.	I.
Basu, Beni Madhub, L.C.M.S.	I.	McGuire Stewart, M.D.	I.
Beatson, Geo. Thos., M.D.	I.	McFarlane, W. M., M.B.	I.
Beeston, Joseph L., L.R.C.P.I., L.R.C.S.I.	I.	Masina, H. M., L.M.S., L.R.C.S.	I.
Blumer, Percy W., F.R.C.S., Edin.	I.	Mitra, A., Rai Bahadur, L.R.C.P. and S., Edin.	I.
Bonnar, Thos. H., Assistant Surgeon.	M.	Modlio, I. J., M.D., B.S.	I.
Bonnar, Miss. K., L.M.S.	C.	Monks, Chas., Lieut.-Col.,	I.M.S.
Bose, Kailas Chundra, Rai Bahadur, L.M.S., C.I.E.	I.	Moore, R. R. H., Major, M.D.	R.A.M.C.
Bovee, J. Wesley, M.D.	I.	Montizambert, M.D., F.R.C.S., D.O.L.	I.
Brothers, Abram, M.S., M.D.	I.	Morrow, Jos. E., M.D.	I.
Bulkley, Duncan, A.M., M.D.	I.	Mukerjee, Atul Chundra, C.M.S.	C.
Buchanan, W. J., Major, M.D., D.P.H.	I.M.S.	Nair, M. N. Govindan, C.M.S.	C.
Butler, Glentworth R., M.D.	I.	Nash, Gifford W., F.R.C.S.	I.
Cahot, Follen, M.D.	I.	Naylor, A. G. E., L.R.C.P. and L.R.C.S., Edin.	I.
Campbell, Colin, L.R.C.P.I., M.R.C.S.	I.	Niles, H. R., M.D.	I.
Charles R. Havelock, Major, M.D., M. CH., F.R.C.S.I.	I.M.S.	O'Connell, Mathew D., M.D.	R.A.M.C.
Chester, W. T., Lieutenant-Col., M.B.	R.A.M.C.	Ohlelar, M. M., Rai Bahadur, L.M.S.	C.
Chesne, John, F.R.C.S., Edin.	I.	Paparrow, C.	C.
Choksy, N. H., Khan Bahadur, M.D.	C.	Parkinson, J. T., Assistant Surgeon.	M.
Crittenden, William J., M.D.	I.	Perry, F. F., Lieut.-Col.	I.M.S.
Cuscaden, George, L.R.C.P. & S., Edin.	I.	Pestonjee, Dabiboy P., G.H.M.S.	C.
Darnell, William Edgar, A.B., M.D.	I.	Pinn, Joshua, F.R.C.S.I.	I.
Delepine, Shiredan, M.D.	I.	Rajiah, Yelliah R., G.H.M.S.	C.
Dreunan, Jennie G., M.D.	I.	Reckless, Alfred, M.R.C.S.	I.
Eustace, Henry M., M.D.	I.	Rees, David C., M.R.C.S., L.R.C.P.	I.
Flick, Lawrence, M.D.	I.	Register, C., M.D.	I.
Flint, Austin, Jr., M.D.	I.	Robertson, J. W., M.D.	I.
Foreman, J., M.R.C.S.	I.	Savary, Horace, M.A., M.B.	I.
Fox, Hingston R., M.D., M.R.C.P., Lond.	I.	Savidge, Eugene Coleman, M.D.	I.
Gardiner, W. A., Colonel, L.R.C.P.I.	R.A.M.C.	Seandner, A., M.D., M.R.C.S., Eng., L.R.C.P., Lond.	I.
Gibson, J. Lockhart, M.D., Edin., M.R.C.S., Eng.	I.	Scharlieb, Mary Ann DaComb, M.D., M.S., Lond.	I.
Gillam, J. B., M.B.M.C.	I.	Shah, T. M., L.M.S.	C.
Gillmon, J. C., L.S.A., Lond.	M.	Sheridan, J. P., M.D.	I.
Grant, Dundas J., M.D., Edin., F.R.C.S.	I.	Skevington, J. O., F.R.C.S.	I.
Groves, H. J. F., M.R.C.S., L.R.C.P.	I.	Sircar, Bhootan Mohan, L.M.S.	C.
Hammond, William, M.R.C.S.	I.	Smyth, John, Major.	I.M.S.
Handford, Henry, M.D., F.R.C.P.	I.	Smyth, Butler A. C., F.R.C.S., Edin.	I.
Harris, L. Herschel, M.B., CH.M.	I.	Sontham, F.A., M.B., F.R.C.S.	I.
Harvey, L. Watson, L.R.C.P. & L.R.C.S., L.F.P.S.	I.	Stewart Balfour, M.A., M.B.	I.
Hayes, E. C., Captain.	R.A.M.C.	Taylor, H. T., Lechnere, M.B., C.M.	I.
Hazen, W. P. C., M.D.	I.	Tennant, John, M.A., M.B., Edin.	I.
Heath, Christopher, F.R.C.S.	I.	Thompson, C. M., Lieut.-Col., M.B., B.C.U.	I.M.S.
Hinder, H. V. Critchley, M.B., CH.M.	I.	Torpy, A. N.	I.
Holt, E. E., M.D.	I.	Vaghan, Victor C., M.D.	I.
Horwitz, Orville, B.S., M.D.	I.	Wallace, James R., M.D., F.R.C.P.I.	I.
Jardine, Robert, M.D.	I.	Ward, Geo. Gray, Jr., M.D.	I.
Jilani, Ghulam, M.H., C.M.S.	C.	Whitehead, H. R., Lieut.-Col., F.R.C.S.	R.A.M.C.
Jones, M. Handfield, M.D., L.R.C.P.	I.	White, Chas. Powell, M.B., F.R.C.S.	I.
Kahler, J. Frank, M.D.	I.	White, Ada, Miss, L.M.S.	C.
Kelly, Howard, M.D.	I.	Wilson, Thomas, M.D., F.R.C.S.	I.
Kuagge, Samuel T., M.D.	I.	Wyat, Maokie, M.D.	I.
Kobler, Dr. G.	I.	Williams, J. T., M.R.C.S.	I.
Krause, Frederick, M.D.	I.	Williams, Whitridge J., M.D.	I.

INDEX

TO THE

INDIAN MEDICAL RECORD.

VOL. XX.

JANUARY TO JUNE 1901.

A

- Abdominal aorta.** Ligation of the, 147.
Abdominal hysterectomy. 425.
Abnormal heat in Calcutta. 667.
Abortion case. Indictment and dying declaration in, 321.
Abortion. Criminal frequency of, among the married, 118.
Abortion. Note on the occurrence of, 616.
Abortion remnants. Hand and finger in, 453.
Abortion. To prevent, 297.
Abortion. Treatment of, 148—268.
Abscess and gangrene of the lung, 590.
Abscess. Sub-hepatic, 65.
Accessory nasal sinuses. Anatomy of the, 20.
Acetonuria, 121.
Acromegaly. Case of, 589.
Action of morphine in the stomach, 374.
Action of quinine in pregnancy, 151.
Actinomycosis, 424.
Acute alcoholism. For, 402.
Acute articular rheumatism, 396.
Acute cystitis, 616.
Acute dilatation of the heart in diphtheria, influenza and rheumatic fever, 292.
Acute hæmorrhagic pancreatitis. Two cases of, 204.
Acute intestinal obstruction. The treatment of, the practitioner's duty in, 14.
Acute mania. Bromide sleep in the treatment of, 203.
Acute senile endometritis, 372.
Acute yellow atrophy of the liver. Pathogenesis of, 73.
Adenoids and ear disease. Nasopharyngeal, 396.
Adenoids. Pathology of, 480.
Adolescence. Treatment of the permanent teeth during, 590.
Advertising by dentists, 368.
Affections of the eye. Ichthyol in, 669.
Affections noted in smokers, 568.
Agglutinating power of human blood serum, 177.
Ague pills. Hamlet's, 672.
Aid in diagnosis. Inhibition of the heart as an, 423.
Albert Victor Asylum, 588.
Albert Victor Hospital, Calcutta, 500.
Albuminuria. Diet in, 22.
Albuminuria in young women, 17.
Albumin. Heller's test of urine for, 293.
Alcohol. Pathology of, 46.
Alcohol. Effects of, recent views on the, 427.
Alcohol. Influence of, upon the liver, 504.
Alcohol. Value of, in the acute infectious diseases of children, 649.
Alcoholic neuritis. Face and pupil in, 477.
Alkalinity of the blood and the bactericidal power in leucocytosis from intoxication by mineral poisons, 295.
Almora as a health resort for consumptives, 643.
Alopecia. Pathology of, 618.
Amblyopia. Post-marital, 121.
Ambulance corps. Return of a disgraced, 41.
Amenorrhœa in debilitated and anæmic states, 375.
Amenorrhœa. For, 348.
American cigarette. The, 534.
American tribute to the passing of a gracious Sovereign, 290.
Amputation of the leg by cocainising the spinal cord, 97.
Amylen hydrate in diabetes insipidus, 48.
Animals. Acid resisting bacilli in the lower, 124.
Antiflexion, 19.
Antiseptic properties of glycerine, 151.
Anæmia. Causes and treatment of, 584.
Anæmia with enlargement of the spleen, 397.
Anæsthesia (Corning-Bier method). Injection of cocaine for present status of subarachnoidean, 560.
Anæsthesia. Teaching of, 262.
Anæsthetic Committee of the British Medical Association. Criticism of the report of the, 506.
Anaphrodisiac in gonorrhœa, 619.
Anatomical researches in regard to cæcum and its appendix, 558.
Anthrax successfully treated by local injections of pure carbolic acid, 231.
Antidotes for iodism, 456.
Antimalarial philosophy, 534.
Antitoxin. Harmful effects of, 482.
Aneurism of the aorta treated by the insertion of the permanent wire and galvanism (Moore-Corrade method), with a report of five cases, 204.
Ankylostomiasis thymotal. A new remedy for, 535.
Appeal for funds for the endowment of Queen-Empress or Victoria scholarships, 290.
Appendicitis and dysmenorrhœa. Relation between, 345.
Appendicitis and intestinal worms, 589.
Appendicitis in the female, 647.
Appendicitis. Responsibility of, 398.
Appendicitis. Some facts, medical and surgical about, 424.
Appendix. Safest method of removing the, 231.
Applicants rejected for life assurance. After-history of, 455.

Appointments. Two important Calcutta medical, 421.
 Apology for lectures. An, 265.
 Antitoxin superstitious, 649.
 Anti-scurf pomade, 347.
 Aortic aneurism. Treatment of, 423.
 Army Medical Service. Reforms in the, 41.
 Armstrong, James. Sentence of, the bogus M. D. man, 171.
 Arrested labour from distended bladder in foetus, 98.
 Arsenic. Action of, on the skin, 594.
 Arsenic and insurance, 234.
 Arsenic in beer, 611.
 Arsenic in malignant tumors, 179.
 Arsenic in the Marsh case, 74.
 Arterial duct. Persistence of the, and its diagnosis, 423.
 Arterio-sclerosis. Its clinical aspect, symptoms, course and treatment, 292.
 Articles of diet in the treatment of disease. Relative value of, 75.
 Artificial feeding. Relation of scurvy to recent methods of, 481.
 Artificial respiration. Fourteen and-a-half hours, in a child one week old : recovery, 201.
 Artificial Vichy-water, 126.
 Ascites in cirrhosis. Treatment of, 451.
 Asthma. Dyseptic, 343.
 Assistant Health Officer. D. R. Sen, Calcutta Corporation, 529.
 Assistant surgeons of the Straits Settlements Medical Service, 94.
 Ataxia, locomotor. Iodides in, 48.
 Ataxic patients. Treatment of, by co-ordination exercises, with demonstration of two patients, 17.
 Athrepsia infantum marasmus of wasting disease, 645.
 Atropine. Treatment of intestinal obstruction by, 322.
 Atropine poisoning, 401.
 Atrophy. Malassimilation of food in, 646.
 Aural tuberculosis, 147.
 Autocrats. Humour the, 691.
 Auto transplantation of ovary, 504.
 Autopsies of suicides. Three hundred, 481.
 Aural anaesthesia. Eucaine for, 348.
 Average girl. Menstrual condition of, 504.

B.

Bachelor doctor, 553.
 Bacilli. Acid resisting, in the lower animals, 124.
 Bacillus coli communis. Toxicity of different specimens of, 426.
 Bacillus coli communis, 269.
 Bacillus of articular rheumatism, 648.
 Bacillus X. (Sternberg). Comparative study of the biological characters and pathogenesis of bacillus icteroides (Sanarelli) and the hog-cholera bacillus (Salmon and Smith), 558.
 Bacteræmia, acute, and pyæmia, Chronic bacteræmia. The indications for hysterectomy and the indications for abdominal section and drainage in puerperal infection, 372.
 Bacteræmia, acute. Hysterectomy for, 669.
 Bacterial diagnosis of the gonococcus, 273.
 Bacterial toxins, 592.
 Bactericidal power and the alkalinity of the blood in leucocytosis from intoxication by mineral poisons, 295.
 Bacteriology and religious rites, 480.
 Bacterium coli. Nature of infection : contribution to the knowledge of the, 399.
 Bad meat. Death in, 593.
 Bad spelling and careless dispensing cause death, 68.
 Banish the mosquito. To, 263.
 Banana flour, 270.
 Barber's itch (tinea sycosis), 560.
 Basophilic granulation in red blood corpuscles, 149.
 Bastardy case. Communications to physicians in, 74.
 Beer drinking and kidney disease, 454.

Beer. Poison in, 69.
 Bengal Medical Gazette, 25—103—128—182—211—272—326—377—405—459—484—511—538—566—595—652—702.
 Beware of the mosquito, 289.
 Bile and its composition, 648.
 Bile in the urine, 73.
 Bile. New test for, 617.
 Biliary passages. Surgery of the, 668.
 Biological studies with reference to pathology, 46.
 Birth after vaginal and ventral fixation, 232.
 Blackmail. Protection against, in the United States, 229.
 Blackwater fever, 614.
 Bladder. Opening the, 557.
 Blastomycetes. Researches in the etiology of cancer and the pathogenic, 207.
 Bleorrhagic dysuria. For, 348.
 Bleorrhoea is not caused by the gonococcus, 646.
 Blistering fluid for horses, 151.
 Blisters. Treatment of, 147.
 Blood in the head. Some experiments of the relation between audition and the circulation of the, 46.
 Blood in the urine and the diagnosis of its source, 480.
 Blood of various animals. Method for the differentiation of the, with special reference to the demonstration of human blood, 649.
 Blood-letting in pneumonia, 594.
 Blood stains. Identification of blood corpuscles in, 648.
 Bogus American diplomas, 92.
 Bogus American diplomas. Two Armstrongs convicted, 448.
 Bogus degrees. Sir Mackworth Young on, 15.
 Bogus diplomas. Quacks and medical registration in India, 610.
 Bogus doctors, 143.
 Bogus medical degrees. Sale of, 369.
 Bogus medicine, 172.
 Bombay Medical Gazette, 25—50—103—128—154—211—239—272—326—351—433.
 Bone shaft fractures, 503.
 Book reviews, 50—299—405—651—675—701.
 Bowel lesion of typhoid fever, 269.
 Brain. Concussion of the, 293.
 Bravery of a hospital assistant, 172.
 Bright's disease. Question of diet in, 525.
 British Medical Association and the King, 611.
 British Medical Association. Indian practitioners and the, 552.
 British Medical Register. Colonial medical qualification and the, 67.
 British Medical Register for 1901, 395.
 Bronchial and pulmonary affections. Supra-renal gland substance in the treatment of, 228.
 Bronchial glands in childhood. Contributions to the pathology of, 373.
 Brotherhood, 500.
 Brush massage, 672.
 Bubo. Abortive treatment of, 397.
 Burns. Treatment of, 590.
 Bullet embedded in the heart for thirty-seven years, 669.
 Burma Medical Gazette, 25—52—78—103—154—182—211—240—272—299—325—377—406—434—484—566—624—675.
 Buried alive : A voice from the grave ! 66.

C.

Cæcum and its appendix. Anatomical researches in regard to the, 558.
 Cæar-an section, 232.
 Cæsarean section in a girl aged thirteen, 590.
 Cæsarean section. Ten successful cases of, 425.
 Calcutta General Hospital, 500.
 Calcutta medical institutions, 613.
 Calomel. Some statements concerning, 235.
 Cancer and tuberculosis. Relationship between, 149.

- Cancer of the body of the womb. Diagnosis of, 647.
 Cancer of the uterus. Vaginal hysterectomy performed for, after results in forty consecutive cases of, 319.
 Cancer parasite, 20.
 Caecolytes. Action of, 456.
 Cardiac affections. A plea for a more rational prognosis in, 226.
 Cardiac and renal dropsy. Diuretic in, 482.
 Cardiac complications. Gravity of rheumatism in the child from the point of view of, 17.
 Cardiac stimulant, 402.
 Cardiac syphilis, 695.
 Care of the mouth, 74.
 Carcinoma of the uterus. Result of the operative treatment of, 345.
 Cataract operations. Lessons from a series of one hundred, 871.
 Catarrhal condition. Nasal spray in acute, 620.
 Caugut sterilised, ligature and the value of dry, 646.
 Care of children, 178.
 Carious teeth. For, 635.
 Case reporting. Official recognition of, in Bengal, 690.
 Cavernoma of the liver. Structure and genesis of, 177.
 Census of India, 341.
 Central Provinces Medical Gazette, 51—128—154—212—240—272—377—484—652—702.
 Cerebral congestion, 272.
 Cerebral localisation, 98.
 Certificate. Chief Justice and the Doctor's, 40.
 Cervical metritis, 72—617.
 Charity, 421.
 Chancres of the tonsils in a woman aged 63—668.
 Chemical resources of the body serving as an antidote, 73.
 Chicago medical earnings, 342.
 Chief Justice and the doctor's certificate, 40.
 Child resembling alleged father. As to, 481.
 Children. Care of, 178.
 Children. Dietary for, 455.
 Chloral and hæmorrhage, 297.
 Chloric biliousness, 608.
 Cholelithiasis. Relation of, to disease of the pancreas and to fat necrosis, 233.
 Christian medical science. Proposed legislation against, 342.
 Christian scientists. Compulsory examination for osteopaths and, 420.
 Chronic coryza in an infant, 48.
 Chronic nephritis, 179.
 Chronic tuberculous peritonitis in child-bed, 121.
 Chrysorobin in the treatment of hæmorrhoids, 235.
 Charcoal, sterilised, as a substitute for iodoform in the treatment of surgical tuberculosis, 227.
 Cigarettes, American. The, 534.
 Circumcision, 503.
 Circumcision. Advantages of, 695.
 Cirrhosis of the liver. Etiology of, 146.
 Cirrhosis of the liver. Nature and distribution of the new tissue in, 149.
 Civil medical work in India, 585.
 Claims on, and dues to, I. M. A. Provident Fund, 641.
 Cleaning of teeth, 47.
 Cleaning public buildings and conveyances. Proper and improper methods of, 559.
 Coated tongue, 665.
 Cocaine. A stable solution of, 428.
 Cocaine habit of ten months' duration treated by complete and immediate withdrawal of the drug, 374.
 Cocaine. Subarachnoid injections of, 344.
 Cold as a therapeutic agent, 401.
 Colonial medical qualifications and the British Medical Register, 67.
 Coma of diabetes, 530.
 Communications to physicians in bastardy case, 74.
 Composition of Indian cows and buffaloes' milk, 93.
 Compression of the ureters by myomata uteri, 72.
 Concussion of the brain, 293.
 Condition syrup for horses, 151.
 Condylomata. For, 126.
 Constipation in children. For, 456.
 Consumptives. Almora as a health resort for, 643.
 Contagiousness of leprosy, 618.
 Contusion, 696.
 Contusion injury to the eyeball. Case of, followed by fulminant glaucoma: recovery without operation, 453.
 Conservation of energy, 499.
 Convulsions, infantile. Etiology of, 146.
 Corns. Treatment of, 271.
 Corpuscles. Bæophilic granulation in red-blood, 149.
 Correspondence.—American medical frauds, 24—Army medical services: why it is not popular, 560—Assam oils a substitute for tea, 153—Assistant Surgeons and the Indian Medical Service, 236—Assistant Surgeons, Bengal. "THE TEMPTATION OF SKILL" WITH SPECIAL REFERENCE TO OPERATIVE GYNÆCOLOGY.

By **EUGENE COLEMAN SAVIDGE, M. D.,**

Attending Gynecologist, St. Mark's Hospital; Assistant Gynecologist, Roosevelt Hospital, Out-Patient Department, New York U. S. A.

THREE opinions upon specialists are to the purpose of my paper. One is from a bright society woman, knowing the before and after of surgery in her large acquaintance of women. Another is from an exceptionally keen lawyer, an adept at psychology, a searching dissector of men and motives. And the third is from a gynecologist who has himself done considerable radical work.

Said the woman: "Do not female specialists often get beyond themselves in their anxiety to haul and out and sew the internal organs of women?"

Said the lawyer: "The temptation of skill is so great that it cannot be safely disregarded in accepting the verdict of our leading surgeons. The general medical consultants defer so entirely to the specialist that no new light can be had from them. One knows not what to do." As family head, he was debating whether to accept the opinion of leading specialists that an abdominal section was necessary for a relative.

Said the gynecologist: "The operation of hysterectomy has become almost perfect. The French are so expert that child-bearing has become a grave question in France, and the government is giving pensions to those of large family. The government would do better to pension its surgeons, and thus save the child-bearing powers of the women."

Among medical men as well as among the laity the opinion is growing that specialists have been operating too much. The crowd and enthusiasm at a recent meeting of the New York Academy of Medicine, called to consider this very point, showed how warmly those qualified to judge the subject are feeling.

Do the general consultants abjectly defer to the specialists in deciding for or against an operation? Are surgeons unduly subject to the temptation of skill? And is this reaction and protest an unmixed good? No one comprehending the motive of my paper will call me an apostate to my specialty.

Woman's Debt to Gynecology.—The debt that woman owes to the surgical audacity of man is beyond computation. Disgusting troubles, heretofore hopeless, are now cured as daily routine. Life-threatening, life-taking afflictions—perils formerly not even known to exist—can now be diagnosed and removed by the hospital interne. Take, for example, reports covering four years' work on the single life-menace of ectopic gestation: HENNIG reports 122 cases; CAMPBELL, 75 cases; MARTIN, 77 cases; PARRY, 214 cases. As other operators throughout the world have fallen upon a like number of cases, formerly surely fatal and now entirely curable, the army of women now living, who would be under the sod but for gynecology, can be calculated. The

ability to attack this one malady would redeem the specialty if it had accomplished nothing else. The women saved from death by pedicle torsion and intra-peritoneal ruptures would likewise make an imposing array. If we could assemble these women at Chickamauga camping-ground, and marshal them into army corps—these lives literally given to the world by the new specialty—gynecology would have militant numbers behind it when placed "on the defensive," as it now undoubtedly is.

Gynecology a New Specialty.—I emphasize the newness of the science of the diseases of women. Its newness will explain why some of its work has been tentative. It will repay one to hunt for the scant literature of the subject appearing before 1860. Formerly, the vaguely conceived troubles of females, not formulated in any text-book, were treated upon the medical divisions of hospitals, and were briefly discussed in the medical colleges at the close of the obstetric course by the professor of midwifery.

Goodell, the First Professor in Gynecology.—GOODSELL, of Philadelphia—a contemporary—held the first Chair of gynecology ever established in a medical college. Other colleges followed the University of Pennsylvania in establishing the new professorship; text-books were written; a few hospital beds were set aside for diseases peculiar to women—and from the MARION SIMS tent in Georgia the movement grew to the dignity of the Woman's Hospital in New York.

The French Academy on Ovariectomy.—Germany, France and England joined this American movement. Yet we read that in 1856 the French Academy condemned the operation of ovariectomy. Imagine the weight of the authority of the Academy, and the audacity of the pioneers who dared say that the respected leaders were wrong.

Operative Activity in the Virgin Field.—Under presumptuous leadership the new science evolved. It transferred completely a large body of patients from the medical man to the surgeon. A crop of new specialists sprang up, all eager for skill and glory. The field was so virgin that each bright mind had a new device or a new instrument to carry his name down the surgical corridors of time. Operative activity became immense. The men with hospitals averaged about a hundred abdominal sections a year. Even small towns caught the enthusiasm, and young men felt the odium attaching to the inability to report a hundred "sections." Surgeons even paid the way of patients through hospitals for the privilege of operating upon them, and for a time all patients who did not die were reported as successes.

Changing Ideas.—A living patient after operation was the primitive goal. A certain number of operations were required to establish how few women would die under abdominal section. And this is about all the information to be drawn from statistics. They cast no light upon whether the last condition is better than the first; whether benefit has been conferred upon the patient.

The reaction came. Women who had been led to expect so much from the new and miraculous operations

found 'their way back to the dispensary or consulting-room. In one thousand cases applying to me for gynecological treatment, nearly one-tenth were women who had already been operated upon. These ailing post-operative cases among the sick women form a tremendous propaganda against the operator, and have much to do with placing the specialty "on the defensive."

The work of the statistic maker—a brave and priceless work—is done. He has established how many cases can live after operation. There it stands, 'this operative possibility—tried, justifiable, and ready for use. That question settled—the practicability of the procedure—the profession has passed to the next issue: What cases require this effective measure? Realizing how entirely tentative was much of the work reaching up to this point, the professional mind has been driven to the other extreme of conservatism. That this reaction is an unmixed good is far from true, as any one must feel who has stood beside a dying patient, lost for the want of a knife thrust.

What, briefly, may be considered the latest conservative view regarding operations upon women?

Reparative Work.—There ought to be no dispute about any work of repair. Even the day-laborer will hunt the doctor to stitch a gaping wound. A woman should have the subject of repair presented to her in the same aspect.

Laceration of the Perineum.—Take, for example, a laceration of the perineum. Authors differ in their estimate of its frequency. Some place it as high as one-third in primiparae, no matter what device for its prevention is attempted. The writer, favored by the character of the cases, succeeded in getting as low a percentage as 4.5 per cent. at the Sloane Maternity Hospital, and this record was beaten in less than a year by a succeeding interne at that institution. In private practice ten per cent. is a good showing. These lacerations, too extensive to be remedied by nature or by the obstetrician's casual suture, should be carefully repaired; likewise an over-distention of the vaginal wall. If it is neglected, there follow prolapse, erosion, varix, and all the disorders attending pelvic congestion. Pelvic congestion is a serious menace to longevity.

Lacerations at the Cervix.—Lacerations at the neck of the womb have occasioned much hard feeling in the profession, and have given rise to many misunderstandings among patients. The profession would do well to enlighten women about lacerations at the neck of the womb. We should tell why it is beyond our power to prevent them, and why there is even no practical device known to the profession for so doing. We should teach that many will heal spontaneously if attention is paid to them during the months following confinement; that it is by no means settled as wisdom to sew them at the time of confinement; and that the doctor who tells a patient with such trouble that she was "neglected in confinement" is either dishonest, or means that the patient neglected herself after she dismissed her obstetrician, by failing to have local attention. If women were so enlightened, it would be less easy for a contemptible medical

thief to poison the mind of a patient against the man who carried her conscientiously through a wearisome confinement. Nor would it be deemed a confession of bungling to tell of a laceration needing attention. Then all might receive attention, fewer would require operation, and none need be passed silently to avoid criticism. Such lacerations when neglected may bring catarrh, metritis, sterility, nervous troubles, tubal involvement, and pelvic congestion. And how often is this condition, which is a progressive development made possible by the patient's neglect of herself, charged years afterward to the carelessness of the obstetrician!

Result of Neglect during the Three Months Following Confinement.—A soggy, subinvolved womb will swell at times as much out of shape as a dropical leg or abdomen; and a nick that would otherwise heal and leave no more trace than a shaving-wound of the face, is thereby exaggerated, rendered indolent, and made to granulate into a scar. Lack of attention to the womb during the three months following confinement is where the neglect occurs. This point cannot be accented too strongly. When women know it, and act on the knowledge, trachelorrhaphy will be practically banished from gynecology, and operations for retrodeviation will become rare events. But until this is thoroughly understood, there will remain numerous cases needing repair. And no one who has seen the repair rightly made in proper cases will dispute the brilliant result. It puts to flight almost invariably the aching back and side dependent upon the trouble.

Curettage.—Curettage is really reparative work, and, when rightly done, is the most important procedure in gynecology, upon the basis of life saved. The name does not adequately describe the procedure. The scraping of the uterine walls is the least important point. Many blunder through misconception on this point. One could better dispense with the very instrument of curette which gives the operation its name, than to disregard the fenestrated forceps, or lose sight of the aim of each curetting. For the procedure is designed to examine for diagnosis, to empty, to irrigate, to drain, to pack for stimulation, to contraction, as well as scraping, a relatively minor matter. In many of the most successful cases of "curettage" the curette is hardly needed, as, for example, the removal of matter in milk.

Immediately after abortion this procedure—this examination—is imperative. Some obstetricians dissent and urge the expectant treatment. But the reply is that the expectant treatment guesses and hopes that nothing has been left behind, while the operative plan sees—with the instrument, of course—that all is well. Most of these cases treated expectantly come ultimately to the gynecologist, and many demand formal curettage after months of exhausting blood loss.

In cases of sepsis after abortion, criminal or otherwise, there can be no possible debate about the immediate necessity of cleaning out the infected centre. The physician falling in with a case of criminal abortion is really imperilling good life chances if he waits to see whether the patient will die or get well before he decides whether his treatment shall be to notify the coroner or to continue in expectation. This is so self-evident that it is trite; yet it is what occurs all the time.

In sepsis after child-birth, the procedure should be resorted to as often as necessary, though with precision each time. Nothing could be more dangerous than simply stirring up foul matter in a soggy womb. Only the formal operation should be undertaken, and this with a thoroughness which implies something more than merely scraping uterine walls. The following case will illustrate: The writer was called to remove the uterus of a post-partum case green with sepsis. She had received curettage some days before from a prominent operator, who had since been called from town. It was therefore thought that ultimate benefit had been derived from curettage. Nevertheless she was once more formally curetted; the pulse and temperature came down; and the life seemed saved. A few days later, however, up went pulse and temperature, and the patient again became green. This time the first operator, having returned to the city, curetted the patient for the third time, and she recovered. The lesson is plain.

The Curette and the Pus Tube.—While no one hopes to draw off pus tubes by curettage and drainage, it is surprising what huge, perimetrial masses do disappear after the operation. Nature puts a hard fortress of induration between infection and the rest of the body, and any one who has seen the swelling of a bee-sting come down after the minute source of infection has been removed will comprehend the analogy in the broad ligaments. Frequently major operations—double salpingo-oophorectomy for small fibroids—have failed to relieve uterine hæmorrhage until the secondary operation of curettage has been done. The writer has often felt convinced that curettage at the start would in some cases have obviated the more dangerous procedure. Much of the benefit following plastic work and operations for retrodeviation can reasonably be credited to the accompanying curettage. In skilful hands the curette never endangers life.

Dilatation of the Cervix.—This is another function-conserving, non-life-endangering operation. It gives brilliant results in antelexion following infantile uterus; and in antelexion and stenosis as a penalty of congestion and auto-infection, or following the infectious diseases, or from external infection—a condition of dysmenorrhæa, muscular cramp at the cervical bend, and sterility. While sterility is not always overcome by the procedure—for there is the male element involved as well as the additional question of tubo-ovarian integrity—there is almost always relief from pain. The patients express themselves as feeling "lighter."

Also, I have noticed that almost invariably when the sensual sense and power of orgasm have been lacking in women with the knotty, antelexed type of uterus, dilatation has bestowed both; and this endowment is sometimes of importance in some families.

Operations Precluding Debate.—It is, therefore, not the "surgical itch," nor the "temptation of skill," but rather sound conservatism, which leads gynaecologists to urge the operations described. We now pass to a larger class of work.

Specific Operations for Retrodeviations.—I have elaborated this subject in a recent paper on "Retrodevia-

tions." I have the temerity to venture that few of these operations will be done by the next generation of gynaecologists. There are several reasons. Gynaecology has flourished upon the neglect that patients entail upon themselves after confinement. Patients are being enlightened, and the gynaecological surgical harvest is already dwindling in consequence. Second: enlightenment in preventive gynaecology—the growing branch of the specialty—will induce those patients who acquire retrodeviation in spite of effort to select "the cheaper, better, safer plan of recurrent treatment" for retrodeviation in all cases in which this plan gives satisfactory results, and in which the patients have sufficient intelligence to weigh inevitable alternatives. Of course this is a prospect which will be combated by those whose chief skill and income lie in the direction of retrodeviation operations.

Cæsarean Section, Symphysiotomy, Craniotomy, etc.—These are domestic and religious questions. As the new science becomes more evolved—as women become more enlightened—there will be fewer of these except among the ignorant and self-neglectful, and by deliberate choice. Military and naval careers have certain physical requirements which are not guessed at. Matrimony and maternity are as important, and we should not guess and hope about pelvic conjugates. The religious and domestic question settled in the case of obstruction discovered at term, there is no doubt, even in the lay mind, about the necessity of getting the child out. These operations are ruled out of the debate.

Abdominal and Vaginal Section.—Abdominal and vaginal section (including ovariectomy, salpingo-oophorectomy, and hysterectomy) make up the class of work in which the fame of every prominent gynaecologist has been won. And this is the field of the sharpest debate. Some of these operations urged by gynaecologists—as for epilepsy and the psychoses—are characterized as criminal by others. Let us narrow the field.

Malignant Growths.—A malignant growth, all agree, should be removed as promptly and as thoroughly as possible, together with all contiguous tissue likely to be invaded. There can be no debate, if the diagnosis is clear, about the necessity for operating for the rupture of a pus sac or blood-vessel, or the torsion of a pedicle, or the rapid absorption of poison from an infecting centre, or the strangulation of an intestine or excretory duct by pressure or otherwise. Delay is death, and although the operation may endanger life up to ninety-nine per cent., and destroy a function, and spoil some fancy statistics, this is the lesser evil. Wretched is the man who allows either his statistics or habit of conservatism to delay radical measures!

Ectopic gestation, likewise, requires prompt attention, and the subject precludes debate.

The Debate on Appendicitis.—Appendicitis is quite related to the purpose of the paper. Surgeons admit that seventy-five per cent. of all cases will recover without operation, but claim that ninety-eight per cent. could be saved by operating promptly on every case as soon as discovered. This discloses a debate of great significance, for physicians are disinclined to turn all cases to the surgeon. MORRIS has estimated that there are two

hundred thousand new cases of appendicitis discovered each year in the United States. If this is true, and the surgeons are right, forty-six thousand of them would be ruthlessly sacrificed under medical treatment. But physicians assert (and I wish I knew whether truly or not) that autopsies upon subjects that have died from other diseases than appendicitis show old inflammatory processes about the appendix in one-third of the cases just as old tuberculous cicatrices are found in the lungs where tuberculosis has never been suspected. In other words, one-third of all coming to the autopsy table, and by inference a large proportion of the population, have gotten well spontaneously from an unsuspected trouble which would have subjected them to a life-endangering operation had they fallen into the hands of a surgeon of sufficient skill to make the diagnosis.

When surgeons extol the skill necessary to make diagnosis in doubtful cases, physicians retort that these are the cases in which diagnosis would better not be made. Obviously the subject has not crystallised, and is in process of evolution. But even the laity clamour for an operation when there is recognized tumour and poisoning from pus absorption.

Small Fibroid Tumours.—I come now to the less urgent cases of small fibroid tumours, swollen and tender fallopian tubes, ovaries, etc. These are the cases which walk about with slight disability, hope for a miracle from an operation, and spread distrust of the surgeon when they find it does not come.

Remembering the dangers from fibroids—pain, hæmorrhage, growth and pressure symptoms; and malignant or septic degeneration—there is some justification in operating upon them in the improvident and self-neglectful as soon as discovered. And some operators adopt this plan. But the more intelligent—those again who can weigh inevitable alternatives—can often be carried under observation to the time of life when fibroids frequently disappear. Nor is it wise to sneer at hope of benefit from treatment. Many tumours do grow steadily smaller under treatment, and some have disappeared entirely. But consent to temporize should be given only upon the well-understood condition of constant observation, for even conservatism prompts early operation in all cases in which the growth steadily increases.

The Menopause and Fibroids.—The menopause does not bring relief for all fibroids; many give their worst symptoms thereafter. Some operators report that nearly half their hysterectomies for fibroids were upon women over fifty years of age. The earlier, therefore, that an inevitable operation is done, the better are the size of the tumour, the extent of the adhesions, and the condition of circulatory system. Yet many operations can be avoided by constant supervision.

Small Pus Tubes.—Pus in the fallopian tubes often gives less evidence of its presence than pus in any other portion of the body. It has often been discovered by accident, having given no symptoms. All operators have seen supposed pus tubes prove to contain an exudate capable of absorption. Many of us have had patients, who obstinately refused operation for pelvic masses, return to us after five or six years without treatment, with pelvis entirely clear.

Radical or Conservative Surgery.—Assuming recurrent attacks of pelvic peritonitis and a pus tube, what then? Suppose we had an abscess of the liver, or finger, or foot; would we not follow the gynecological practice of nice, clean, exhaustive, and effective removal of everything possible in the neighbourhood, because of future septic possibilities? By no means. Instead of spending an hour digging around the peritoneal cavity, making peritoneal toilets, we can make an incision, drain, get a scar, and save a function. An incision through the vagina into a pus cavity does sometimes leave a troublesome sinus—especially if such pus cavity be a fallopian tube—and sometimes does not reach trouble further up. And both of the conditions may require a later abdominal section to clear up. But the brilliant results in most cases—some done without ether—compared with the mortality and post-operative condition in patients after radical operations, make it worth while to consider this mode of weeding out the unnecessary radical operations. The man who disregards the importance of function confesses ignorance of psychology, and has not frankly admitted to himself the post-operative condition of his patients. Yet I have known patients to be absolutely implored and threatened for permission to do the radical operation, who have been made perfectly comfortable by vaginal puncture without ether.

Salpingo-oöphoritis; Enlarged and Tender Ovaries and Fallopian Tubes; Cystic Ovaries, etc.—In the evolution of gynecology, many cases of passive congestion and muscular debility have been treated by ovariectomy, and have been helped by the operation. Patients of this class have consulted gynecologists month after month for a pelvic soreness which "treatment" only temporarily assuages, and finally in discouragement have consented to "have something done"—the something meaning an abdominal section.

In a paper on "The Feminine Element in General Medicine," the writer has treated of this neglected subject of passive congestion of the pelvic and abdominal organs. It comprises a congestion—almost an erectile condition—of ovaries, tubes, rectal veins, liver, kidneys, and spleen, and the soreness it brings is entirely analogous with the pain in the breasts near the menstrual epoch. Some women have breasts as sore as boils at these periods—yet breasts have not been made the subject of operative furor on this account. This pelvic condition goes to form the diagnosis of "salpingo-oöphoritis." Most of the benefit from the operations for this condition is derived from "the rest in bed, the special care given an invalid after operation, and the mysterious change in nutrition that follows the use of the knife or curette." We can modify this disordered condition of circulation without the use of the knife, and bring tonicity to these dilated and aching veins. And when a surgeon laughs incredulously at thus modifying veins, ask how surgeons succeed in modifying such stubborn tissue as bone by extension apparatus, and in orthopedic work like the relief of spinal curvature.

The Debateable Operations.—These light and debateable operations give the fancy statistics. They are so easy to do. They fascinate. They flatter a man with the idea that he is a skilful surgeon—more skilful than one who

does heavier work and gets a larger mortality. There are also the cases that have given ground for reaction against operations that may cost some lives. In allowing one's mind to drop into a conservative attitude toward surgery, one must see to it that it is only toward those cases in the debateable list. This list is small and easily grasped. It is trifling with life and health to defer any of the other operations of gynaecology when demanded.

The tentative paths, tried and abandoned by the pioneers in our new science, are not to their discredit. But for them the straight road would not appear so plainly on the chart. All honour, then, to the brave men who have built up in our own time an almost perfect science of diseases of women!

(We strongly recommend the careful study of this excellent practical paper to our readers.—Ed. I. M. R.)

BACTERIOLOGY OF PLAGUE.

By DAVID C. REES, M. B. C. S., L. R. C. P.,

Superintendent of the London School of Tropical Medicine.

HISTORY.

VIRCHOW, in 1879, reasoning from analogy, predicted that as plague never arises spontaneously in a locality where it has not previously existed, the disease would prove to be one of microbic origin. In the same year HIRSCH and SOMMERBRODT observed in the blood of patients suffering from plague elongated refractile granules, usually arranged in pairs. These bodies may or may not have been plague bacilli; at any rate, these observers failed to attach any importance to them from the etiological standpoint. With the outbreak of plague in Hong-Kong in 1894, independent Commissions were sent by the Japanese and French Governments respectively to investigate the disease. The former was under the direction of KITASATO and AOYAMA, and the latter under the direction of YERSIN. KITASATO almost at once succeeded in determining the constant presence of a characteristic bacillus in the buboes, blood, and organs of patients suffering from the disease. His colleague confirmed the discovery. Subsequently YERSIN, working independently, found the organism, and although the cultural characters and staining affinities which he described for his bacillus did not agree with those published by KITASATO, there is no doubt that they were both dealing with the same bacillus. There have been since 1896, unfortunately, only too many opportunities in India and elsewhere for confirming KITASATO's discovery.

GENERAL CHARACTERS OF THE BACILLUS.

The micro-organism resembles somewhat closely the bacillus of chicken cholera. It is a small bacillus, measuring from 1 to 2 in length, and from 0.3 to 0.5 in width. Larger forms are often met with, which may measure as much as 4 or 5. It possesses rounded ends, giving it an oval appearance. It is usually regarded as being non-motile. KITASATO, however, states that if it be examined in media kept at a temperature of 37°C., it can then be observed to be actively motile. GORDON has also described the presence of one to two terminal spiral flagella. In cover-glass preparations made from blood and sputum it is frequently seen to be arranged in pairs. In fresh broth cultures it

tends to form streptococcus-like chains made up of from five to six short bacilli. These chains are sometimes observed in the sputum. Involution forms are frequently met with; these occur generally when the bacilli are existing under unfavourable conditions—for example, when they are present as a mixed infection in buboes, or in old broth or agar-agar cultures. They may be thickened, pear-shaped, or spindle-shaped. HAWKIN found that these forms appeared in an agar-agar culture to which 2.5 per cent. to 3.5 per cent. of salt had been added, and he regards this as a point of some diagnostic value. The plague bacillus does not form spores, and it has no true capsule, although in some stained specimens an appearance suggesting encapsulation is present. It is a facultative anaerobe.

STAINING AFFINITIES.

It stains readily with the ordinary aniline dyes, but is decolorised by GRAM's method. In cover-glass preparations made from buboes, blood or organs, the bacillus stains more intensely at the ends, giving rise to a bipolar appearance. Laboratory cultures may exhibit this feature, but they do not always do so. Good routine stains are weak carbol fuchsin (one in four), LOEFFLER's blue, and weak gentian violet. The bipolar appearance can be generally best brought out by overstaining with strong carbol fuchsin for four or five minutes, and then carefully decolorising in absolute alcohol. The plague bacillus shows a great affinity for the thionin group of stains, such as carbol thionin and toluidin blue, and these are excellent for staining blood and sections of organs and glands.

CULTURAL CHARACTERS.

The micro-organism grows well on the ordinary media, including blood serum, gelatine, agar-agar, glycerine, agar, and broth. Agar-agar and broth are those usually employed, especially in the tropics, where gelatine is unmanageable. It grows well at 37°C., but also equally well at 25°C. to 30°C., so that in a hot climate an incubator may often be dispensed with. On blood serum it grows rapidly, and in from twenty-four to forty-eight hours a slightly elevated, moist, cream-coloured growth appears. In gelatine it forms an opaque white growth with irregular margins. The growth tends to be limited to the needle track; it causes no liquefaction of gelatine. On agar-agar, or better on glycerine agar, it grows readily, forming an abundant, moist, shining, cream-coloured growth, presenting a markedly crenated appearance. If touched with a platinum needle, it is found to be smooth and sticky, and freely moveable on the subjacent culture medium. If carefully dried slanting agar cultures be inoculated, by spreading the culture material evenly over the surface, a somewhat characteristic growth appears. The surface becomes closely covered with minute translucent colonies, and if viewed from behind, the whole presents the appearance of ground glass. The agar-agar tubes may be dried in a desiccator, but preferably in an incubator, for one or two weeks until all the water of condensation has disappeared.

In ordinary bouillon it gives rise at first to a general turbidity. This rapidly clears, with the formation of a fine flocculent deposit on the bottom and sides of the tubes.

HAFFKINE'S STALACTITE GROWTHS.

HAFFKINE has discovered a highly characteristic appearance in bouillon cultures under certain conditions which, so far as is known at present, is peculiar to the plague bacillus. He found that if broth cultures, preferably those to which a small amount of fat has been added, be kept absolutely still and free from any vibrations, a growth appears on the surface of the broth, which spreads down into the media in the form of long stalactites. HAFFKINE uses an ordinary narrow-mouthed flask half filled with neutral or faintly alkaline peptone broth, to which a little coconut or olive oil or ghee (clarified butter) has been added. After sterilising, it is infected and placed in an incubator reserved for the purpose. In India the ordinary room temperature suffices. In twelve hours' time a diffuse cloudiness appears, and this is gradually replaced by the formation of the stalactite growth which hangs from the surface, and may reach to the bottom of the flask. If it be shaken, the stalactites fall to the bottom, giving rise to the so-called "snowflake" appearance. If the flask be incubated again, the stalactites reform. The characteristic growth can be best observed by placing it in the dark and holding a light behind it.

The micro-organism grows on potato, but not characteristically. It forms a small amount of acid in sugar-agar, and causes coagulation of milk in about two weeks (KLEIN).

ANIMAL EXPERIMENTS.

Apes and rodents, including rats, mice, guinea-pigs, marmosets, and bandicoots, are all highly susceptible to inoculation of the plague bacillus, and most of these animals have been observed to suffer from the disease under natural conditions. Sheep, goats, cows, and horses are susceptible to a slight degree; dogs and cats react very slightly; birds, and also swine, are refractory to repeated inoculations. A rat or guinea-pig, which has been inoculated with plague material, shows within one to three days—usually on the first day—evidence of toxic poisoning; it refuses food, its coat loses its gloss, respirations become hurried, and the animal in many cases staggers or shows weakness in the hind quarters, and finally rolls on its side and eventually dies, either with or without the occurrence of convulsions. On *post-mortem* examination, inflammatory oedema is usually found at the site of inoculation; there is marked congestion of the spleen, liver, and lungs, and these organs frequently show scattered hæmorrhagic patches. The spleen and liver are enlarged. The glands also are enlarged, but not as a rule, to a striking degree. The bacilli are present in large numbers in the spleen, liver, and blood.

EVIDENCE THAT THE BACILLUS CAUSES THE DISEASE.

That the micro-organism which has been described is the causative agent of plague is at the present time undisputed. Proof rests on the following facts. The bacillus is constantly present in the body of an individual suffering from the disease. If from this individual material be taken which is found to contain the characteristic bacillus, and be inoculated into a susceptible animal, the animal sickens and dies, and the micro-organism can be obtained from its spleen and other organs. The bacilli thus obtained will in their turn prove

to be fatal to other susceptible animals. Several striking examples have been quoted by CLEMON, from India, tending to show that man and rat infect one another under natural conditions. As, however, his observations were made in districts where plague was raging at the time, they cannot be accepted unreservedly.

Accounts of successful direct inoculation experiments from man to man are also on record. Thus, in 1802, Dr. WHYTE infected himself with plague material and died of the disease; in 1835, in Cairo, two condemned criminals were inoculated with blood obtained from an individual suffering from the plague; they both contracted the disease, but recovered. The same objections, however, apply to these experiments as have been already raised against CLEMON'S observations. The outbreak in the laboratory in Vienna (1898) is, however, more conclusive. The attendant who had charge of animals inoculated with plague contracted the pneumonic form of the disease and died, the bacilli being present in his sputum. The two nurses who attended this man contracted the disease as well as Dr. MULLER; the latter died.

THE EFFECTS OF HEAT, DRYING, DISINFECTANTS, ETC., ON THE BACILLUS.

The plague bacillus does not, speaking generally, possess high powers of resistance outside its vertebrate hosts. Thus, it is readily killed by direct sunlight, by disinfectants, and by rapid drying at a high temperature. To slow drying, at a low temperature, it is more resistant. The micro-organism is, therefore, more readily killed in a hot, dry climate than in a damp, temperate one. Pure cultures which are protected from light and drying may retain their vitality for months. It is extremely resistant to cold, and cultures which have been exposed to a temperature below freezing point have been found to be alive after four months. Laboratory cultures soon lose their virulence, but by passing them through susceptible animals it can generally be restored.

The German Commission gives the following results of experiments relating to the vitality of the bacillus outside the body. Their figures do not agree in every instance with those in the reports of other Commissions, but it is probable that varying conditions of climate and technique may account for some of the differences:—

A thin layer of culture material spread on a cover-glass and exposed to direct sunlight	
is killed	... in 1 hour.
Cultures heated to 70° C.	... in 10 minutes.
" " 80° C.	... in 5 "
Cultures treated with corrosive sublimate (1 in 1,000)	... at once.
Cultures treated with carbolic acid (1 per cent.)	... in 10 minutes.
Cultures treated with carbolic acid (2½ to 5 per cent.)	... in 1 minute.
Cultures treated with lysol (1 per cent.)	... in 5 minutes.
Cultures treated with chloride of lime (1 per cent.)	... in 15 "
Cultures treated with quicklime (1 percent.)	... in 30 "
Cultures treated with sulphuric acid (1 in 2,000)	... in 5 "
Cultures treated with hydrochloric acid (1 in 1,000)	... in 80 "
Pieces of organs, dirt, dressings, etc., infected with plague bacilli (in India)	... in 8 days.
Ditto (in Germany)	... in 14 "
The bacilli in urine and faeces	... in 5 "
" sputum	... in 10-15 days.
" tap water	... in 5 days.
" sterilised water	... in 10 "

MODE OF COMMUNICATION.

Inasmuch as the micro-organism does not produce spores, and possesses such low powers of resistance outside the body, it is improbable that infection takes place to any great extent directly through the air; it must under ordinary circumstances take place by close contact. The micro-organism may gain entrance to the body by any or all of the following ways:—

1. By the skin or mucous membrane.
2. By the respiratory tract.
3. By the gastro-intestinal canal.

1. *By the Skin.*

This is the commonest way, and probably the only one, in bubonic cases. Infection may take place through wounds, scratches, or insect bites. The Austrian Commission states that it succeeded in infecting a rat by rubbing a virulent culture into the intact skin. The following insects are possible agents in carrying the disease: flies, fleas, bugs, ants, and mosquitos. YERSIN noticed that flies died in his laboratory in Hong-Kong, and he succeeded in inoculating a guinea-pig from a culture obtained from an infected fly. NUTTALL subsequently fully confirmed this observation. Similar experiments have been performed on ants and bugs by HANKIN and NUTTALL respectively. SIMOND has done a considerable amount of experimental work with the fleas of rats, which points to the possibility that these insects are frequently carriers of the disease to man.

2. *By the Respiratory Tract.*

It has been already stated that under ordinary conditions the plague bacillus does not exist in the air, but it is possible that in densely crowded, close dwellings the disease may be contracted by aerial infection. More frequently, however, the bacillus gains entrance to the respiratory tract by inhalation from contact with infected dressings, discharges, etc., as, for example, from an infected person sneezing or coughing in the face of a healthy individual. Experiments have proved that rats may become infected by rubbing virulent cultures on the nasal mucous membrane.

3. *By the Gastro-intestinal Canal.*

Some observers believe the disease may be contracted from infected food or water, and they regard the buboes as secondary manifestations. In favour of this theory is the fact that the bacilli are frequently to be found in large numbers in the intestines of animals fed on plague organs or on infected grain. The plague bacillus has also been isolated from water obtained from a well near a plague-infected dwelling. On the whole, however, it is unlikely that this is the way in which infection usually takes place. The Austrian Commission is inclined to believe that infection takes place sometimes through the tonsils. This may be so in those cases in which the cervical glands are those first affected.

BACTERIOLOGICAL DIAGNOSIS.

In the bacteriological examination of a suspected case of plague, the method of investigation differs according to whether it be one of the bubonic, pneumonic, or septicæmic type. In the bubonic form the bacillus must be looked for in the buboes; in the pneumonic form in the sputum; and in the septicæmic form in the blood.

Method of Obtaining Material.

When dealing with sporadic cases, or at the onset of an epidemic, the bacteriological examination requires to be undertaken with care and systematically. During an epidemic, however, a provisional diagnosis can often be made by simple examination of cover-glass preparations made from the gland, sputum, or blood, as the case may be. In bubonic cases of ordinary severity the inflammation is very acute, usually of a hæmorrhagic character, with marked exudation and infiltration into and around the affected gland. In these cases a sterilised antitoxin syringe should be plunged into the gland when a sufficient quantity of fluid can be readily

obtained. In mild cases, where the inflammation is more chronic and softening of the affected gland often absent, it is preferable to make a small incision (with aseptic precautions) and remove a small piece of the gland, which is placed in a sterilised tube for subsequent examination.

In pneumonic cases the sputum should be collected in the ordinary way, and not mixed with any antiseptic material.

In septicæmic cases it is best, in order to exclude the possibility of skin contamination, to remove a sufficient quantity of blood directly from a vein by means of an aseptic hypodermic syringe. It is good practice to examine the blood in all cases of plague.

Microscopical Examination of Material.

The infective material obtained from one of the above-mentioned sources should be dealt with in the following way. Two cover-glass preparations should be made, and one stained with an ordinary aniline dye, such as weak carbol fuchsin, and the other by GRAM'S method. The presence of short bacilli, exhibiting bipolar staining and tending to arrange themselves in pairs, or short chains, and which are decolorised by GRAM'S method, is highly suggestive. Negative evidence, however, is of less value, and should never be relied upon in auspicious cases. In buboes which have suppurated, the bacilli may be absent or scanty. In cases of pestis minor the affected glands may contain very few bacilli. I have observed a case of this description recently in England. It must not be forgotten that the plague bacillus frequently occurs as a mixed infection, generally being associated with staphylococci and streptococci. These, however, stain by GRAM'S method. In sputum it may be mistaken for the diplococcus pneumoniae; but this also stains by GRAM'S method, and appropriate staining reveals the presence of a distinct capsule.

In blood examination I find it best to make the preparations on slides. The bacilli are usually present in very small numbers in the peripheral blood, and a larger amount of blood can be reviewed more rapidly than if a cover-glass preparation be employed.

Cultivation.

In mixed infections endeavours should be made to isolate the bacillus from plate colonies or by employing HAFKINE'S salt medium.

Ordinary broth and agar-agar cultures should be made, and their characters studied both macroscopically and microscopically. HAFKINE'S staccite growth should also be tried. Guinea-pigs should be infected, and if they die the *post-mortem* appearance of their organs, etc., noted, and the micro-organisms should be isolated from their spleens.

It will sometimes be necessary to make sections of organs and glands in suspected cases. It will generally be found preferable to embed the latter in celloidin.

Blood Serum Reaction.

The diluted blood serum obtained from a case of plague is said to cause clumping with plague bacilli. Hitherto this has not proved of practical value. The reaction can usually only be obtained late in the disease, and even then it is not always present.

The Bacillus is Non-pyogenic.

The plague bacillus may, I think, be best regarded as belonging to the septicæmic group of pathogenic micro-organisms, that is, one which is present in the blood, and may cause toxæmia or death without local manifestations. It is parallel in some respects with the anthrax bacillus. In plague, however, if local signs are present, they occur in the lymphatic glands, whereas in anthrax infections local signs manifest themselves chiefly at the actual site of inoculation. The plague bacillus does not produce pus, but it can cause necrosis of tissue. Buboes which contain the bacillus as a pure infection may resolve or slough. If they suppurate, it is generally due to staphylococcal and streptococcal infection.

A MIRROR OF PRACTICE.

ABNORMAL CRANIAL SUTURES.

By MILITARY ASSISTANT SURGEON J. T. PARKINSON,
Civil Surgeon, Sultanpur, Oudh.

THE frontal bone, as is well known, is developed from two centres of ossification, and at birth is made up of two lateral halves. After a few years the suture between the two pieces, in almost every case, becomes obliterated, leaving no trace of the pre-existent division, the bone being now one piece. In some cases, however, a remnant of the frontal suture remains, but here only at its lowest part above the nasal spine. In very rare cases, again, it is said that the frontal suture has been known to persist through life, extending from the vertex to the root of the nose. The last condition, I venture to say, must be extremely rare, as up to the present time I had not met with such a deviation from the ordinary or normal disposition of the cranial sutures, and this notwithstanding, having performed for many years a very large number of autopsies.

On the 8th June 1900, when making a *post-mortem* examination of the body of a native female, age 50 years, I was at once struck with the peculiar disposition of the cranial sutures at the vertex of the skull. The inter-parietal or sagittal suture was seen to continue onwards through the frontal bone, distinctly dividing this bone into two lateral and equal halves by a well-marked frontal suture extending from the bregma to the root of the nose. This frontal suture was perfectly dentated the whole way through, and in appearance looked exactly like the sagittal suture as regards the formation and contour of its dentations. I attach an actual size diagram of the specimen made by a local draughtsman, which shows exactly the condition described, and in which the frontal suture is marked A.

I now come to the second peculiarity, which of course is not so uncommon as that described. In the LAMBDON suture a large Wormian bone is developed on the right side. In the diagram it is marked B. This supplementary bone appears to have supplanted a large portion of the right parietal bone posteriorly, and a small part of the occipital. It measures in its greatest length $1\frac{3}{4}$ inches, and in width $1\frac{1}{4}$ inches. In the diagram it looks smaller than it actually is, owing to the illustration showing it as it appears, looking from above.

Remarks.—There are a few points of interest in connection with the above unique example of irregularities worthy of note—

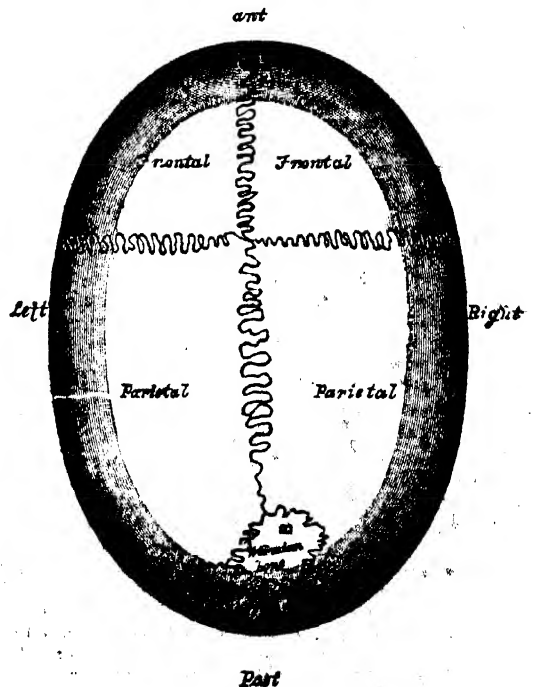

(a) The extremity of a perfect and complete frontal suture in the adult.

(b) The large size of the WORMIAN bone which was found only on one side of the head, and occurring as it did in conjunction with a perfect frontal suture in the same subject.

(c) The last, but chief, point of interest is from a medico-legal point of view, such as might arise, for instance, in cases of injuries to the head.

Given a case of scalp wound from direct violence, it would be possible, were such a wound located over an irregularly placed suture, to wrongly diagnose a fracture of the skull, by the probe or finger impinging on such a suture. Of course an exploratory incision would remove all possibility of error in such a case; but, on the other hand, surgical interference might not, and most probably would not, be called for. Under these circumstances, losing sight of the possibility of sutures being found other than in recognised localities might lead to errors in diagnosis. The consequences of such an error to an accused person might prove very serious to him in a court of law, as the Indian Penal Code makes the fracture of a bone "grievous hurt," whereas a scalp wound, uncomplicated, would come under the heading of "simple hurt." In normally placed sutures of course the above contingency would not be likely to occur.

In the case reported on the irregular sutures were found in the frontal and occipital regions—localities wherein scalp wounds from the *lathi* are very common in this district, as also are head injuries from the same weapon.

A CASE OF PLAGUE WITH MULTIPLE BUBOES: RECOVERY.

BY COOVERJI RUSTOMJI AVARI, C.M.S.,

Hospital Assistant, Railway Medical Inspection Duty,
Dhond.

BHIKI ROWJI, a girl, aged 7 years, travelling from Poona, was detained at 7-30 P.M. on the 28th October last at the Dhond Plague Camp on account of fever.

Condition.—Temperature 102°: no buboes: staggering gait: an indefinable fear and timidity: sordes on teeth and lips: tongue furred thickly brown: bowels not moved for two days.

Treatment.—In consultation with Assistant Surgeon J. KNOX THOMAS, two grains of calomel with an equal quantity of sodii bicarb were given, immediately followed at 10-30 P.M. by a soap and water enema, which produced a copious stool: temperature at that hour 104.4: four buboes now developed—one in each axilla, and one on either side of neck: those in axillæ were treated with belladonna and glycerine, and those on the neck with equal parts of tincture and liniment iodi: the following mixture—

Liq. Ammon. Acet.	℥iv.
Spt. Etheris Nit.	℥i.
Spt. Ammon. Arom.	℥ 40.
Tinct. Nucis Vom.	℥ss.
Tinct. Digitalis.	℥ss.
Rum	℥vi.
Aquæ	ad ℥iv.

one-eighth part every two hours was prescribed, and absolute rest and quiet insisted on.

27th October.—Unconscious, restless, with low muttering delirium: pulse intermittent: temperature 104.6: all four buboes well defined and very tender and painful.

Treatment.—Two minims each of liq. strychnia and tinct. digitalis with 20 minims of rum given hypodermically, after which pulse improved slightly: this was repeated in an hour: fomentations ordered to buboes, and rest of treatment continued.

9 p.m.—Temperature 102.6: vomiting and pains in abdomen relieved by two mustard plasters at an interval of an hour: owing to inability to swallow on account of weakness, nutrient enemata ordered: condition very prostrate.

28th October.—Two more buboes, one in each groin, developed: temperature 105°: pulse intermittent and flickering. Strychnine, digitalis and rum hypodermically injected and repeated, first in half an hour, and then at increasing intervals for six times. In the evening,

after anaesthetising the parts with cocaine, 15 minims of liquor hydrarg. perchloridi were injected about half an inch below each of the groin buboes, and one-eighth gr. of morphia injected hypodermically at bed-time produced good sleep.

29th October: 4-30 a.m.—Temperature 104.4: very prostrate: cold sponging all over body and liniment iodi over all the buboes.

9 a.m.—Temperature 101.6: buboes in axillæ attained large size: antiseptic poultices applied every hour: other treatment continued: in the evening patient appeared brighter, and for the next two days the temperature kept below to 102.2.

1st November.—Temperature 101.4: mind clearer and every way now a hopeful case: owing to folly of father raising her from the bed, the little patient fainted and nearly succumbed: being close at hand at the moment, hypodermic injections as before with mustard plaster over the cardiac region restored her. The groin and neck buboes seemed now to be subsiding, but the temperature in the evening rose to 102.4: morphia given hypodermically to procure sleep.

2nd November.—Axillæ buboes found fluctuating, and after repeated poulticing were opened on the following morning with all aseptic precautions, yielding 6 ounces of pus each: dressings—iodoform and boric acid: temperature fell to 100.4.

4th November.—Temperature 100°: two large cavities in each axillæ washed out with lotio hydrarg. perchloride (1 in 800) and dressed again with iodoform and boric acid.

6th November.—Temperature normal: diaphoretica stopped, and the following mixture given for four days:—

Quin. Sulph	grs. 20.
Acid. Nitro-muriatic Dil	℥ 30.
Liq. Strychnia	℥ 15.
Tinct. Digitalis	℥ 20.
Syrup	℥iv.
Aquæ	℥iv.

One-eighth part thrice daily after meals: diet—milk, mutton broth, eggs and occasionally stimulants. After this improvement was rapid. A tonic of iron, quinine, strychnine and nitro-muriatic acid was then prescribed, and the little patient discharged on the 26th November, the neck and groin buboes having subsided.

Pleurisy.

DROPSY—that is to say, anasarca and ascites—sometimes occurs even in acute pleurisy with effusion on one side only, there being no sign of nephritis or of disease of the heart, and the patient recovering completely in about three months. In such cases the dropsy must be due to stagnation of the blood in the right side of the heart.—Dr. GEE, Allbutt's "System of Medicine."—*New York Med. Rec.*

Indian Medical Record.

2nd January 1901.

THE SEVENTH ANNUAL GENERAL MEETING OF THE INDIAN MEDICAL ASSOCIATION.

In accordance with the notification duly given in the *Indian Medical Record* of the 26th December 1900, the Seventh Annual General Meeting of the Indian Medical Association was held at the Office and Library of the Association, 50, Park Street, Calcutta, on Friday, the 28th December 1900, at 6 P. M., when there was a fair attendance of members and visitors.

Telegrams from the representatives of the Association in various parts of the country were received, in which the Council was congratulated upon its labours, and earnest wishes were expressed for a prosperous new year. Dr. Lal Madhab Mookerjee, Rai Bahadur, President of the Association, was voted to the Chair.

After a few words of welcome to those present, he called upon the Secretary to read the—

SEVENTH ANNUAL REPORT OF THE INDIAN MEDICAL ASSOCIATION.

The Secretary has the honor to submit the following report of the affairs of the Indian Medical Association for the year 1900 :—

Membership.—While there has been no withdrawal from our Society, death has claimed three of our number during the year 1900.

It is gratifying to note that the list of members has been augmented during the year, and may be classified as follows :—

	1894.	1895.	1896.	1897.	1898.	1899.	1900.
Army Surgeons ...	2	14	57	55	58	58	58
Independent Physicians ...	71	105	123	157	160	163	167
Civil Surgeons ...	72	94	102	111	124	128	128
Civil Assistant Surgeons ...	79	95	122	135	155	166	170
Military Assistant Surgeons ...	173	194	260	318	328	333	336
Hospital Assistants	49	85	87	132	326	339	342
Total	446	587	751	908	1,151	1,187	1,201

THE COUNCIL AND ITS WORK.

OFFICERS AND COUNCIL.

President:—Lal Madhab Mookerjee, Rai Bahadur, L.M.S., F.C.U., Principal, Calcutta Medical School.

Vice-Presidents:—(1) H. H. Sir Bhagvat Sinha, G.C.I.E., M.D., C.M., F.R.C.P., Edin., LL.D., D.C.L., Edin., Thakore Sahib of Gondal, Kathiawar. (2) E. W. Chambers, L.M.S., Cal., L.S.A., London.

Members of Council.—Representing Bengal and resident in Calcutta (4 members) :—

1. H. W. Jones, M.D., M.R.C.S., Eng.
2. J. E. Panioty, L.R.C.P. and S., Edin.
3. R. G. Kar, L.R.C.P. and S., Edin.
4. Rakhal Das Ghose, L.M.S.

Representing—

5. *Bombay.*—Alfred McCabe Dallas, L.M., Dub., L.R.C.P.I.
 6. *Madras.*—C. G. B. Naylor, M.R.C.S., L.R.C.P., Lond.
 7. *Central Provinces.*—Mirza Kerim Khan, M.B., C.M., Edin., Hyderabad.

Bankers.—Messrs. Grindlay & Co., Calcutta.

Two members of Council, Drs. Anderson and Sirkar, resigned since last annual report, and in their places were elected Drs. Panioty and Kar respectively.

Meetings of the Council.—The Council held three meetings during the year. Six others were called, but failed for want of a quorum.

Work of Council.—The three recorded meetings were well attended. Much of the time at each meeting was occupied with the developing of the Association Provident Fund, as the reports in the appendix plainly prove. The question of Indian medical college appointments has been forcibly brought to public attention in England by our Journal and by our representative in London (Dr. S. Mullick), who has succeeded in inducing the British Medical Association to appoint a Committee to enquire into the subject. The question of appointing civil medical practitioners in Calcutta to the Native Mayo Hospital has been taken up by the Council, and it is hoped that a favorable issue may result therefrom. The Council has also moved the Government for the opening of a professorship in Throat and Ear Diseases in the Calcutta Medical College. Several instances of individual grievances among members of the Association have been represented to Government, in three of which satisfactory results have been obtained.

It only remains to invite all members of the Association to exercise their best endeavours to promote the growth of the Association by further additions to its membership, for by unity alone can strength and progress result.

PRESIDENT'S SPEECH.

AT the close of the above Report, the President addressed the meeting as follows:—

LADIES AND GENTLEMEN—

It is a great pleasure to me to preside at this annual meeting of our members. Our Association is now seven years old, and it is with some degree of pride and satisfaction that I acknowledge the honor of having presided at seven of the annual meetings, and to have taken an active part in all the deliberations of the Council of our Association since its inauguration in 1894. I think we may congratulate ourselves as a Society on two important points—one is our steady growth, and the other is the activity and the scope of our operations. No task for the improvement of the local medical profession has been considered too great, nor has any interest, no matter how trifling in its concern for the humblest member of our Association, escaped our attention. It is a source of gratification, therefore, to be able to say that the governing body of our Society have, each and all of them, done their duty right manfully and well. Our Secretary, in his report for the year that is now closing, has briefly sketched the nature of our work during the past twelve-month. We are all busy men on the Council, each one burdened with his professional and domestic cares, yet we have found time for carrying on the labors of the Council, and I think it will be admitted that the efforts of the past seven years have been attended with a fair measure of success all along the line. My purpose this evening is to point out the means by which a still larger measure of success and prosperity will attend not only our members individually, but enhance the status of our profession and of our Association. We need to add numerically to the membership of our Association, and we require also to enhance the status of our members. In a country like India, the profession of medicine has much to hinder its progress and to retard its growth and use-

fulness. It is no exaggeration to say that our universities have turned out upon the public at least 20,000 fully qualified medical practitioners, while the smaller medical schools have probably doubled this outturn with a lower grade of practitioners, so that we have from fifty to sixty thousand qualified men in India, of two distinct grades. In this great city alone, we have at least four to five thousand practitioners of these different grades. Considering these vast numbers, does it not seem disparaging that the important work of this Association has not attracted more sympathisers and more active supporters to its standard? Does it not betray a discreditable apathy on the part of the local medical profession, when it is found that our Association has not yet completed a membership roll of 2,000? It has been suggested that we should employ canvassing agents touring the country in order to win them into our fold. Of course we cannot do this. Great publicity is given to our cause by the weekly publication of the *Indian Medical Record*, which now has a circulation of 2,000 copies all over the Indian Empire. Surely such publicity ought to suffice to attract even the most callous and the most apathetic. In this matter of increasing the popularity of our Association, each member has a distinct duty to perform, and were this done cheerfully and persistently during the coming year, we could more than double our membership in a twelve-month. An incident during this year's experience should bring this duty of increasing our membership very prominently and pointedly to the hearts and minds of Military and Civil Assistant Surgeons and Military and Civil Hospital Assistants. It will be remembered that recently, when the Council desired to approach the Government of India with a memorial regarding the grievances and disabilities of Military Assistant Surgeons, it was found that this could not be done, unless two-thirds of their body were members of the Association. We gave them a very clear hint at the time that more of them should join us, but this invitation has up to the present met only with a very faint-hearted

response. We want at least 300 more Military Assistant Surgeons, 200 Civil Assistant Surgeons, 200 Military Hospital Assistants, and 200 Civil Hospital Assistants to enter the Association before any of these services will possess the privilege of holding a representative position towards Government.

The Council, you may be sure, is not only quite able to voice the needs of each of these services, but it is quite willing to be their mouthpiece and representative. Yet you see now that a certain legal barrier has been placed in the way, and we cannot approach the Government unless a service has two-thirds of the strength of its membership on our rolls. The removal of this barrier lies in your own hands, and it remains for you to render the Association both active and powerful by becoming its supporters and adherents.

The next matter that demands our serious attention is the improvement of the status of the local profession. There must be ambition to rise in our sphere of life, and to acquit ourselves honorably in that sphere in which God has placed us. Let each member of our profession, rich or poor, reckon the honor of our common profession as being very dear to him. Let each be filled with noble aspirations, adopting every legitimate means not only to improve the mind by education and wide study, but in attaining the many high honors and distinctions that are open to medical men. The Universities and Corporations of Great Britain and Ireland, as also those of the Continents of Europe and America, offer degrees and qualifications of the highest value and repute. Recently a nefarious trade in bogus and discreditable American diplomas, base and worthless, has sprung up in India, and many of the lower orders of our brethren have taken advantage of this dishonoring traffic, and have bought for money high-sounding, but false and worthless, titles. Their transactions are not only fraudulent, but criminal, and it is to be hoped that complete exposure and punishment awaits them all. I believe in the Biblical injunction, which says that "man shall eat bread by the sweat of his brow." We readily honor talent and industry, for the noble insignia of science cannot be purchased with dross. Nothing would raise the status of our Association more than the possession by its members of the higher degrees and honors obtainable by diligence and perseverance, in this land and in other lands. It is a notable, but regrettable, fact that graduates of Indian Universities do not aspire to the degree of M. D. which our Universities are willing enough to give them, if they will work up for it. They seem to be perfectly satisfied with the lesser degrees of L. M. S. and M. B. I, for one, do not consider the M. D. degree of an Indian University less difficult to obtain than the same degree of a British University. An Indian M. D. is indeed a very high distinction, and it would greatly enhance the status of the local profession were the possessors of this degree more common than they are at present. It is a far easier matter to obtain the diplomas of the British Corporations than it is to obtain the lesser Indian degrees. Yet the former possess a higher value, simply because they are British. I would be glad to see the status of our brethren of the Hospital Assistant class improved. They now undergo a very fair curriculum of four years' medical study, and I think they ought to be

provided with a distinct diploma. This step would be a source of gratification to them, and it would cost the Government nothing to grant the favour. You will remember that a little while ago the Council approached the Government of India on the subject of systematising the medical studies and the diplomas granted to the various grades of practitioners who pass through our colleges and schools. It is quite possible that some day this important matter may find some Director-General of the I. M. S. sufficiently interested in the subject to place it on an equitable basis. We anticipated much help in this matter from Surgeon-General Robert Harvey, C.B., the present Director-General, and it is possible that something may yet be done before he gives up the reins of his important and difficult office.

I thank you Ladies and Gentlemen heartily for your kind attention to my brief address, and I trust that each and all of us will do our part in advancing the highest and best interests of our Association and of our profession. I take this opportunity also of thanking my colleagues in the Council for their valuable help at our meetings, and my thanks, and the thanks of all of us, are due to our worthy Secretary, the Editor of the *Indian Medical Record*, for his ever ready co-operation in the advancement of our cause. I now wish you all, most cordially, a bright, happy and prosperous New Year (applause).

The following resolutions were duly proposed, seconded and carried :—

1. *Resolved* that the Annual Report for 1900 as read by the Secretary be adopted.
2. *Resolved* that the Council and the Association accept, with much regret, the resignation by Dr. K. G. SARCAR of his position as Member of Council, and they desire to record their sincere appreciation of, and thankfulness for, Dr. SARCAR's valued labors in the Council.
3. *Resolved* that the vacancy in the Council caused by the retirement of Dr. K. G. SARCAR be filled by Dr. R. G. KAR.

Heartly votes of thanks were given to the Chairman and to the Secretary for their labors.

THE TRAINING OF BODY AND MIND FOR THE PROFESSION OF MEDICINE.

SIR JOHN WILLIAMS, Bart., M. D., F. R. C. P., London, delivered, at the commencement of the winter session of the Faculty of Medicine of the University College of South Wales on October 10th last, an eminently practical address on the training, physical and mental, necessary for success in the ranks of the medical profession. We endeavour an epitomé from a report in the columns of the *British Medical Journal*. The speaker warned the students that the path to success in this profession was in no way a bed of roses. It necessitated a careful preliminary training, hard study, and later hard work. The treatment of the profession and the estimate of its work by the public were often unjust, and this was scarcely to be wondered at, considering the usual education im-

parted in schools and universities. Ignorance prevailed with regard to the very elementary laws which governed man's life and actions. This was the case generally in the upper as well as in the lower classes of society, and ignorance and superstition in respect of medicine, of the power of drugs, and of the skill of medical men, were as prevalent among the educated as amongst the uneducated. Attention was then called to the prevalence of quack medicines supported by quack advertisements in newspapers, which professed to teach and lead the public and to form public opinion—an unwarrantable sanction by silence, or speech, or writing, by all concerned in the publication of such journals. The fact that religious papers were as culpable as secular brought a blush of shame to the cheeks of the speaker, when he remembered under whose aegis they were published. What was the remedy? A more practical education. Let the elements of science, the laws of growth and decay, and the laws regulating the functions of the living body, be taught in the schools, and young men and women would themselves be able to estimate this mephitic rubbish at its proper value. Nevertheless the medical profession was a noble and ennobling one. True, the work was on the dark side of life, but this only enlarged and widened sympathies, whetted wit, and increased one's resources. Dealing with the qualities necessary for success in the profession, the speaker referred particularly: (1) To a sane mind in a healthy body: success in medicine meant survivorship, and survivorship usually meant a good physique, and although health was inherited, much could be done to strengthen a weak constitution, especially during the period of childhood, boyhood and early manhood, by moderate diet and an active out-door life with sufficiency of physical exercise. (2) To training the senses. The training could not be begun too early. All boys should be trained to use their eyes, ears and hands and to acquire manual dexterity. The faculty of observation was one of the chief aids to a medical man, and its cultivation could not be begun too early. In connection with the sense of hearing, singing was taught in most schools; but drawing, with some amount of handicraft, might also be taught with advantage. By training the hands a manual dexterity with a delicate sense of touch capable of appreciating slight vibrations and slight differences of resistance and elasticity were acquired, all of which were of the greatest value to the practitioner in the diagnosis and treatment of disease. Training of the eyes and hands were as essential to a medical man as it was to an artist, and training of the ears and hands, was as necessary to him as it was to a violinist or pianist. On the subject of a classical education as a preparation for professional training, the speaker remarked that it was important that a boy preparing for the study of medicine should receive the best attainable culture and training. The solution of this, made long ago and partially acted upon now, was a classical training. The matter, however, required reconsideration in the altered state of medical knowledge. Sir JOHN had not a word to say against classical scholarship; but there was much to be said upon the question whether a boy preparing for the medical profession should

devote several years to acquire a knowledge—invariably smattering—of such subjects as Latin and Greek. Though the surpassing excellence of ancient literature was indubitable, it could not be denied that in the English, French and German languages there was a sufficiency of good literature to give a high kind of enjoyment and to cultivate very adequately the literary taste. In this aspect, it was perhaps worth even the medical man's while to devote the time to learn Latin and Greek; but classical literature, in spite of its enormous prestige, had very little attraction for the mass of even cultivated persons at the present day. Its cultivation from a practical point of view, for the medical profession, was useless. The greater part of six or seven years devoted to gain such an accomplishment appeared to be wholly wasted. What then should a boy destined for medicine learn before he began his special studies at the age of 17 or 18 years? In addition to those subjects usually taught in schools, he should have a thorough course of the English language and literature: this would do more to train his intellectual faculties and give him a command of language, a taste for good literature, and a culture far larger and better than he could obtain by acquiring an elementary knowledge of Latin, which would be of no use, was too scrappy and soon forgotten. French and German should also be learned, for the speaker believed that the power of reading both languages with ease could be acquired in the time now devoted to Latin and Greek, and that a knowledge of those two languages was essential to a practitioner who was desirous of being among the leaders of his profession, for the work done in the laboratories and hospitals of France and of Germany was of such a high order that no one who was ignorant of it could be considered abreast of medical knowledge. Sir JOHN then, speaking to a Welsh audience, referred to the encouragement given to the study of Welsh, a living language still, and advocated its study by those in Welsh universities. While these elementary subjects were imbibed, some time should also be given to gaining a familiarity with the elements of the natural sciences: so that, when college was entered, the subjects would not be strange which bore directly upon the medical profession. An elementary knowledge was therefore necessary of the principles of physics, chemistry and biology, together with a grasp of the general character and methods of all sciences. If the student had availed himself of the opportunities of learning offered during the first three years of his collegiate career, he would find his knowledge of disease and his skill in detecting its seat and nature grow apace. On the completion of the curriculum, Sir JOHN strongly advocated the necessity for holding a resident post of house physician, house surgeon, or resident obstetric officer, either one or all. Such a post would give in a few months an amount and kind of experience that private practice would not furnish. Further, the speaker advised cultivation of independence of character and freedom of thought. The two generally went together, and both were essential in the practice of the medical profession, both for the comfort of the physician and the good of the patients. And lastly, cultivation of sympathy was advocated: not a sentimental sympathy, but a sympathy aroused only by the real of distress, to which its response was never wanting, and when so aroused, it was always to some purpose.

COMMENTS AND NEWS.

PROTECTION AGAINST MALARIA.

EXPERIMENTS under the direction of Professor GRASSI have been carried out at Paestum with a twofold object: (1) To prove conclusively that malaria can be transmitted only by the bites of *Anopheles*; (2) to overcome the difficulties of the practical application of this discovery, and to decide on the means to be taken to rid Italy of malaria. Paestum was chosen on account of the special prevalence of the disease there. Here, during the malaria season, most of the inhabitants either leave or spend their night on the surrounding hills; a certain number, for example the railway officials, have to remain, and it was determined to use these for the attempt at protection. In the first place all those who showed any trace of malaria during the healthy season (January to June) were treated with quinine; and secondly, all under observation were protected from the bites of mosquitoes by nets during the infective period. The first infected mosquito was found on June 14th, and, allowing twelve days' incubation, malaria was anticipated on the 26th; as a matter of fact, the first case occurred on that date outside the zone of experiments. Three cases of relapse occurred during the infective season in persons who had falsely asserted that they had not previously had the disease. The preventive rules laid down were: to keep within the protected dwellings from sunset to sunrise, and in the case of officials who had duties during this time, to wear light veils and thick cotton gloves. The houses were protected everywhere, even the chimneys, with wire netting. Here and there an *anopheles* was found in the houses, but they were for the most part caught before they had stung any one. All the persons under observation were visited twice a day; precautions were taken against their procuring any quinine, and yet all continued free from malaria. The number was 104. In the country surrounding the protected zone, on the other hand, the disease was general, and affected by far the majority of the inhabitants, even when living on farms in high situations. The twofold object of the experiment was therefore attained, and the practical protection from the bites of *anopheles* shown to be feasible.

THE PRACTITIONER'S DUTY IN THE TREATMENT OF ACUTE INTESTINAL OBSTRUCTION.

The practitioner's duty in the treatment of acute intestinal obstruction is summarised by MAYLARD (*the Practitioner*). He says there are no cases which occur in general practice that present greater difficulties in diagnosis than the subject here treated. Various symptoms and signs are enumerated, which he says might easily apply to one of many intra-abdominal disorders. He says, however, that the general practitioner can in almost all cases determine when there is "peritonism," whatever may be its cause. This being determined, there remains but one thing to do—open the abdomen. It is necessary that operation be done early to prevent disastrous consequences, not only from the lesion, but from the absorption of toxins. When acute obstruction occurs, the general practitioner should inject cocaine and open the abdominal cavity, bring the intestine into the opening, and form an artificial anus which will relieve the condition temporarily. If need be, a general surgeon can deal with the trouble later. The author suggests, however, that gastric or intestinal perforation presents a very different problem. But even here the general practitioner should operate if the surgeon cannot be had on short notice, for delay means certain death. MAYLARD has devised a portable operating table, which is

especially suitable for the practitioner not connected with a hospital. If the condition has passed beyond the initial stage and vomiting has supervened, the stomach and large bowel should be thoroughly washed out and a nutrient enema given before operation. MAYLARD believes in opening the gut and drawing it up the pent-up contents before seeking for the obstruction. In case of perforation, whether the abdominal cavity shall be flushed out or merely wiped out, depends on the general or local education. If in doubt, flush out thoroughly. Before closing the bowel an injection of MgSO in solution directly into the bowel-lumen acts well.

WHAT IS OLD AGE?

DR. H. C. WOOD, M.D., of Philadelphia, writing to the *Philadelphia Medical Journal*, says:—

Old age is certainly not a disease, and scientifically should never be given as the cause of death. The individual really dies of senile atheroma, or senile nephritis, or senile something else. On the other hand, the theory that old age is connected with a definite number of years is incorrect. Nearly 40 years' experience in the practice of medicine has very firmly convinced me that as the human race has a general period, after which tissue-changes take place, resulting in "death from old age," so do not only individuals but families have an allotted time. There are men whose tissues are not as senile when they are 80 years of age as others are at 70, or others at 60, or even at 50 or 40. I have seen the almost complete extinction of two generations of certain families by the death from senility of the various members when between 30 and 40 years of age; as the deaths in these cases were the result of changes in the tissues, commonly called "senile," it is just as correct to say that the subjects died of old age, though they were perhaps only 35 years old, as it is to say that certain other persons have died of old age at 75 years of age.

It would be of no improvement in our death certificates to limit death from old age to a certain period of existence. If there is to be any change from the present plan, it should be the abolition of old age as a recognized cause of death, and the requiring that the death certificate should show that the subject died of senile atheroma or whatever was the cause of the taking off.

It seems to me a matter of very grave importance for the purposes of prognosis and practical treatment that the medical practitioner should recognize that old age may commence at any time of life. Some of the so-called cases of neurasthenia are in fact only instances of premature senility; hence their hopelessness.

A LADY DOCTOR'S DOUBLE VICTORY.

A FRENCH law court has lately had before it a case presenting some features of special interest to medical practitioners. A lady who holds the degree of Doctor of Medicine of the Faculty of Paris some time ago operated on a young child for abscess of the neck. The operation was successful, but the father declined to pay the bill, which amounted to 400 francs. The lady brought an action, and the defence was that the operation had been badly done, and that the treatment had done more harm than good. These allegations were supported by a certificate from a dentist. The Court, finding its unaided intelligence unequal to the settlement of the dispute, called in the assistance of Professor BROUARD, who is the principal authority on medico-legal matters in France. The eminent Dean of the Faculty of Medicine after a careful inquiry, gave it as his opinion that the operation had been perfectly successful, and that the treatment had been thoroughly satisfactory. The lady, encouraged by

this opinion, straightway brought a further action for damages, on the ground that the defendant had sought to justify his refusal to pay by misrepresentations calculated to injure her in her professional capacity. The Court heard the case argued at full length, because the point, though reasonable, was held to be new, and finally decided in the lady's favour on both counts. The ungrateful parent had therefore not only to pay the bill for attendance, but 50 francs in addition as a solatium to the wounded professional feelings of the lady doctor.

SIR MACKWORTH YOUNG ON BOGUS DEGREES.

WE quote from the *Statesman* :—At the annual distribution of prizes of the Lahore Medical College, the Lieutenant-Governor, in the course of a speech to the students, said :—“I am sorry to say that of late certain unscrupulous persons, for their own purposes, have been initiating traffic in educational degrees and diplomas, which have actually been sold for money in this country. Some years ago we were all very much shocked to learn that in one of the important countries of the European continent titles, honours, and rank had been made available for purchase at money prices. I am sorry now to have to state that medical degrees and diplomas have actually been bought and sold in India, and the initiators of this nefarious traffic have been found to hail from one of the States of America, and I grieve to say that there have been young men in India foolish enough and unprincipled enough to fall victims to their wiles. Of course those young men who have thus attempted to benefit by the supposed opportunity of obtaining medical diplomas by the mere expenditure of a little money are now holders of nothing more than pieces of waste paper; but you will be glad to hear from me, and I am able to announce the fact on the authority of the Government of India itself, that the principal agent of these conferrers of bogus degrees has been arrested and is now being held at heavy bail. There is, therefore, every prospect of this traffic being checked, and I take this special opportunity, having, indeed, been desired by the Government of India to utilise the earliest convenient occasion to warn you that there are these spurious degrees being offered for sale by foreign agents in this country, and to impress upon any of you who may be approached in the matter that the only honest and sensible thing to do is to abstain from spending your money on a thing which has absolutely no value.”

ORIGIN OF LEPROSY IN HAWAII.

THE *Journal of the American Medical Association* says:—The introduction of leprosy in Hawaii, from recent statements, seems to have been under the special protection of the native royalty and aristocracy. It first appeared in the person of a chief KAKAUNOHU, who had been to China, and from him was transmitted to another Naea, who was closely related to the reigning family. From the latter it quickly spread to his tenants and retainers, and for a considerable time was known among the natives as the

“ma'i aili,” or the chief's, or royal, disease. The missionary physicians soon learned to recognise it, and one of them, Dr. DWIGHT BALDWIN, it is said, made a report on it, stating the facts of its origin, etc., and filed it with the Minister of the Interior; but it was held from publication, doubtless on account of the connection of royalty with the introduction of the disease. So long as the Hawaiian monarchy existed, segregation of lepers, though legally demanded, was very imperfectly carried out, owing, it is said, to the interference in high places. Since the overthrow of the monarchy, however, the measures have been more effective, and the seeing of lepers on the streets, which was formerly an occasional event, is no longer possible. The isolation law is an unpopular one with the native Hawaiians, who possibly regret the passing of the old régime on that account as much as on many others. These data are obtained from the *Honolulu Commercial Advertiser*, whose authority for the main facts is the Rev. SERENO BISHOP, who was one of the earliest to recognise the affection on the islands. We have not seen this bit of medical history narrated elsewhere.

REMARKABLE DISPLAY OF NERVE.

ONE of the most remarkable displays of nerve and will-power ever witnessed at any of the Reading hospitals was that reported of ALLEN WOLFESKILL, the young man who had both of his legs crushed in attempting to jump from a moving freight train on the Reading Railway. In speaking of the accident, he said : “The moment I dropped to the tracks, I felt the wheels passing over my limbs, and that they were gone. I did not faint; but realizing the fact that I would bleed to death unless something was done quickly, I set to work with a view of stopping the flow. I first tied up my right leg with my handkerchief, and while I was doing this a companion who had been more successful in jumping the train than myself came along and let me have his handkerchief, and with this I bound up the left limb.” He urged the driver to hurry while on the way to the hospital, and said if he did not he would take the reins himself. He did not want ether administered, so that he might witness the amputation.

ELECTRIC APPLIANCES IN CALCUTTA.

Indian Engineering says:—The popularity of electric appliances in Calcutta has in a very short space of time assumed vast proportions, and it is hardly too much to say that electricity has now become a very important factor in the domestic economy of the citizens. There is no private house of any pretension but has its electric installation for lighting and punkas, and it is a very insignificant public place that is not so fitted. Calcutta has certainly taken the lead in this matter among all the cities of Asia.

TEST OF KHAKI COLORS.

AN interesting and important test is in progress at Fort Myer, Va. Some complaints have been received at the War Department that the shade of garment known as khaki color offers more of a target than blue, which was the color of the former shirts issued by the quartermaster's department. The test at Fort Myer is for the purpose of ascertaining the relative protection offered by the two colors. The tests include observations of garments of different colors at various distances.

SHORT ITEMS AND PERSONALITIES.

Miss M. Trail-Christie, M.B., has been selected for the permanent charge of the Victoria Dufferin Hospital in Calcutta. Miss Christie is a lady possessing the highest qualifications, and was somewhat lately on plague duty in India. She has held several important posts at home, and will come out in February. The competition for the post in Calcutta was, we hear, very keen.

Lieutenant-Colonel B. D. Murray, I.M.S., "Professor" of Surgery to the Calcutta Medical College, has withdrawn his subscription from the *Record* owing to our remarks on his "Stone" case. We fear this serious monetary loss is likely to cripple the very existence of the *Record*! Will somebody kindly *apologise* for us?

Miss Holman, the lady apothecary, has been appointed Resident Assistant Surgeon to the Lady Curzon Hospital, Bangalore, on a salary of Rs. 120 per mensem and Rs. 50 for an allowance charge. Miss Holman takes charge on the 5th proximo.

Lieutenant-Colonel J. Maitland, I. M. S., has returned to Madras after a year's furlough and taken charge of Senior Surgeon's Office in the General Hospital, Madras, from Captain Giffard, who was acting for him. Captain Giffard goes to Trichinopoly as District Medical and Sanitary Officer."

Lieutenant-Colonel Hatch, I.M.S., and Lieutenant-Colonel Channer, I. M. S. (Bombay), have been selected for appointments on the administrative grade."

The number of Military Assistant Surgeons and Hospital Assistants to be entertained in each Command is now under the consideration of the Government of India.

Craving for whiskey is overcome by dropping a few drops of tincture of cinchona far back on the tongue.

WANTED—A THIRD GRADE HOSPITAL ASSISTANT to come to Burma on mutual transfer with the undersigned. Any one from Punjab or N.W. P. will be accepted. For particulars, address :—

H. A.,

C/o Manager, "Indian Medical Record."

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE INDIAN MEDICAL RECORD will, upon publication, be liberally paid for, or 250 copies will be furnished instead of payment. When necessary, to elucidate the text, illustrations will be provided without cost to the authors. Address the Editor, JAMES R. WALLACE, M.D., F.R.C.S., 50, PARK STREET, CALCUTTA.

NOTICE.

All members of the Indian Medical Association are kindly requested to send their names in full with their present addresses, clearly written, to the Secretary.

Members who have paid their subscriptions and who have not received the membership certificates are kindly requested to notify the same to the Secretary.

Subscribers are requested to communicate any temporary change of address not to the Office of this Journal, but to the post-office through which they are accustomed to receive their Journals.

The Indian Medical Association fights the battles of the Medical Profession as a whole, and it takes up the cause of individual members as well. Join the Association and you will not be disappointed.

Medical Appointments, Transfers, Exchanges are easily and cheaply effected through our special short advertisement page. See terms and apply at once.

The *Indian Medical Record* offers the following prizes :—Rs. 10 to Rs. 16 for a good Original Article ; Rs. 5 to Rs. 10 for a good Clinical Report. Competitors must be subscribers to the *Record*.

Members of the Indian Medical Association will kindly note that while the entrance fee to the Association is fixed at Rs. 5, the annual subscription is reduced to Rs. 2.

The Indian Medical Association Provident Fund is now working. It offers a simple and safe form of Life Assurance to all medical men and women. Join at once.

News items of medical interest from all parts of the Indian Empire are asked for by the Editor for publication in the *Record*.

Current Medical Literature.

MEDICINE.

Treatment of Ataxic Patients by Co-ordination Exercises, with Demonstration of Two Patients.

JAMES J. PUTNAM says that in the treatment by this method several points should be strictly borne in mind: (1) It is skill, not strength, that it is sought to develop. (2) It is necessary to begin with relatively elementary motions, such as drawing the leg up and down in bed, or moving the finger from one spot to another. The patient should be called upon to perform them with promptness and accuracy and at the word of command. (3) Dulness, monotony, and fatigue, on the one hand, and superficiality on the other, are the rocks to be avoided, both by the introduction of sufficient variety into the exercises, and by giving them something of the entertainment of games of skill. (4) It is not well to let the patient get on without an instructor, using a prescribed set of exercises. The necessity for obedience to the word of command, which calls for close attention and for movements which come to have something of the character of involuntary reflexes, is a great help in stimulating both the conscious and the sub-conscious attention and the power of instinctive control. (5) Weak, anæmic patients, and those suffering constantly from pains and crises, those with atrophy, rupture of tendons, cardiopathy, aneurism, obesity, arthritis, laxity of ligaments, or severe arthropathy are not good subjects for the treatment. —*Boston Medical and Surgical Journal.*

Gravity of Rheumatism in the Child, from the Point of View of Cardiac Complications.

M. H. BARRIER declares that articular rheumatism in children is an affection of grave import on account of the frequency and severity of the cardiac lesions incident thereto. Various authorities state the percentage of cardiac affections to be eighty-one per cent., or even as high as eighty-seven per cent. The onset of rheumatism is often marked by general phenomena—fever, headache, vomiting, etc.—which show that in children rheumatism has more the course of a general infectious malady than that of a multiple arthropathy, and that the visceral localizations in the heart in particular are not in relation to the intensity of the articular manifestations. The majority of cases of rheumatism in children, which BARRIER has observed, accompanied by more or less grave cardiac complications, have yielded in a few days to treatment by sodium salicylate. Death may occur in from three to six months after the beginning of rheumatism in children previously in good health. It is probable that the severity of the cardiopathies in the child are mainly due to pericarditis. It causes in a great number of cases a fatal termination. —*Journal de Médecine de Paris.*

Albuminuria in Young Men.

H. W. SYERS claims that in the case of young men between the ages of fifteen and twenty or twenty-five years, albuminuria is often found which is not a symptom of renal disease. As albuminuria can be induced in perfectly healthy and robust individuals by exposure to cold, the author holds that many of these cases are due to chilling of the surface of the body, as in open-air bathing. Why albumin should appear more readily in the urine in some cases than in others in which the same exciting cause is present can be explained

only on the same principle as the well-known tendency of some people to catarrh on the least exposure. When examination shows entire absence of the renal heart (hypertrophy of the left ventricle, reduplication of the first or accentuation of the entire second sound), a pulse of normal tension, and no cedema or dyspnea, then, if there are no casts, it is in the highest degree probable that the kidneys are perfectly sound. Of course it is possible that if the patient is likely, from carelessness or necessity, to be repeatedly subjected to the chilling process, what is at first merely an ordinary stasis in the kidney might, by constant repetition, become a renal inflammation. —*The Clinical Jour.*

Significance of Oxaluria.

DR. ROBERT F. WILLIAMS, from a lengthy consideration of the subject, draws the following conclusions:—

1. Whereas the appearance of oxalates in the urine—excluding their ingestion in foods—is due to a derangement of digestion or metabolism, this derangement probably has its cause in many cases in functional nervous irregularity, which may or may not be so great as to produce general nervous symptoms, and if these are present, they are not necessarily caused by the oxalates.

2. The condition causing the appearance of oxalates in the urine may produce symptoms closely simulating the constitutional symptoms of BRIGHT'S disease.

3. The excretion of oxalates by the kidney for a short while may occasion no local disturbance of that organ, but if continued may, by irritation, cause the appearance of albumin and casts with lessened urine, corresponding to the urinary symptoms of BRIGHT'S disease, and if unchecked may lead to permanent destruction of kidney tissue and true BRIGHT'S disease.

4. In all suspicious cases in which the nephritic symptoms are accompanied by the appearance of oxalates in quantity, diagnosis should be held in abeyance and the oxaluria overcome by appropriate remedies to exclude this as a possible cause of the symptoms before making a positive diagnosis and pronouncing a necessarily hope-dispelling prognosis. —*New York Med. Rec.*

Infantile Stools.

THE following summary is appended to a paper contributed to the Physician and Surgeon by Dr. CHARLES DOUGLAS:—

Green stools are never healthy.

They always show imperfect digestion.

The damage to the child is in direct proportion to their presence.

These stools render children more susceptible to acute gastro-enteritis in hot weather.

The high infantile summer mortality follows children suffering from this colored stool.

Through unhealthy nutrition the blood is poisoned and the various tissues are improperly nourished.

The excreting organs, particularly the kidneys and liver, are frequently damaged by the extraordinary duties imposed on them in the elimination of these poisonous results from the blood.

The continued irritation and innutrition favors the development of inherited diatheses and acquired cachexias.

No child is free from complications dangerous to life, or from developmental errors, who suffers from frequently recurring green colored stools, particularly the very liquid and foul smelling ones. —*New York Med. Rec.*

SURGERY.**What Fractures are Amenable to Immediate Massage?**

LUCAS-CHAMPIONNIERE says:—The term gluco-kinesis has been coined by CHAMPIONNIERE to express his methods of gentle massage without causing pain, applied as soon as possible after the injury that caused the fracture, with no attempt at immobilization. The repair of the bone and absorption of fluids is much more rapid and complete than with other methods of treatment. The vitality of the parts, suppleness and nutrition are maintained, while the pain and contraction rapidly disappear. The fractures that always benefit by this treatment are those of the upper portion of the humerus to the insertion of the deltoid, and of the lower portion to four finger widths from the joint; all fractures of the malleoli with no tendency to displacement sideward or backward; all fractures of the elbow, and especially of the olecranon, all fractures of the radius at the wrist without too much retrodisplacement; nearly all of the clavicle; all of the lower portion of the fibula without a tendency to deviation from the axis of the foot; all fractures of the femur or tibia at the knee without displacement, and also all fractures of the scapula. Other fractures which exceptionally justify this method of treatment are those of the middle portion of the humerus and of the two bones of the leg without displacement, and fractures of the two bones of the forearm. In certain other cases massage and immediate mobilization can be combined with the use of an apparatus, but the results are less complete and remarkable than when no apparatus is used. In children, mobilization is sufficient without massage, and the latter is also omitted in the aged if the veins are dubious.—*Journal de Médecine de Paris*.

Case of Syphilitic Gummata of the Spinal Cord successfully treated by Enormous Doses of Iodide of Potash.

THIS case, reported by Dr. F. W. CAMPBELL, of Montreal, was a very interesting one. The patient was a highly neurotic individual, and some time before had suffered from insomnia of an aggravated character. Retention of urine and loss of power in the lower limbs were noted. The patellar reflex was about normal. The loss of power in the lower limbs was absolute. The pulse varied from 80 to 96; the temperature never above 99. The stomach remained in fairly good condition all the time. A consultant from New York was brought on, and a diagnosis was established of tumor of the spinal cord, situated about the first lumbar vertebra, which might be sarcomatous or syphilitic. The advice of the consultant was to give 500 grains of iodide of potash per day, at first commencing with a drachm three times a day. Dr. CAMPBELL recited the daily history of the patient while getting under the large dose and its gradual withdrawal. The patient is alive to-day and in good health, having recovered complete control of his lower extremities.—*The Practitioner*.

Treatment of Severe Cases of Diphtheria with Saline Infusions.

E. E. LASLETT states that in the acute stage saline infusions are employed to dilute the toxin by the introduction into the system of an additional amount of fluid which helps also to flush out the kidneys. In the late stage they are used when along with the persistent vomiting; nutrient enemata are also rejected. Inasmuch as the fluids of the

body are thus constantly diminished, the blood must become more viscid, and the action of the heart be impeded. Saline infusions tend to prevent this state of affairs. LASLETT used two teaspoonfuls of common salt to the pint of water, utilizing as a site of injection the loose skin below and outside of the right breast. Gravity was the force employed the bag being held about three feet up. He found that from ten to fifteen ounces can be injected in half an hour. The child does not seem to mind the operation at all. Fifteen cases are reported. The only safe conclusion drawn (seven died, but the type was severe,) is that the treatment seemed to have some influence in diminishing both the frequency of onset of symptoms of heart failure and their severity when they did occur.

Method of Hand Disinfection.

J. HAHN has used the following method with success, and believes it possesses advantages over those in general use. The hands and forearms are scrubbed with common yellow soap and water at a temperature of about 104° F. with a boiled brush, the water being changed four times, and sufficient soap used to make a lather. After the second scrubbing the nails are cleaned and trimmed. The washing is then continued for four minutes with an alcoholic one per cent. bichloride solution, which is rinsed off in a one to two per cent. aqueous solution of the same agent (for one to two minutes), and they are finally again immersed in the alcoholic solution after the operating-gown, has been put on.—*Centralblatt für Chirurgie*.

Recurrent Epididymitis.

AFTER a review of the subject and brief reports of a number of cases, CHETWOOD concludes as follows: (1) Surgical resection of the testicular ducts, which obliterates the lumen entirely and positively prevents an ascension of the spermatozoa into the urethra, also prohibits the descent of inflammation from the urethra into the epididymis. (2) The pathologic occlusion of the ducts by inflammatory process only accomplishes this result partially, since it is clearly in evidence that many of the cases having had double inflammatory epididymitis still continue to suffer from a recurrence of inflammatory attacks in the epididymis, and since it is also proved that some of these individuals continue to have vital spermatozoa in their seminal discharges and to retain the capacity to impregnate their wives. He is not aware that this point has been clearly demonstrated before this writing.

Etiological Significance of Trauma.

DIRSKA deprecates the tendency to attach undue importance to acute trauma as a cause for secondary illness, especially in cases in which suits for damages are involved. Traumatic neuroses are often diagnosed, but in the author's opinion are really comparative rarities. The possibility of the lighting up of otherwise latent tuberculous pneumonic or cancerous growths through somatic concussions is, to say the least, problematic. There are three fallacies that frequently stand sponsors for an erroneous diagnosis of a traumatic origin of a disease. First, the assumption that it is particularly the lighter forms of injury that are followed by such consequences; second, one is easily carried away by the plausibility of an ingenious theory, apparently correlating the supposed cause with the effect; and third, the factor of auto-suggestion is strong in the patient, and there is an almost universal tendency to connect illness with some previous injury.—*New York Med. Rec.*

OBSTETRICS AND GYNECOLOGY.

Management of Normal Labor, including the Use of Forceps;

DR. AUSTIN FLINT, JR., of New York City, urges that it be made a routine practice carefully to examine the pregnant woman at the end of the eighth month. This examination should, of course, include pelvic mensuration. The patient should be instructed to take daily walks up to the very time of labor, as this exercise would strengthen the muscles, soften the cervix, aid dilatation of the latter, and make abnormal presentations less frequent. At the time of labor the genitals should be sterilized, and an examination first internal and then external, made in order to confirm the results of that made the previous month. It was far better to make this one examination complete and thorough than to make a number of superficial examinations at short intervals. The practice of giving a little ether with each pain was gaining ground, the administration being conducted in just the same way as with chloroform. Emphasis was laid upon the importance of observing the old rule, to prevent, as long as possible, the rupture of the membranes. An anæsthetic was of great advantage in many cases, yet those who used anæsthetics most would probably see the largest number of cases requiring forceps. As soon as the head ceased to descend, and the withdrawal of the anæsthetic or stimulation failed to restore good uterine contractions, a low forceps operation should be done at once. This practice was safer than the waiting policy. Traction should be slow, gradually increasing in force until the soft parts in front of the head were stretched. Then the head should be held for about one minute before traction was slowly relaxed. After a rest of three or four minutes, traction should be resumed. By this mode of procedure delivery could be effected with an intact pelvic floor in a surprisingly large percentage of cases. Immediately after the delivery of the head, the mouth and eyes of the child should be wiped out, if possible, before the first effort at inspiration. The interval between the second and the third stage was the time when infection was most likely to occur. It was rare that an internal examination was required in normal cases after the birth of the child. Before attempting to deliver the placenta, the hands should be sterilized again, and after an interval of twenty or thirty minutes the placenta should be expressed. The length of this third stage depended upon the firmness of the uterine contractions. It was his custom, after the delivery of the placenta, to give a hot sterile douche, as this stimulated uterine contraction, removed clots, and enabled the obstetrician to inspect the parts and readily detect even slight tears of the birth canal. The use of gloves had not proved satisfactory. The speaker said that ether possessed many advantages over chloroform, and should be used, as a rule, when the pains were of moderate severity. He had not yet employed the new method of spinal anæsthesia sufficiently to be able to express an opinion regarding its value or possible dangers.

Technique on Closure of Abdominal Wall.

NOBLE describes the successive methods which he has been led to use in suturing up the abdominal wall in laparotomy operations. He has given up silk-worm gut for abdominal suturing, and uses catgut exclusively, closing the walls in the following manner: (1) The peritoneum is closed with fine cumol catgut. (2) The aponeurotic sheath of one rectus muscle (the right) is then separated from the muscle by blunt dissection, thus baring the under surface of the aponeurosis. The upper surface of the aponeurotic sheath of the left rectus muscle is then dissected clear of fat, with the object of suturing

the under surface of the right aponeurosis upon the upper surface of the opposite aponeurosis. The suturing is then begun by passing the needle, armed with medium chromicized catgut—sterilized by the cumol method—through the aponeurosis of the rectus muscle of the left side of the wound, and thereafter by continuous suturing, closing the rectus muscle until the opposite end of the wound is reached. The needle is then brought from below upward, through the aponeurosis on the left side of the wound. The aponeurotic layer is then closed by passing the needle from below upward through the aponeurosis on the right side; then passing it through the aponeurosis of the left side, as in the LEMBERT intestinal suture; and again from below upward through the aponeurosis of the right side, and so on till the end of the wound is reached, when a single knot completes the closure of the muscles and fascia. The subcutaneous fat is then closed with a continuous catgut suture in one or more layers using fine catgut. The skin is next closed by the intracuticular stitch with fine catgut. Scrupulous care is given to these methods to control all the bleeding vessels. The wound is washed repeatedly with salt solution to prevent blood clots and remove the germs. The method of cleansing the patient and the operator's hands is given in detail, and the different steps of operation illustrated. From his results he concludes that celiotomy wounds, which cannot be closed without drainage and suppuration, can be reduced to 2 per cent. or less, and that post-operative ventral hernia can be reduced to a fraction of 1 per cent.

Anteflexion.

AN analysis of his experience in operative treatment of anteflexion leads BURRAGE to lay down the following rules for guidance in these cases: (1) In anteflexion without ovarian or tubal disease, and free from shortened uterosacral ligaments or posterior adhesions, dilatation, curetting and DUDLEY'S operation or amputation of the cervix, with a preference for the former. (2) In anteflexion with retroposition and shortened uterosacral ligaments or posterior adhesions, and without ovarian or tubal disease, dilatation, curetting and division of the uterosacral ligaments or adhesions by colpotomy and DUDLEY'S operation or amputation of the cervix, with a preference for the former. Amputation of the cervix is a useful operation where the cervix is very long, and also where there is extensive erosion of the crown of the cervix. In married women, in both of the foregoing classes, dilatation and curetting without other operation are sufficient, because pregnancy will usually straighten the uterus and stretch the ligaments and adhesions. Should pregnancy not supervene within a number of months, and should the symptoms persist, another curetting and DUDLEY'S operation, with or without division of the ligaments, may be done. (3) In anteflexion, with or without retroposition, having ovarian or tubal disease, dilatation, curetting, DUDLEY'S operation, and suspensio uteri, the uterosacral ligaments being divided through the abdominal wound if they are shortened and whatever may be necessary done to the ovaries and tubes.

Treatment of Genital Prolapse in the Woman.

COVILLE divides prolapse into three sections: (1) Partial prolapse; (2) complicated prolapse (tumors, hypertrophies, or uterine deviations); (3) complete prolapse. Prophylaxis should consist in keeping the parturient woman in bed from ten to twelve days at the least. Any laceration should be immediately repaired. Curative treatment should consist in operating for prolapse, whatever the degree, unless there exists the contraindication of an inoperable malignant tumor. The time of pessaries has passed and ought now to give way to surgical treatment, rational and benign, and which promises to the patient not only relief from suffering, but the integrity of her functions—*La Presse Médicale*.

PHYSIOLOGY, PATHOLOGY, AND BACTERIOLOGY.

Anatomy of the Accessory Nasal Sinuses.

G. BRUHL describes a new method of demonstrating the exact position of the sinuses and their relation to surrounding structures. The heads are immersed in an acid solution of formalin, then treated with alcohol and ether, and finally with carbolized xylol. The cavities are filled with a molten mixture of lead, tin, bismuth, and cadmium, called WOOD'S metal, which soon hardens. They are finally submitted to the x-ray process, which brings out a dark spot wherever the metal has penetrated. The positions of the sinuses are definitely located in the radiograph.—*Berliner Klin. Woch.*

Physiology of the Labyrinth: A New Theory of Hearing.

J. W. BARNETT gives an abstract of this new theory as originally propounded by J. RICH EWALD. He calls it the "Sound-Picture" theory, and gives the following as its ground principle: membranes can vibrate in very different manners. They can form a vibration type of their own when they give out their own special tone. They vibrate then in a manner similar to plates which show CHLADNI'S figures. In the telephone and the phonograph, membranes vibrate as a whole when influenced by sound waves—that is, without nodal lines. They follow the sound waves, and for this purpose must not be too thin or too flexible, and especially if they are very extensible, not too weakly stretched. Finally, they can be stretched on a frame, and if impulses act on them, they can create moving waves. If these are reflected from the frame, so that the impulse is given out from opposite ends at the same time, then the stationary waves are created which produce a characteristic picture for the given impulse. In this case, the membrane must be as thin as possible, as flexible as possible, and at least in one direction as little stretched as possible. In the ear, the impulses falling on the ground membrane create a sound-picture, whose special form enables the ground membrane to create a link in the chain of the transmission apparatus, which intervenes between sound and sound sensations. This is the ground principle of the sound-picture theory, no more and no less.—*Intercolonial Medical Journal of Australasia.*

Etiological Relations between Traumatism and the Formation of Neoplasms.

ON account of the varying opinions as to the etiological value of traumatism in the production of neoplasms, LENGNIK has studied 579 cases of malignant tumors treated in the surgical clinic of Königsberg. Out of thirty-one cases in which the patients attributed the origin of the tumor to a trauma, seven times this statement seemed wholly improbable; twelve times the influence of the trauma was evident; in the remaining twelve cases there was doubt. The following observation seems very significant: A young man, aged thirty, fell and received a severe contusion of the genital organs. There was formed a swelling of the left half of the scrotum. This was tapped three weeks after the accident, and half a litre of dark blood was drawn from it. This was followed by a purulent infection, making it necessary for the man to enter the hospital of Eiselsberg. An incision was made, and this afforded proof that the testicle was necrotic and that the spermatic cord was perceptibly thickened. The testicle was removed and the wound plugged. The microscopical examination of the cord showed that it was a case of myxosarcoma. This diagnosis was confirmed by the clinical course of the affection, since, on the surface

of the wound, there appeared numerous nodules which were not long in presenting the characteristic features of a relapse. Another operation showed that the neoplasm had already invaded the abdominal cavity, following the spermatic cord. Five weeks later the patient died, and the autopsy confirmed the diagnosis of sarcoma of the cellular tissue with metastasis in the lungs and liver.—*Translated from Giornale Internazionale delle Scienze Mediche.*

Pathogenesis of Gout.

THE author's summary concerning the pathogenesis of gout rejects the old view of GABROD that the essential element of gout is the deposit of uric acid in the joints, and believes that this deposit is only a symptom, as is also the increase of uric acid in the blood. The deposit occurs in the joints secondarily to a necrosis in the joint tissues. This necrosis is brought about by the irritating action of certain alloxur compounds, particularly adenin, circulating in the blood. It has been shown that before the outbreak of an attack of gout there is a retention of nitrogen in the system. This retention is not accompanied by an increase in weight, and is to be credited to the presence of nitrogenous extractives of the alloxur or uric acid group. The adenin is the most harmful, producing necrosis of the tissue-cells. Why it does so in certain particular organs or parts, like the joints, is not definitely known, but it probably depends upon anatomic conditions. The necrosis induces an extensive disintegration of tissue-cells, and the decomposing nucleins of the latter lead to an accumulation of alloxur bases and uric acid in the blood. The uric acid thus produced, or that existing pre-formed in the blood, is deposited in the affected parts as tophi. The recent theory of LUFF, according to which the primary fault is in the kidneys, is rejected by HAGER.

Pancreas in Relation to Sugar Reduction and Diabetes.

UMBER has carried out a series of experiments to test the observations of BLUMENTHAL that the expressed tissue juices of the liver, spleen, and pancreas have a reducing action on grape sugar, most active in the case of the pancreas, least in that of the spleen. UMBER finds that if the pancreas is excised with aseptic precautions and all foreign matter excluded, the expressed juice has no reducing capabilities. He also excised portions of pancreas from a living dog and added them to a sugar solution, but four days' digestion produced no result. Experiments were also made on the glycolytic action of blood; this was taken from different vessels, including the pancreatic vein, directly into sterile slightly alkaline sugar solution; a distinct though small reduction was observed, but there was no difference between the blood from the pancreatic vein and other specimens. These experiments would seem to disprove the idea that the derangement of glycolysis in diabetes is due to the absence of certain pancreatic sugar-reducing ferments.—*Brit. Med. Jour.*

Cancer Parasite.

CURTIS, of Lille (*Brosse méd., Paris*), has obtained entirely negative results in a series of experiments which he has carried out for over four years. He considers that tissues taken from superficial epithelium are not good, on account of their liability to contamination. Tissues from the breast and testicles are better. In eighteen such cases, and a careful series of experiments, he failed to obtain any growth on any media, or to produce contagion in other animals. He therefore concludes that positive results have been obtained only through imperfect technique.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Two Cases of Extreme Brevity of Vaccinal Immunity.

CHARLES VIANNAY cites these cases, which occurred in his own family, one five months after a successful vaccination, the other seven months. The disease was contracted by both individuals as they were nursing the writer, who was suffering from an insignificant attack of varioloid. The writer had been previously vaccinated six times without success, and then contracted the disease by making an autopsy on a virulent case. One of the first symptoms of invasion in the cases noted was aching of the legs which preceded the backache. During convalescence, the least fatigue caused a sensation of extreme lassitude in the legs. The history of these three cases would seem to indicate a family susceptibility to this disease.—*Lyons Med.*

Examination in Practical Hygiene for School Teachers.

No examination has hitherto been established suitable for school teachers desirous of showing knowledge in practical hygiene, and we learn with satisfaction that the Council of the Sanitary Institute, which has for the past twenty years been holding qualifying examinations for official sanitary appointments, has decided to arrange a thorough theoretical and practical examination which will be open to teachers and to those preparing as teachers. The syllabus includes: (1) Practical hygiene, individual and social, including the necessary physiology (students will be tested in their knowledge of foods, clothing, physical exercise, first aid in school accidents, infectious and other complaints); (2) hygiene of schools and private dwellings (structural), water-supply, drainage, and disposal of house refuse, warming, lighting, and ventilation; (3) hygiene in education. The student will be required to show a special knowledge of the health laws relating to bodily condition of childhood; the laws of health relating to mental condition of childhood; the psychological working of child's mind in acquiring knowledge; the using of various senses to vary the work of the brain; the ethics of character building; the mental presentation of moral forces as an aid to character formation; details of food and clothing from youngest infancy to six months, from six months to two years; principle of feeding and clothing to eight years; the purpose of a child's skin and internal organs in throwing off effete matter from the body in perspiration, refuse, etc.

Medico-legal Experiences.

In this address MILLS gives some interesting experiences in medico-legal cases, showing the tricks of lawyers and the peculiar position in which the medical witness often stands. He cautions witnesses against giving views regarding the books used by the examining counsel, as it is common practice to try to catch the doctor in endorsing what does not there exist. He shows the defects of expert testimony, and the probable reasons why it is ineffectual in many cases; prejudice is one of these, as in the celebrated GUILTEAU case. He thinks that the official expert system will never succeed in this country. The real way would be for the experts on both sides to examine the case together, and consult about the condition frankly and freely without any effort to come to an agreement for the mere sake of doing so. While the present system is probably the best, it is not always properly made use of. Very much depends on the competency of the experts, which it is needless to

say is not always provided for. In conclusion, he speaks about the physician's conduct as a witness, making the following points: (1) That the witness should not go outside of his own province. (2) That his testimony should be relevant and his manner respectful. (3) That he should always tell his story in plain language. (4) That he should never pose as an expert outside of his special line of work. When asked about the responsibility of persons on trial, he has on one or two occasions himself found it advantageous to disclaim being an expert on responsibility. While as a rule, repartee is not advisable, there are cases where it may be advantageous, but they are not common. The witness should learn not to say too much. It is exceptional, but it is also possible for the witness, through nervousness or modesty, to be too brief.—*New York Med. Jour.*

Husband's Liability for Care of Insane Wife.

THE Supreme Court of California has rendered decisions in two cases brought by the St. Vincent's Institution for the Insane *vs.* John T. Davis. One was for boarding and clothing his insane wife prior to June 1894, and the other was for keeping and caring for her, providing for her suitable boarding, lodging, clothing, washing, medicine, and medical and other attendance after that date. In both cases the court cites section 174 of the California Civil Code, which provided that, when a husband fails to make adequate provision for the support of his wife, then—except in certain cases—any person may supply her with necessities, and recover the value thereof from the husband. Under this rule, applied to the different circumstances of the two cases, in the first-mentioned case the Supreme Court affirms a judgment in favor of the St. Vincent's Institution for the Insane, and in the other case in favor of the husband. In the first case there was a very strong presumption that the husband had left his wife in a small town in Illinois, intending that her identity should be lost, that she might no longer be a charge upon him. Under such circumstances the court holds the husband would be liable for necessities, even though the parties supplying them did not know of his existence, or that the woman was married. And with regard to the contention that the evidence was insufficient to sustain a finding that the service was rendered on the credit of the husband, it being argued that it did not appear that he was even aware that she was being kept and provided for by the institution at all, the court answers that, even if he had no such knowledge, it would not follow that he was not liable, or that the service was not rendered at his request. But in the second case there was a finding that the husband, desiring in good faith to care for his wife elsewhere, had, in June 1894, demanded of the institution that she be delivered to him, and that the institution, without legal cause or excuse, had refused to comply with such demand, and against the will of the husband had thereafter retained the wife in its custody. Such being this second case, the court holds that no recovery for keeping and caring for her could be had therein, the section of the Civil Code quoted requiring that whoever supplies necessities to a wife must, in order to recover therefor, show neglect on the part of the husband to make adequate provision for her support, which was not shown in this case, it not being enough for the purpose that some suspicion was cast upon the motives of the husband, there also being some evidence tending to show good faith on his part.—*Phil. Med. Jour.*

THERAPEUTICS & PHARMACOLOGY.

Venesection and Saline Transfusion.

In the *Archives Provinciales de Médecine*, RAYNAUD has just concluded a serial article. The following is the author's own résumé: (1) Venesection by its depletive and depurative action is certainly the best method of mechanical disintoxication in all cases which represent a severe blood intoxication. It is not to be used as a routine procedure, but only in emergencies, and its beneficial effect is only temporary. (2) Saline injections should be used only hypodermically. Thus employed, they present none of the drawbacks of intravenous injections, although their action is somewhat less rapid. (3) Massive doses of saline solution may be employed in the treatment of medical hæmorrhages, in algid collapse, in the ataxo-adyndamia of typhoid affections, and in dysentery; but this remedy must always be used with discretion and with due regard to the state of the heart and kidneys. There are cases recorded of death due to the intemperate exhibition of saline transfusion. (4) Small fractional doses, as well as enemata of cold saline solution, may be used without fear in infections and intoxications, especially when there is vascular hypotension or difficulty in the action of the emunctories. It should be exhibited systematically from the onset of the disease in moderate quantities (150 to 500 c.c. daily). The general course and duration of the disease are often very favourably modified. (5) In all severe toxæmias or infections, when the patient's circumstances are desperate, venesection followed by massive injections without renouncing other methods of treatment is often capable of rendering the greatest services and even of saving life. One should not wait until the last moment before exhibiting the solution. (6) When the patient is too far gone for phlebotomy, it is still possible to withdraw blood and inject saline solution at the same time and in equal quantities, this procedure being a safe one.

Success of Mercury in Gonorrhœa.

A. PALDROCK says:—A patient had been long treated in vain for chronic articular rheumatism, which had first commenced about a year after a tedious, but finally cured, gonorrhœa. Inspired by BOTTCHEK's success with a case of general gonorrhœal infection cured with gray ointment, PALDROCK commenced a course of inunctions, and after 144 gm. had been rubbed into the patient in the course of five weeks, he was dismissed completely cured, and has had no recurrence during the year since. In another case of chronic gonorrhœa the cocci were found in the effusion of an intercurrent pleurisy. The writer concludes by suggesting that multiple articular affections with chronic, acute or past gonorrhœa should be treated with gray ointment even in the absence of syphilitic antecedents. Gonorrhœal articular affection is characterised by the rapid involvement of the ligaments and the small amount of exudate. Contraction, atrophy and ankylosis appear early. Such cases are by no means rare, but they usually masquerade as "chronic articular rheumatism."—*St. Petersburger Medicinische Wochenschrift*.

Diet in Albuminuria.

IN a paper on this subject read in the Section of Therapeutics at the recent International Congress of Medicine, Dr. A. ROBIN (Paris) said: It is recognised that the same system of diet is not suitable for all sufferers from BRIGHT'S disease. In particular, the exclusive use of milk causes in some of them an increase, at least for a time, of albumen in the urine. Further researches prosecuted for many years have convinced him that an exclusive milk diet diminishes albuminuria always less than a vegetable diet, sometimes even less than the use of meat alone. In all cases a mixed diet of milk and vegetables, or of milk and meat, has a better effect than the exclusive use of milk. The following is the system that he adopts for the purpose of ascertaining the regimen most suitable for each patient. He begins by giving only milk. This has the effect of first increasing the amount of albumen in the urine; then it diminishes and remains stationary. At this stage vegetables are added to the diet. New oscillations are then produced; when these have ceased, meat is cautiously allowed, whilst milk and vegetables are continued. In this way it is easy to ascertain which of the three systems of diet—milk, milk and vegetables, or milk, vegetables and meat—brings about the most marked diminution in the amount of albumen eliminated. It is important, also, to ascertain the value of each alimentary substance in regard to the production of albuminuria. Some researches which Dr. ROBIN has made on this subject have led him to the following conclusions: Bread has no effect on the albumen; wine causes an increase; amongst meats, beef and veal are more to be recommended than mutton or fowl; fish should be forbidden.—*Brit. Med. Jour.*

Powder for Gastric Acidity.

As the result of much experience, Professor PEL, of Amsterdam, recommends this formula:—

R Sodium bicarbonate	2½ drachms.
Calcined magnesia	2 "
Sodium bromide	2½ "
Bismuth carbonate	1½ "
Sugar of milk	2½ "
Oil of fennel	4 drops.

M. From half a teaspoonful to a teaspoonful to be taken an hour or two after eating, and a special dose in case of pain.—*New York Medical Journal*.

Lotion for Diabetic Pruritus Vulvæ.

LUTAUD (*Journal de Médecine de Paris*) gives the following formula:—

R Boric acid	750 grains.
Sodium bichlorate	75 "
Distilled water	1 quart.

For Craving for Morphine or Spirits.

R Ammon. bromidi	gr. v.
Ext. bellad	fld.
Ext. nuc. vom	fld.
Ext. cannabis ind	fld. aa m. ij.
Aque	ad 3 ij.

A dose four times a day.

Correspondence.

GRIEVANCES OF CIVIL ASSISTANT SURGEONS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—I have read with much interest the letters of TOMTIT, M.B., published in your previous issues. This gentleman has very ably put forth the grievances of the Civil Assistant Surgeons in a serial form. He has brought forward all the chief points; but I fear it will be a voice in the wilderness—unheard and unheeded. The Civil Assistant Surgeons have all along been quite blind to their interests, and their position has gone day by day from bad to worse. The ordinary natural law of evolution has not found application in their case, and if it has, it has progressed in the retrogressive order. Their position and prospects have gone lower and lower day by day, because those who do not go forward are bound to fall backwards, there being no standing still in this universe.

The sister services have progressed forwards slowly, if not by leaps, and left the unfortunate Civil Assistant Surgeons in the shade. When the service was inaugurated, a Civil Assistant Surgeon was a gazetted officer; but what is he now? He is a gazetted officer still, so far as the word goes. His appointment is gazetted. His leave and promotions are gazetted; but has he any of the privileges which, in the eye of the public, distinguish a high official of gazetted provincial service from members of the subordinate service? All these points have been discussed by TOMTIT in his letter.

Looking over the rules under the Indian Arms Act, giving the names of officers who are exempted from the prohibitions of keeping arms without a license, one cannot but wonder. Paras. 3 and 4 of Rule I partly run as follows:—

(3) All military and naval officers, all soldiers (including reservists), sailors, volunteers, and such officers of the Police (including members of Thugi and Dakaiti Department), Forest, Postal, Telegraph, Jail, Salt, Opium and Excise Departments, as the Government by special or general order may direct.

(4) All Magistrates, Justices of the Peace, Deputy Collectors, Honorary Magistrates and Judicial Officers of or above the rank of Munsiffs, and officers of P. W. Department of and above the rank of Assistant Engineers.

Are not all the departments of State enumerated, with the exception of the Medical Department? The highest head of the department as such has not been exempted. He may be exempt, but not as head of the Medical Department. A Naib Tahsilidar is exempt, because he is a Magistrate; but a Civil Surgeon is not, unless he can claim exemption as European, East Indian, Volunteer or Jail Officer. This is not only degrading to the Civil Assistant Surgeons, but to the whole Medical Department.

Does not the Government think that the reasons which lead to the exemption of the officers of so many other departments hold equally good in the case of medical men? Are they less trustworthy than the rest? Are not their education and general attainments sufficiently high to entitle them to claim this exemption, or have they no necessity to keep and carry arms? A Magistrate runs the risk of making enemies among people by punishing criminals, and so requires arms to protect himself; but a medical man runs just the same risk, by appearing as the legal witness in such cases. Why, then, does he not require to protect his life?

Magistrates always go attended by their peons and orderlies—an advantage which the medical men have not. Almost all other officers can rent a house in whatever locality they think best, while medical officers have to occupy quarters supplied to them in the dispensary, and

the dispensaries are, as a rule, situated outside the towns, and cannot boast of the protection afforded by a watchman or constable. In case of an accident, a medical man, located as he is, would be utterly unable to defend himself, and protect himself, family and property. Almost all other officers are perfect masters of their time (excepting the few office hours). Their duties do not require them to leave their homes or offices at every call; but that is not the case with medical men.

The Mussoori case must be fresh in the memory of all, when the moral and legal duties of a medical man were discussed.

The concensus of opinion then was that it was the moral duty of a medical man to attend an urgent case when called out, even to a distance, and even in the middle of the night. If the pretended case be merely an excuse to enslave him (for in more than half the cases he does not personally know the party calling him out), is it not necessary that he be amply provided for an emergency of this nature? Even ignoring such an extreme case, does he not incur any risk by going out at night to see a patient, either alone or attended very poorly?

The Government may be justified in ignoring many desirable reforms which require money, on the score of want of funds; but what reason can be given for things like this?

Let us hope that they were not given this exemption, because probably they never asked for it; nor was the matter ever brought to the notice of the Government, and that now the higher medical authorities will interest themselves, and the Government will lose no time in removing this disability from this hardworked class of officers of the Government, and earn their gratitude for an act of justice which will cost the Government not a single pice.

Yours, &c.,
A MEDICO.

THE SHEFFIELD-TALLERMAN TREATMENT OF SCIATICA, ETC., BY LOCAL DRY HEAT.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—Since I last wrote to you, I have been at death's door, and I am still a cripple. But I have had so much benefit from the Sheffield-Tallerman treatment by local dry heat, that I feel I must send you an account of it, in case you and your friends should like to introduce it in India, where it would be useful in some troublesome cases.

I went home to have an operation for the radical cure of hernia performed. In the enforced stillness of the position after operation, gout developed, for which I was sent to Buxton in Derbyshire, the water of which is of a very composite nature. The water has no bad taste or smell, but is strongly diuretic, and after the "water cure" I was sent to the seaside for the "air cure," and I remained at Folkestone. Then I went to London.

Just as my wife was starting for home in October, when you know the cold is very moderate in London, I stumbled in the street, and felt so much pain in my right hip, that I thought I must have injured it somehow. I drove home and went to bed, where Mr. B. examined me, and said there was no injury, but a very sudden attack of sciatica, which I had never had before, and which prevented me from moving without great pain. As I wanted to meet my wife at Marseilles and go to Nice with her for the winter, this was a serious matter, so I went to 50, Welbeck

Street, Cavendish Square, to try the local application of dry heat, which you will find fully described in the *Strand* magazine for September 1900, illustrated with photographs.

The heat is very soothing, the pain seeming to melt away by degrees, so that after ten "bakings," one every other day, I was able to join my wife, and here we are for the winter, the climate being now very like that of Upper India in the cold weather. Each patient has a comfortable room to himself with a fire in it, and hot water after the bath to wash off the sweat. A man helps you to undress, and dress again after rubbing you dry. You take off your clothes, put on a sleeping suit, and lie down on a bed, wrapped up in sheet and blankets, a nurse remaining with you all the while to observe and record temperature, pulse, etc., wipe your face and give you water to drink.

The heat for the limbs is electric dark heat, the heat for the thorax or pelvis is by gas, and I assure you that 300°F. thus applied feels less oppressive than 150°F. in a Turkish bath. The only places where the heat feels at all uncomfortable are the elbows and the shins, where the covering of the bones is thin; but you are easily protected there by applying lint folded several times thick.

In my case the pulse was raised from 76 to 86, and the temperature from 98.4°F. to 100.4°F., and once to 101°F. The baking lasts about 40 minutes, but as soon as the patient begins to feel the pulse throb, or the heart begin to palpitate, the nurse stops the heat at once. The man then comes and helps you to dress, etc., and you stay in a sitting-room half an hour afterwards, reading the papers, till you are cool enough to go home. I have had no recurrence yet.

I need not tell you how troublesome sciatica often is, and how inconvenient it is for people to go home on sick leave for it at a moment's notice, to say nothing of the expense; so it occurred to me that perhaps you might think it worth while to treat people by this method. You will see by the published cases that the local heat is useful not only for sciatica, but also for gout, rheumatism, rheumatic gout, writer's cramp, and chronic eczema, which may have resisted all ordinary treatment, and you know all of these cases occur in India as well as in Europe.

Wishing you the compliments of the Xmas and New Year, in case I may never live to see another such season.

Yours, &c.,

LT. COL., I. M. S. (retired).

NICE, FRANCE; 21st November 1900.

AMERICAN MEDICAL FRAUDS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—Your exposure of the American medical frauds that have recently been perpetrated in this country, ought to go far towards determining the Government to pass a Medical Act. The fact that Government has gone out of its way, as it were, to warn people against the imposture is sufficient indication, I think, in concluding that our rulers are not entirely callous to their responsibilities in this connection. But there is another serious aspect to this matter of medical frauds in India, viz., that besides the purchasers of American bogus diplomas, we already have bolder impostors who, without going to the expense of purchasing diplomas, are in large centres of population setting themselves up as "Medical Practitioners," with alphabetical affixes to their names, intended to convey to the ignorant the possession of academic titles—an instance of this I can at this moment point to in the place I am residing. Here the individual has not had even an elementary medical education. When I have condemned the imposture, my statements have been met often with incredulity, because

it is contended that the State would not permit such glaring imposture as that of a man not only advertising himself in a lay newspaper, but flaunting a signboard in English and a couple of vernaculars. To explain that in the absence of a Medical Act such imposture was untouchable was rarely to carry conviction.

Fortunately for us, gentry of this kidney work out their own condemnation with all but the illiterate, sooner or later, inasmuch as it soon becomes evident that they are unable to uphold their pretensions. A surgical case or two, or one of difficult accouchement, generally proves too much of a test. But, then the army of illiterates, especially in things medical, is a mighty host, and is the salvation of the quack.

The step of passing a Medical Act for India no doubt is beset with difficulties, but with the advance of education amongst the native population, these difficulties must have considerably diminished within the last half century. The aids afforded by Western medicine are more and more freely resorted to every day, even by the rural population. In towns and large centres of civilisation, the European doctor is certainly more in evidence amongst all classes than the native *hakim*.

It is in such places that a Medical Act is sorely needed, and would not be felt as a hardship. The majority of lay people believe that Government does enforce some restraining measure on individuals who undertake the cure of disease without a license; it is only a small minority know the contrary, and it is from the ranks of these latter that the medical impostor is recruited. In short, the time has arrived when something more than a gazette notification warning the public is needed: people must be legally protected from a species of fraudulent dealing that they are not in a position to detect themselves.

Yours, &c.,

L. R. C. P. & S.

A HOAX OF A BINAURAL STETHESCOPE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—On receipt of an advertisement sent by B. M. NARAIN and Co., Chemists, Egerton Street, Delhi, I applied for a copy of the book and a binaural stethoscope, as I thought that the latter would be of some use. But to my surprise, when I unpacked the parcel, I found two broken pieces of wood and two pieces of India-rubber tube, each two feet long. I think it would do well for Mr. RAM NARAIN, L. M. & S. (Lahore), the author of the book referred to above, to request Messrs. B. M. NARAIN & Co., Chemists, not to advertise his book along with the one for a "binaural stethoscope." I enclose the post-card and advertisement, and write this for publication in your valuable journal, so that the readers of your journal may know the nature of the binaural stethoscope referred to in the advertisement.

Yours, &c.,

A SUFFERER.

(We have seen the post-card advertisement referred to. It purports to give a binaural stethoscope worth Re. 1-8 to all purchasers of Dr. Ram Narain's book. We publish this letter as an apparently legitimate complaint, and as a warning to others.—Ed., I. M. R.)

TRADE NOTICE.

THE PASTEUR (CHAMBERLAND) FILTER.—J. Defries and Sons, Ltd., 147, Houndsditch, London, has for a number of years been the acknowledged standard filter in scientific laboratories. Extensive experiments have proved its efficiency, but it is no longer necessary to infer this from laboratory experiment only. The statistics of the French army, in 245,000 quarters of which it is used, give more direct proof. They show that, under all kinds of circumstances, typhoid fever, cholera, and other water-borne disease, ceases on its use. Filters in which powdered or granulated carbon or sand are used, not only let the germs contained in the water pass, but also constitute an excellent culture medium for these, which are more numerous in the filtered than in the unfiltered water. The basis on which the Pasteur Filter is constructed is neither carbon nor sand. It was found that by taking certain mixtures of earths and preparing them under a particular process tubes could be made from the mixture which were all exactly like each other in appearance, and that some of these tubes had the property of removing infective bacteria from water. The actual ingredients and process of manufacture are a secret. Each tube is tested for bacterial soundness under the direction of Dr. CHAMBERLAND, of the Pasteur Institute, before it is employed in the construction of any filter.

Government Medical Gazettes.

BENGAL.

Asst. Surgn. Syed Mahomed Afzal is apptd. to act a House Physician, 2nd Physician's Ward, Med. Coll. Hosp., Calcutta, during the absence, on leave, of Asst. Surgn. Hari Nath Ghosh.

Asst. Surgn. Nitro Gopal Mitter, late of the Lalbagh Disp., is allowed leave for one day, in extension of the leave granted him.

The following Asst. Surgn. of the Bengal Estab. have passed the Septennial Exam., held at the Med. Coll., Calcutta, on the 5th Nov. 1900, and promoted to the grades noted against their names:—

Ganesh Chandra Mitter, Hatwa Raj Disp., 1st grade, 1st Nov.; Ananda Proshad Ghosh, Offg., Goalundo sub-divn., 1st grade, 1st Nov.; Lohit Mohun Laha, Patna City Disp., 1st grade, 1st Nov.; Bhagabuttu Kumar Chowdhury, Offg., Sambhu Nath Pandit Hosp., 2nd grade, 1st Nov.; Nrinrendro Nath Basu, Offg. Teacher of Medicine, Midwifery and Physiology, Dacca Med. School, 2nd grade 22nd May; Baroda Kanto Roy, Muzaffarpur, Disp., 2nd grade, 1st Nov. 1900.

BOMBAY.

* The undermentioned are granted leave:—

Asst. Surgn. H. A. Lafond, I.S.M.D., privilege leave for one month, from the 25th Oct. 1900.

Civil Med. Pupil Ganpat Rajanna Avar, Civil Hosp., Ahmednagar, sick leave for three months, from 5th Sept 1900.

The following promotion is made in accordance with Govt. of India Resolution dated 16th Jan. 1878:—

Second Class Hosp. Asst Girdharilal Dhanaji, to be Hosp. Asst. First Class, from 1st Oct. 1900.

Hosp. Asst. Gangadher Ramkrishna returned from famine duty and received ch. of the Bhambgaon Disp. from the 20th Sept. 1900.

Asst. Surgn. George C. McMullen, I.S.M.D., relieved from the ch. of Civil Surgeoncy and Ry. Med. duties at Sukkur on the 28th Aug. 1900, rejoined the Ry. Med. duties at Kotri, on the 29th Aug. 1900.

Asst. Surgn. Bhau Govind, B.M.S., relieved from the ch. of Ry. Med. duties at Kotri on the 29th Aug. 1900, rejoined the Jamnabai Disp., at Tata on the 30th Aug. 1900.

Hosp. Asst. Chothiram Pessusing was relieved from cholera duty, Thar and Parker Dist., on the 18th Aug. 1900, and placed on med. treatment at the Civil Hosp., Hyderabad.

Hosp. Asst. Chothiram Pessusing discharged from the Civil Hosp., Hyderabad, on the 25th Aug. 1900, and placed on gen. duty, Karachi, 27th Aug. 1900.

Hosp. Asst. Maganlal Kessoni is dismissed from the service from the 29th May 1900.

Asst. Surgn. James Earnest Barton Macqueen, I.S.M.D., Asst. to the Surgn. to His Excellency the Govr., held independent ch. of His Excellency the Govr's Body Guard, Household Estab. and Army Transport men at Ganeshkhind from 5th to 6th Sept. 1900.

Hosp. Asst. Shaik Lalbux Shaik Khudabux ceased to do plague duty at the Crater Plague Hosp., Aden, on the 10th June 1900, and received ch. of his duties at the Civil Hosp., Aden, on the 11th June 1900.

The undermentioned are admitted into the Dept. as Hosp. Assts. as a tempy. measure on the salaries stated against their names:—

Nathalal Sakarial Bhagat, 1st Aug. 1900, Rs. 35 per month; Manishanker Gaorishanker, 20th Feb. 1900, Rs. 20 per month.

The services of the undermentioned tempy. Hosp. Assts. have been dispensed with from the dates stated against their names:—

Ramchander Shridher Sahasrabudhe, 1st Sept. 1900; Narayan Vishnu, 29th June 1900; Ramchander Venkatesh, 18th Sept. 1900; Chandulal Beharilal, 1st Sept. 1900; Shaik Wazeer 14th Oct. 1900.

The undermentioned civil med. pupils have repaired to the Byramji Jijibhoy Med. Schools at Poona and Ahmedabad, and have reported themselves to the respective Supdts. of the Med. Schools.

Byramji Jijibhoy Medical School, Poona.

Dasharath Krishna Powar, Civil Hosp., Satara; Dwarkanath Sitaram Javeri, Civil Hosp., Satara; Shivabasa Sidhapa Tipabetti, Civil Hosp., Belgaum; Mayad Budhan valad Sayed Hussein, Civil Hosp., Karwar; Balwant Ramji Marathe, Civil Hosp., Dhulia; Mohomed Ibrahim Khan, Civil Hosp., Dhulia; Anandrao Shamrao Wagh, Civil Hosp., Dharwar; Wishwanath Govind Kulkarni, Rustomji Wadia Disp., Thana; Lalising Dhansin, Civil Hosp., Kaira; Ganpatrao Baburao Dalvi, Civil Hosp., Ratnagiri.

Byramji Jijibhoy Medical School, Ahmedabad

Ramchander Rajaram, Civil Hosp., Panch Mahals; Jamaludin Amirliya Kazi, Civil Hosp., Kaira.

BURMA.

Hosp. Asst. B. Sanyasy relinquished ch. at the Police Hosp., Shwabo, on the 5th Nov. 1900, and assumed ch. at the Police Hosp., Myitkyina, on the 10th Nov. 1900.

Hosp. Asst. B. Sanyasy relinquished ch. at the Police Hosp., Myitkyina, on the 11th Nov. 1900, and assumed at the Outpost Hosp., Loignu, Myitkyina dist., on the 18th Nov. 1900.

Hosp. Asst. U. Raman Nair relinquished ch. at the Outpost Hosp., Loignu, Myitkyina dist., on the 18th Nov. 1900, and assumed ch. at the Police Hosp., Myitkyina, on the 23rd Nov. 1900.

Hosp. Asst. K. P. Kannan Nambiar, on proceeding on six months' leave on medical certificate, relinquished ch. at the Police Hosp., Katha, on the 23rd Nov. 1900.

Hosp. Asst. Syed Asghar Hussain assumed ch. of additional duties at the Police Hosp., Katha, on the 23rd Nov. 1900.

Hosp. Asst. Ram Prasad Sinha relinquished ch. at the Police Hosp., Mogaung, on the 16th Nov. 1900, and assumed ch. of the Outpost Hosp., Kamaing, Mogaung subdn., on the 18th Nov. 1900.

Hosp. Asst. Ram Prasad Sinha relinquished ch. at the Outpost Hosp., Kamaing, Mogaung subdn., on the 23rd Nov. 1900, and assumed ch. at the Police Hosp., Mogaung, on the 25th Nov. 1900.

Hosp. Asst. J. P. S. Mullens, on proceeding to Mogaung to attend court, relinquished ch. at the Outpost Hosp., Kamaing, Mogaung subdn., on the 18th Nov. 1900, and on return assumed ch. at the Outpost Hosp., Kamaing, Mogaung subdn., on the 23rd Nov. 1900.

Hosp. Asst. J. P. S. Mullens made over, and Hosp. Asst. Ram Prasad Sinha assumed, ch. of the additional duties at the Civil Hosp., Kamaing, Mogaung subdn., on the 18th Nov. 1900.

The following Hosp. Assts. availed themselves of the leave granted with effect from the dates noted against their names:—

Hosp. Asst. Bishen Lal, from the 7th Nov.; Bhola Ram, from the 21st Nov.; Gobind Ram, from the 22nd Nov. 1900.

The following Hosp. Assts. on transfer to Burma, having reported their arrival from India, are posted to the stations noted against their names:—

Abdul Hussain, Myitkyila; Naziruddin Ahmed, Bhamo; Abdul Karim, Bhamo.

Major J. H. Sellick, I.M.S., made over, and Capt. G. Barry, I.M.S., assumed, executive and med. ch. of the Mandalay Central Jail on the 7th Nov. 1900.

Capt. E. R. Röst, I.M.S., made over, and Capt. E. G. Forrest, R.A.M.C., assumed, executive and med. ch. of the Melkilla Dist. Jail on the 2nd Nov. 1900.

PUNJAB.

Asst. Surgn. Khazan Chand, Sialkot Civil Hosp., has obtained one month's privilege leave, and was relieved of his duties on the 2nd Nov. 1900 by Asst. Surgn. Abdul Aziz, transferred from gen. duty, Amritsar.

Hosp. Asst. Karm Elahi, Gurgaon Sadr. Dispy., to the additional ch. of the Police Hosp., Gurgaon.

Hosp. Asst. Gokal Chand, at present in ch. of the Jail and Police Hosps., Dharamsala, is permitted to change his name to Bhadar Sen.

Hosp. Asst. Doola Ram, at present in ch. of the Chindwan Dispy., Dera Ismail Khan Dist., is permitted to change his name to Sukh Dev.

Hosp. Asst. Abbas Ali, doing gen. duty at Umballa, was apptd. as a temp. arrangement to the Karnal City Dispy., from the 21st Oct. 1900, relieving Hosp. Asst. Abdul Wahab Boff, who was placed on gen. duty at that stn.

Asst. Surgn. Ghulam Muhammad, doing gen. duty at Hissar, was apptd. to the ch. of the Karnal Sadr Dispy. on the 22nd Oct. 1900, relieving Asst. Surgn. Umrao Raja Lal, who was apptd. to do gen. duty at that stn.

On being relieved of the duties of Travelling Hosp. Asst., N.-W. Ry., Lahore Section, 1st Class Hosp. Asst. Kahi Khan was apptd. to do gen. duty at the Wazirabad Dispy., Gujranwala Dist., on the 4th Nov. 1900.

Hosp. Asst. Shabbir Hussain, doing cholera duty at Kohat, was attached to the South Waziristan Militia Regiment from the 6th Nov. 1900.

Hosp. Asst. Waryam Singh, Sangla Dispy., Gujranwala Dist., has obtained three months' privilege leave, and was relieved of his duties on the 1st Nov. 1900 by Hosp. Asst. Arjan Das, transferred from the Sialkot Civil Hosp.

Hosp. Asst. Khwaja Ahmad, Palampur Dispy., Kangra Dist., has obtained two months' privilege leave, and was relieved of his duties on the 4th Nov. 1900 by Hosp. Asst. Kahan Singh, transferred from cholera duty in the Gurdaspur Dist.

On being relieved of the ch. of the Pindigheb Dispy., Rawalpindi Dist. Asst. Surgn. Shankar Das was apptd. to the Murree Dispy., in the same dist., from the 10th Nov. 1900, relieving Hosp. Asst. Lal Singh, who was apptd. to do gen. duty at Murree.

Hosp. Asst. Imam-ud-din, Attock Dispy., Hazara Dist., and in med. ch. of the lock-up, has obtained 15 days' privilege leave. He was relieved of his duties on the 10th Nov. 1900 by Hosp. Asst. Jaggan Nath, transferred from the Rawalpindi Civil Hosp.

Hosp. Asst. Siraj-ud-din, doing gen. duty at the Civil Hosp., Jullundur, was transferred to the Dera Ghazi Khan Dist. He reported himself to the Civil Surgn. on the 24th Oct. 1900, and was apptd. to do cholera duty in the dist.

Hosp. Asst. Hari Chand, doing gen. duty at the Civil Hosp., Sialkot, was apptd. to the ch. of the Wadala Dispy., in the same dist., from the 5th Sept. 1900, relieving Hosp. Asst. Jowahir Singh.

On being relieved of the ch. of the Wadala Dispy., Sialkot dist., Hosp. Asst. Jowahir Singh was transferred to the Gobains Dispy., Rohtak Dist., on the 14th Sept. 1900, relieving Hosp. Asst. Mumraiz Khan.

On being relieved of the ch. of the Kalka Dispy., Umballa Dist., Hosp. Asst. Fatah Muhammad reverted to the ch. of the Ramnagar Dispy., Gujranwala Dist., on the 1st Sept. 1900.

Hosp. Asst. Mula Mal resumed ch. of the Farukhnagar Dispy., Gurgaon Dist., on the 1st Nov. 1900.

Asst. Surgn. E. S. Baillie was apptd. Med. Offr., Southern Punjab Ry., Bhatinda Sec., from the 12th Oct. 1900, relieving Milly. Asst. Surgn. H. W. V. Cox.

Hosp. Asst. Sat Ram, N.-W. Ry. Hosp., Saharanpur, has obtained two months' privilege leave, and was relieved of his duties on the 19th Oct. 1900 by Hosp. Asst. Khudabakhsh, transferred from gen. duty, Delhi.

Asst. Surgn. Hari Chand resumed ch. of the Civil Hosp., Ludhiana, on the 10th Nov. 1900, relieving Asst. Surgn. Udal Bhan, Imperial List.

Hosp. Asst. Jai Singh, at present serving in the Milly. Dept., is entitled to the higher rate of pay of his grade from the 1st Oct. 1900.

Asst. Surgn. Mehta Harnam Datta was apptd. to do gen. duty at the Mayo Hosp., Lahore, from the 5th Sept. 1900.

Asst. Surgn. Mehta Harnam Datta, doing gen. duty at the Mayo Hosp., Lahore, was apptd. Junior House Surgn., Mayo Hosp., Lahore, from the 11th Sept. 1900, relieving Asst. Surgn. Mir Hidayat Ullah.

Lieut. E. J. O'Meara, I. M. S., made over ch. of the duties of Supdt. of the Jhelum Jail to Asst. Surgn. Yakub Beg on the 20th Oct. 1900.

Asst. Surgn. Yakub Beg made over ch. of the duties of Supdt. of the Jhelum Jail to Capt. C. J. B. Milne, I. M. S., on the 22nd Oct. 1900.

Asst. Surgn. Har Narain held ch. of the current duties of the office of Supdt. of the Hoshiarpur Jail from the 24th to 30th Oct. 1900, both days inclusive, during the absence of Dr. D. N. P. Datta, M.D., Uncovenanted Med. Offr., on insp. duty in the dist.

Capt. C. J. B. Milne, I. M. S., made over ch. of the duties of Supdt. of the Jhelum Jail to Major D. T. Lane, M.D., I. M. S., on the 5th Nov. 1900.

Asst. Surgn. Mirza Yakub Beg, in ch. of the Jhelum Dispy., officiated as Civil Surgn. of that stn., in addn. to his own duties, from the 20th to the 22nd Oct. 1900, vice Lieut. E. J. O'Meara, I. M. S.

Capt. C. J. B. Milne, I. M. S., assumed ch. of the civil med. duties of Jhelum on the 22nd Oct. 1900, relieving Asst. Surgn. Mirza Yakub Beg.

On return from Murree, Major D. T. Lane, I. M. S., assumed ch. of the office of Civil Surgn., Jhelum, on the 5th Nov. 1900, relieving Capt. C. J. B. Milne, I. M. S.

Hosp. Asst. Lal Singh, doing gen. duty at Murree, Rawalpindi Dist., was apptd. to the ch. of the Kalanaur Dispy., Gurdaspur Dist., on the 30th Nov. 1900, relieving Hosp. Asst. Gandu Ram, who was placed on gen. duty in the Gurdaspur Dist.

Hosp. Asst. Baber Khan, doing gen. duty at Amritsar, was apptd. as a temp. arrangement, to the ch. of the Mayo Salt Mines Dispy., Khewra, Jhelum Dist., on the 3rd Nov. 1900, during the absence of Asst. Surgn. Narain Singh to attend the Septennial Prof. Exam. of Asst. Surgns. at Lahore.

On return from Lahore, Asst. Surgn. Narain Singh rejoined the Khewra Dispy. on the 8th Nov. 1900, relieving Hosp. Asst. Baber Khan.

Hosp. Asst. Ram Chand, Rawalpindi City Dispy., obtained two months' privilege leave and was relieved of his duties on the 1st Dec. 1900 by Hosp. Asst. Jaggan Nath, transferred from Attock, Hazara Dist.

DOMESTIC OCCURRENCES.

[The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.]

BIRTH.

NEILSON.—At Sirdarpore, Central India, on the 7th December, the wife of W. H. Neilson, M.B., Major, I. M. S., of a daughter.

MARRIAGE.

CALVERT—MARGETTS.—At St. Paul's Cathedral, Calcutta, on 15th December, by Canon Luckman, Capt. J. T. Calvert, M.B. (Lond.), I. M. S., second son of J. M. Calvert, Esq., of Roehdale, Lancashire, to Ethel Blanche, only daughter of the late W. G. Margetts, of Rochester, Kent.

DEATH.

CURRIE.—On the 3rd December 1900, at 27, Eastbourne Terrace, Hyde Park, W., Surgeon-General George Vernon Currie, I. M. S., late 10th Bengal Lancers, son of the late Physician-in-Chief Claude Currie, I. M. S., aged 72.

ORIGINAL ARTICLES.**SOME PRACTICAL NOTES ON THE BACTERIOLOGICAL DIAGNOSIS OF HUMAN PLAGUE (PESTIS HOMINIS).^{*}**

By SHERIDAN DELEPINE, M.D.,

Procter Professor of Pathology, Owen's College, Manchester.

THE following remarks are based on experiments carried out in my laboratory with a culture of bacillus pestis kindly given to me by Dr. CALMETTE in April last. This culture was used chiefly for the purpose of repeating experiments of previous observers, YERSIN and KITASATO more especially. The culture had been obtained by Dr. CALMETTE from a case of plague in Oporto (1899), and was so virulent in April last that it was sufficient to prick the skin of a guinea-pig with a needle loaded with bacilli to produce an attack of the disease fatal in about five days. Dr. CALMETTE also gave me very valuable information in a most generous manner, and I take this opportunity of thanking him cordially.

Through the courtesy of Dr. BROWNLEE and Dr. M'CLURE I was able to examine 29 of the cases of plague under treatment in the Glasgow Fever Hospital. Medical men have much reason to be grateful to these gentlemen for the very unselfish way in which they sacrificed for the benefit of their colleagues much of the time they could so ill afford to spare.

I have also to acknowledge the kindness of Dr. BUCHANAN, who supplied me with *post-mortem* material from three of the fatal cases which had then occurred in Glasgow.

THE DISCOVERY OF THE BACILLUS.

It is unnecessary in a communication of this kind to give a systematic account of the bacteriology of plague,¹ as numerous summaries of the subject have appeared of late. Suffice it to say that in 1894 KITASATO and YERSIN, working independently in Hong-Kong, each isolated a bacillus from the buboes and blood of patients affected with bubonic plague, from the organs of rats and mice which had died of plague, from the dust (KITASATO) and from the soil (YERSIN) of houses where patients had died of plague. In addition, they had shown that the bacillus could be easily cultivated outside the body, that the disease could be produced experimentally in the lower animals by inoculation, and by feeding on cultures of the bacillus or on organs containing the plague bacillus. YERSIN had also shown that flies might be infected, and become a source of spread of the disease.

The descriptions given by YERSIN and KITASATO were very similar, but they disagreed with regard to certain points as to the distribution of the bacillus. Thus KITASATO recognised the bacillus more constantly in the blood than did YERSIN, who found it specially in severe cases. KITASATO is also of opinion that the plague microbe may be stained by GRAM's method, and causes the coagulation of milk, which is not in agreement with the results obtained

by other observers. It is, however, impossible to believe that KITASATO could have examined a number of typical cases of plague without seeing the same organism as that seen by YERSIN, for when an unsoftened bubo is examined, the bacillus is usually found in great abundance and in a state of purity. From a diagnostic point of view the most important addition which has been made to the discoveries already maintained is due to CHILDE, who in 1896 established the existence of plague pneumonia by the bacteriological examination of sputa.

Another advance useful in diagnosis was made by the discovery that plague could be produced experimentally by painting the conjunctival mucous membrane with products containing the plague bacillus, as recommended by the Bombay German Commission, or by painting the nostrils of guinea-pigs, rabbits, or monkeys, according to the method introduced by ROUX in 1898.

Finally, I should also mention the attempts which have been made to utilise the serum reaction for diagnostic purposes (WYSSKOWICZ and ZABOLOTNY, and others.)

TYPES OR VARIETIES OF PLAGUE.

It is important, from a diagnostic point of view, to be familiar with the various forms which the disease may assume. Like some other observers, I have been able to reproduce these types experimentally in the guinea-pig with the virulent culture I had at my disposal (obtained by Dr. CALMETTE from one of the cases in Oporto). These varieties depend (1) on the channel of entrance; (2) the virulence; (3) the quantity of the bacilli.

I.—THE BUBONIC TYPE.

The bubonic type is produced in the guinea-pig by infecting slight cutaneous wounds with a virulent culture of the bacillus (or by injecting subcutaneously various quantities of an attenuated culture). After slightly scarifying the skin on the inner side of one of the hind legs of a guinea-pig, I rubbed the part with a loopful of a moderately virulent agar culture of bacillus pestis. Signs of disease became evident at the end of twenty-four hours, and the animal died about five and a half days (138 hours) after inoculation. After death considerable oedema was found near the seat of inoculation in the corresponding groin, and to a lesser extent over the posterior half of the abdomen. The ooplial and superficial inguinal glands were much enlarged and suppurating, the corresponding lumbar glands were also enlarged and deeply congested. The spleen was enlarged and full of very minute tuberculous-looking lesions (these contained a very large number of plague bacilli). The liver was large and unequally congested. The lungs were intensely congested, and contained eight or ten large tuberculous-looking masses, situated chiefly under the pleura. These pseudo tubercles were surrounded by a wide zone of deeply congested, partly hemorrhagic tissue (secondary plague pneumonia). All these lesions resembled those produced in the guinea-pig by the bacillus mallei. The right side of the heart was much distended with dark blood. Most of the lymphatic ganglia, other than those already mentioned, were swollen and more or less congested. Typical plague bacilli were demonstrated by microscopical examination in suppurating inguinal glands and the oedematous tissues

^{*}(Extracts from an Address delivered on the occasion of a demonstration given to the Pathological Society of Manchester, and sent to the *Record* for publication.

round them—the spleen, liver, lungs, and blood of the heart. They were most abundant on the spleen and glands. Cultures revealed, in addition to the plague bacillus, the presence of the staphylococcus pyogenes aureus in the inguinal glands, but not in the other organs. There were only two colonies of staphylococci amongst a very large number of colonies of the plague bacillus. In one of the agar cultures they were also present in the bouillon cultures. Animals inoculated with these impure cultures all died of plague, but in all their organs the plague bacillus and the staphylococcus were found together, the staphylococcus having apparently multiplied more rapidly than the plague bacillus. Judging by the relative number of colonies obtained, the spread of staphylococcus had been favoured by the presence of the plague bacillus, but the disease produced by the mixed infection had all characters of plague.

II.—SEPTICÆMIC PLAGUE.

This was produced by injecting the bacillus under the skin. One-sixth of an agar culture of a slightly attenuated type, which had been kept in the laboratory for about six months, injected deeply into the thigh, produced the death of a guinea-pig in sixty-six hours. With an agar culture isolated seven days previously from a rapidly fatal case, $\frac{1}{10}$ th of the culture was fatal in less than forty-eight hours. One mouse was killed in less than twenty-four hours by $\frac{1}{10}$ th, and another in forty-five hours by $\frac{1}{10}$ th part of the same culture. All these cases differed from the first case described, in that the enlargement of the glands near the seat of inoculation, though distinct, was less marked; these glands were of a deep red colour and firm. Nearly all the other lymphatic glands were deeply congested. The spleen was large in all cases, but showed no tuberculous-looking lesions, the lungs were either congested or pale, but generally œdematous. The local œdema was variable, very extensive and hæmorrhagic in one case, but comparatively slight in the others. In all these cases the bacillus was found abundantly in the blood of the heart, spleen, liver, and lymphatic glands.

III.—PULMONARY PLAGUE.

This was produced according to ROUX's method by applying the bacilli with a small, soft, camel-hair brush to the nostrils of guinea-pigs. In one case I used an agar culture which had been kept for nearly five months in a cupboard at the temperature of the laboratory. For another case I selected an agar culture I had isolated nine days previously from a fatal case. In both cases there was evidence of general discomfort before the end of the third day, and both animals died between the fifth and sixth day after the painting of the nostrils.

There was considerable swelling of the integuments round the nostrils and of the upper lip; the trachea contained mucopurulent exudation, slightly tinged with blood in one case. In both cases the lungs were large, œdematous, generally pale, their surface was slightly uneven owing to collapse of small portions of parenchyma immediately under the pleura; there were also small ecchymoses under the pleura, and in one case several larger hæmorrhagic foci. There was, in fact, well-marked disseminated broncho-pneumonia, and the bronchial and cervical lymphatic ganglia were intensely congested.

Some of the cervical glands contained hæmorrhagic foci; these were almost black; the most affected glands were surrounded by œdematous blood-stained connective tissue. The other organs presented the same appearances as in septicæmic cases. Plague bacilli were easily demonstrated in the tracheal mucus, the lungs, the blood of the heart, the cervical glands, and the spleen. The most interesting feature of plague pneumonia is that it can be produced with bacilli, the virulence of which is so attenuated that they do not produce the disease by subcutaneous inoculation.²

IV.—GASTRO-INTESTINAL FORM.

This was introduced in some mice, of which I placed two in a cage which had been occupied by two guinea-pigs that had died of plague, and two others in a clean cage, their food being mixed with some of the excreta of a guinea-pig also dead of plague. The first two mice died in about ninety-six hours; the last two died in about seventy-two hours. They all seemed to have succumbed to some mixed form of infection; I could recover the bacillus in one case only.

The experiments of YERSIN and KITASATO showed from the first that infection could be produced by ingestion of infectious products. KITASATO was even able to find the plague bacillus in the contents of the intestine.

It is sometimes argued that animals fed on material containing plague bacillus are not infected through the alimentary tract, but through the nose and air passages. BATZAROF has, however, produced the disease by depositing in the mouths of guinea-pigs portions of infected organs, care being taken that the nostrils were not contaminated, or the buccal mucous membrane wounded.

A gastro-intestinal form of plague is not usually recognised as a clinical form of human plague.

V.—CUTANEOUS FORM.

I have not been able yet to produce localised cutaneous lesions, not followed by lymphatic extension, giving rise to the bubonic type of the disease. It is said that in the human subject pustules may occasionally occur without formation of buboes. The contents of such pustules are said to be rich in bacilli. Usually, however, infection through the skin is followed by the production of buboes, and in such cases it is not always possible to recognise any cutaneous lesion at the primary seat of infection.

From the preceding short summary, it will be seen that the three chief types of human plague—that is, the bubonic, the pulmonary, and the septicæmic—correspond to three types of infection, the first two being determined by the channel of infection, the last being capable of arising whenever the resistance of the tissues is considerably reduced, or the virulence or quantity of the bacilli very great. It will be noticed that in all cases the lymphatic glands are liable to be affected, but that typical inguinal and axillary buboes are produced chiefly in connection with cutaneous infection of the extremities, whilst cervical buboes may be produced as a result of infection of the skin of the head and neck, or of the nasal or buccal mucous membranes. In the case of infection through the air passages the most characteristic bacteriological feature is the presence of plague bacilli in the bronchial and nasal discharges. Finally, in the rapidly

fatal forms, without any marked localisation of lesions, the blood contains a large number of bacilli. In the experiments recorded above, the blood was invariably found to contain bacilli easily demonstrable by direct microscopical examination and cultivation, whatever mode of infection had been adopted. In the cases of mixed infection which I produced artificially, the plague bacillus could be easily separated from the associated cocci.

DIAGNOSIS OF PLAGUE BY EXPERIMENTAL INFECTION.

Two methods of infection may be used for diagnostic purposes—

1. *Subcutaneous inoculation*, for which mice and guinea-pigs are especially suitable.

2. *Infection through the air passages*, obtained by painting the nostrils with the products under investigation. This method is specially suitable when products of low virulence are under investigation—as, for instance, the pus of suppurating buboes. (In suppurating buboes the plague bacilli, when found, are usually in a state of degeneration and frequently of low virulence.) For this method of experimental infection the guinea-pig is specially suitable.

MICROSCOPICAL EXAMINATION.

I have described the experimental methods in order to make clear the distribution of the bacillus. In practice, however, the first steps to be taken would be to make a microscopical examination—

1. Of material obtained from a bubo or from the oedematous tissue surrounding it.
2. Of blood obtained from the tip of a finger or from the lobe of the ear.
3. Of the expectoration in suspicious cases of pneumonia.

In ordinary cases such an examination presents no difficulty, and can be carried out very rapidly. Almost any of the aniline dyes in common use can be used for the purpose of staining cover-glass preparations of material obtained with the hypodermic syringe from buboes or their neighbourhood. Freshly-prepared aqueous solutions of methyl violet, aqueous solutions of methylene blue, or LOEFFLER'S blue may be used. Carbol-thionin blue or diluted carbol fuchsin have given me the best results. Carbol fuchsin has, however, a tendency to stain too deeply the degenerated cells and products among which the bacilli are found; and to obtain good preparations showing well the bipolar stain of the bacillus, I treat the film for about five seconds with 15 per cent. solution of sulphuric acid, which is washed off rapidly; carbol fuchsin is then dropped on the film; after a contact not exceeding two or three seconds, the stain is thoroughly washed off. The bacilli do not stain by GRAM'S method, but a little of the material surrounding them remains slightly stained.

CULTIVATION OF THE BACILLUS.

This presents usually no difficulty, except in the case of sputa. Ordinary alkaline peptone bouillon agar seems to me the best medium to use in ordinary cases, at any rate I have not found that with the blood or tissues of animals affected with plague it was possible to obtain typical cultures more rapidly on any other medium. On agar at the temperature of the body minute colonies are already visible eight or ten hours after inoculation of the medium.

Neither blood serum, glycerine agar, nor gelatine agar present any advantage. (In separating the plague bacillus from other microbes in sputum, advantage may be taken of the fact that the plague bacillus grows quicker at a low temperature than other pathogenic bacteria; this method of cultivation has been recommended to me by Dr. CALMETTE.) Growth is also rapid in ordinary alkaline peptone bouillon; if care be taken not to disturb the bouillon, the growth in that medium is characteristic, bacillus grows near the surface, and adheres to the sides of the tube, near the surface of the fluid, forming a whitish flocculent ring. The fluid remains clear so long as the fluid is not disturbed, but the slightest motion causes flakes of bacilli to fall, and for a time the fluid seems cloudy; this probably accounts for the turbidity noticed by KITASATO. The production of involution forms by cultivation on salted agar, as recommended by HANKIN and LEHMANN, is not always sufficiently rapid to be very helpful when rapid diagnosis is wanted. The same objection may be offered to HAFKINE'S method of cultivation on buttered bouillon; the appearances of stalactite culture are, however, very striking. I have not found that milk was coagulated by this bacillus.

PRECAUTIONS AGAINST LABORATORY PLAGUE.

I cannot conclude these very cursory remarks on the bacteriological diagnosis of plague without pointing out the dangers of the slightest carelessness in such work.

Animals under observation should be kept in a separate room, in glass jars covered with fine gauze weighted lids. For additional security the jars should be placed in a larger case, constructed very much like a meat safe, but entirely made of metal and glass (iron frame, sides entirely closed by fine wire gauze, glass doors, with well-fitting frame.) This outer case should entirely prevent rats, mice, or even insects, from having access to the animals or their food.

As a further precaution, this case should be placed above a large metal tray easily disinfected, and supported above the floor by a metallic stand. These precautions are necessary to prevent accidental infection of rats and mice, and of various parasites which usually find their way wherever animals are kept.

The skin of animals which have to be dissected should be well soaked with an acid solution of perchloride of mercury (1 in 500) before the animal is opened, and the dissection should be made over a tray containing some of the same solution. The body and organs which are not preserved in suitable preservative fluids should at once be destroyed by fire. Laboratory attendants should not be allowed to touch any infected animal or products before these have been thoroughly disinfected. The bacteriologist may take the risks of his own work, and being well acquainted with them, is in a position to avoid them, at any rate it is his duty to face them; the case is not the same with regard to his assistants, and more especially to those that are young and untrained. The comparatively great number of deaths attributable to plague infection in the laboratory or the *post-mortem* room, which have occurred during the last three or four years, clearly indicates that an exceptional amount of care is needed in work of this kind.

In these short notes I have not attempted to give a complete account of methods; I have simply tried to give such information as is not already easily accessible to all through the many excellent summaries of the subject which have appeared of late.

1 An excellent review of the subject will be found in Netter's short but masterly treatise on *La Peste et son Microbe*, Paris, 1900.

2 Batzaroff *Annales de l'Institut Pasteur*, 1899, p. 286.

DISEASE OF THE FALLOPIAN TUBES, WITH SPECIAL REFERENCE TO SPECIFIC INFECTION.*

By J. R. GUTHRIE, M.D.,
Dubuque, Ia.

No structure of equal pathological interest and of such vital clinical importance to the medical profession was so long and so persistently neglected as the fallopian tube. In the older medical literature it received only the briefest mention, and then the reference was most superficial. Little attention was given its anatomy or physiology, while its histology was wholly neglected. Nothing was known of its pathology, and no symptoms were attributed to diseases of this important structure. What a marvellous development in pathological interest and clinical importance during recent years! Careful research will disclose the fact that generations ago the clinicians described disease in the fallopian tube, but through lack of both anatomical and pathological precision their teaching made practically no modification in either the medical thought or practice of the day.

Perhaps the first well-authenticated account of a discussion of the fallopian tube and its diseases was in the year 1665, and may be well epitomized in this statement "that occlusion of the tube is one of the most fruitful causes of sterility." Nearly a century later, in 1742, JOHANN WEITBRECHT, the great anatomist of St. Petersburg, described the obliteration of the tube in a woman with one child and who was subsequently sterile. In 1766 ASTNIC gave considerable attention to the fallopian tube, and afforded perhaps the first accurate description of its diseases. He clearly describes hydrosalpinx, pyosalpinx and tubal pregnancy. But, as frequently happens, his teachings seemed for a time to be forgotten, or at least neglected. Nothing new on this subject is found in medical literature for nearly a century. In the writings of that able French observer, COLUMBAT, as translated by CHARLES D. MEIGS in 1845, there is found only a brief mention of this organ, and he practically describes only one disorder of the tube—atrophia. Investigation was imperfect, reports contradictory, and knowledge of slow growth.

In 1854 CHARLES D. MEIGS published his brilliant work. He likewise refers to atresia of the tube and to its effect in producing sterility. He speaks of a most remarkable death from what would to-day be diagnosed as a case of pyosalpinx. Acute observer that he was, scholarly and progressive in his field, yet he devoted only five pages to the tube, including its anatomy, physiology, pathology, clinical history and methods of treatment. T. GAILLARD THOMAS published his work on diseases of women in 1869. He was a bright light in his special field for nearly a generation, and yet he gives only two pages to a discussion of the tube and its diseases. In brief, an examination of older medical works and journals of all kinds, home and foreign, will show absolute want of literature on this important subject.

The medical man of to-day is well informed on all phases of disease of the tube and of the different views of tubal disease, its origin, pathology and methods of

treatment. The causes of inflammation are numerous. When the tube is considered as a continuation of the structure of the uterus, the cause of the inflammation is easily understood. Any cause which may produce inflammation of the uterine structure may, by simple extension, cause an inflamed tube. Disease of bacterial origin may readily affect the contiguous structure. Among the exciting causes are those producing endometritis or metritis, direct injury, sudden checking of the flow, pelvic hyperæmia, infection with staphylococcus streptococcus and gonococcus. Of these causes, gonococcus infection is most frequent and important.

Authorities differ widely as to the importance of the gonococcus as an etiologic element in production of tubal diseases. The question regarding this feature is important and difficult to determine. All will agree that the gonococcus is a frequent cause and should demand most earnest attention, and that the profession must be alive to prevent a trouble which, when established, we are so powerless to cure. We all too often meet cases like the following: Young lady of good family and personal history, with menstruation regular and painless, who marries; wedding trip is taken, and the bride returns home an invalid. She suffers from pelvic distress, and all the usual symptoms of specific infection are plainly evident.

A latent gleet in the male may be the cause of a fresh infection in the mucous membrane of the vagina. There is much speculation in regard to the gonococcus of NEISSER as to its possible origin, the manner of its acquiring specific functions, how it may be possible by culture methods to rob it of its specific character, etc. The infectious character of the germ and its peculiar action on mucous membrane is as yet imperfectly understood. The germ is cultivated in laboratory and changed from media to media until it is theoretically sterile; yet, deposited on mucous membrane, its growth is luxuriant. Only a few germs may be present, yet the development is of almost incredible rapidity. A woman with latent gonorrhœa for years imparts a virulent ophthalmia to her new-born child. This organism has a wondrous grasp upon life, so wondrous, in fact, that one is almost ready to accept the doctrine of NOEGGERATH, "once infected, always infected;" at least one is ready to accept this as a safer rule than that gonorrhœa is no more to be thought of than a common cold. Practical experience and bacteriologic research agree that the gonococcus is tenacious of life in the human tissues.

BUMM transplanted the twentieth generation into healthy mucous membrane and produced a virulent gonorrhœa. WARREN states that suppurative inflammation of the tube is largely due to the gonococcus. BERNUTZ's investigation coincides in the opinion. The findings of NOEGGERATH and SANGER are along the line—the two latter find pyosalpinx in 38 per cent. of women suffering from gonorrhœal infection.

GOEL, after an extensive research, says he was able to discover the gonococcus after a latency of six years. NEISSER in 143 cases, extending over a period varying from two months to eight years, found the germ in 80 cases. The observation of WERTHEIM is in the same direction. He reports the finding of the gonococcus in a chronic salpingitis of two years' duration. NEISSER

* Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., and sent specially to the *Record* for publication.

insists upon the value of microscopic examinations, and makes a strong point of the necessity of frequent tests. Some observers failing in this have much under-estimated the frequency of gonorrhoeal infection in diseases of the tube. One must not be satisfied with one or two examinations, but must insist upon repeated careful tests, and the perseverance will frequently be rewarded by the establishment of a positive diagnosis. The failure of some observers to frequently discover this germ in tubal disease is to be attributed to either faulty methods or a lack of perseverance in making investigations. While this germ is practically unlimited as to time, it is very circumscribed as to tissue invaded. It is limited to usually the epithelial layer. That it may occasionally affect the deeper tissues is denied, yet this is undoubtedly very rare. The cervix stands second in point of the pregnancy of infection and first as to chronicity. By simple extension the tube becomes diseased. The gonococcus finds the epithelial layer of the mucous membrane its favorite habitat, and here multiplies, with unaccountable rapidity. There its irritating effect soon becomes manifest in increased blood-supply, oedema, and an enormous leucocytic exudate, followed by round-cell infiltration. This infection may lead to a simple salpingitis or to suppurative disease of the tube, depending on the virulence of the germ and the antimicrobial power of the tissues. There are various modes of infection—sexual intercourse, infection by use of douche tubes, by the careless use of gynecological instruments and by carelessness in making examinations. Has sufficient emphasis been placed on this as a cause of pyosalpinx, confessedly a most serious condition? Has the profession made clear and positive its position in regard to the baneful far-reaching effect of this infection on the health and life of the women of our land?

This is a serious question, and one not to be pushed lightly aside, but demands our careful attention. That the profession has not fully appreciated the serious far-reaching effect of this infection I fully believe. As one of the results of this apathy and indifference, is it any wonder that the laity regard gonorrhoea as a trivial affection? At the meeting of this Association at Columbus, Ohio, a committee was appointed to investigate and report on ravages produced by syphilis on women; a similar committee should be appointed to investigate and report on the baneful effects of gonorrhoea on the female. While syphilis slays its thousands, gonorrhoea slays its tens of thousands. When fully impressed with its true character, the conscientious physician will do all in his power to prevent a trouble which, when fully established, he is powerless to cure. Prevention is the glory of modern medicine—certainly here is a fruitful field for its exercise.

I am convinced that the profession is not impressed with the magnitude of this evil, yet the truth is taught with more or less clearness by leading American authorities. KELLY, GARRIGUES, PENROSE, BALDY, PRICE, SKENE, DUDLY and HENROTIN mention the gonococcus as an important agent in pyosalpinx. I have had correspondence with a large number of physicians of Iowa and adjacent States, and find there is considerable diversity of

opinion; yet the majority place the gonococcus as an important agent in pyosalpinx. From facts collected from fifteen of the chief cities of Iowa, I find 70 per cent. the average estimate of the cases of tubal disease due to gonorrhoea. From correspondence with physicians in small towns and rural districts, I learn of the infrequency of tubal disease in females. An examination of the records of three hospitals doing a good share of work shows a large number of cases of suppurative disease of tube of specific origin. Individual experience is only of value in determining a proper understanding of this question. In my experience during the last year I find 80 per cent. of the cases due to specific infection.

I am of the opinion, therefore, that the importance of gonorrhoea in causing tubal disease has not been properly emphasized; that the question is a serious one and worthy of our careful investigation; and that, as earnest physicians imbued with the idea of prevention, we should make ourselves felt in behalf of these unfortunate sufferers.

CONTAGION: ITS MEANING AND ITS LIMITATIONS.*

BY LAWRENCE FLICK, M.D.,
Philadelphia, U. S. A.

THERE is perhaps no question in medicine upon which the profession is so much at sea as that of contagion. There has been so much quibbling about the meaning of the word contagious, and so many hairsplitting distinctions made between it and the word infectious, that the general reader of medical literature has become bewildered and is really at a loss to know, when he encounters the words, what is actually meant by them. It may be well, therefore, to again take soundings upon the entire subject, and to seek the channels of thought which can be used by all of us, so as to again bring our observations within reach of common intelligence.

The word contagion is derived from the Latin word *contingere*, which means to be in contact with, to touch. As applied to disease it conveys the idea of communicability from one person to another, from a human being to an animal, from an animal to a human being, or from one animal to another, by contact, without an intermediate agency or host. The Century Dictionary defines it as follows:—"First, infectious contact or communication; specifically and commonly the communication of disease from one person or brute to another. A distinction between contagion and infection is sometimes adopted, the former being limited to the transmission of a disease by actual contact of the diseased part with a healthy absorbent or abraded surface, and the latter to transmission through the atmosphere by floating germs or miasmata. There are, however, cases of transmission which do not fall under either of these divisions, and there are some which fall under both. In common use no precise discrimination of the words is attempted." WEBSTER, in defining the word contagion, quotes from DUNGLISON as follows: "The act or process of transmitting a disease from one person to another by direct or indirect contact." For a second definition he gives

* Read before the Philadelphia County Medical Society, 14th December 1899, and sent to the *Record* for publication.

"That, which serves as a medium or agency to transmit disease; pestilential influence." In illustration of this meaning, he quotes from SHAKESPEARE the following lines: "And will he steal out of his wholesome bed to dare the vile contagion of the night." In his definition of the word contagious he says: "First (Med.), communicable by contact: catching: as a contagious disease; second, containing or generating contagion: pestilential: as contagious air; third, spreading or communicable from one to another." Under synonyms he says: "Contagious, infectious. These words have been used in very diverse senses; but in general a contagious disease has been considered as one which is caught from another by contact, by the breath, by bodily effluvia, and so on; while an infectious disease supposes some entirely different cause acting by a hidden influence, like the miasma of prison ships, of marshes, and so on, affecting the system with disease. This distinction, though not universally admitted by medical men as to the literal meaning of the words, certainly applies to them in their figurative use. Thus we speak of the contagious influence of evil associates; the contagion of bad example; the contagion of fear, and so on, when we refer to transmission by proximity or contact. On the other hand, we speak of infection by bad principles, and so on, when we consider anything as diffused abroad by some hidden influence." GOULD, in his Medical Dictionary, defines contagion as "the process by which a specific disease is communicated between persons either by direct contact or by means of an intermediate agent." Infection he defines as "the communication of disease germs or virus by any means, direct or indirect." THOMAS' Medical Dictionary gives the definition of contagion as "the communication of a disease by contact or by inhaling the effluvia from one already affected; often used as synonymous with infection." Infection he defines as "the communication of a disease by personal contact with the sick, or by means of effluvia arising from the body of the sick, contagion. The transmission of disease from one individual to another of a different class. The term is sometimes used as synonymous with the contagion or agent by which a communicable disease is conveyed." The word infectious he defines as "contagious; corrupting; that may be easily communicated; capable of transmission from one person to another by contact or by being conveyed through the atmosphere." The word contagious he defines as "a term applied to diseases which are spread by contagion or communicated." In DUNGLISON'S Medical Dictionary the word contagion is defined as "transmission of a disease from one person to another by direct or indirect contact. Also at one time applied to the action of miasmata arising from dead animal and vegetable matter, bogs, fens, etc. Contagious diseases are produced either by virus or contagion capable of causing them by inoculation, as in small-pox, cow-pox, hydrophobia, syphilis, etc., or by miasmata proceeding from a sick individual, as in plague, typhus gravior, measles, etc. Contagion and infection are generally esteemed synonymous. Frequently, however, the former is applied to diseases not produced by contact, as measles, etc., while infection is used for those that require positive contact, as itch, syphilis, etc. Diseases which are only produced by con-

tagion are said to have their origin in specific contagion, as small-pox, cow-pox, syphilis, etc. Those produced by contagion, and yet supposed to be sometimes owing to other causes, are said to arise from common contagion, as typhus, cynanchoe, protidea, etc." The definitions given in the dictionaries are somewhat obscure, and all savor of old-time ideas about the etiology of disease. All, however, agree on certain points, namely: First, that the word contagion has a broader meaning than the word infection; and secondly, that the words contagion and infection may be used synonymously. In current literature we frequently find the position of the two words reversed, and a limited meaning given to the word contagion and a broad meaning to the word infection. *

The word infection is derived from the two Latin words *in* and *facere*, which mean to carry in something, to make in something. As originally applied, the word meant the carrying of disease from one person to another by a force extraneous to both the disease and the persons giving and receiving the disease. It was principally used to convey the thought that diseases which had their source in miasmatic conditions were wafted by the air, and thus communicated to all persons breathing that air: for example, as malaria was carried by the wind from swamps. It had a shade of meaning which well suited certain diseases to which the word contagious could not properly be applied.

In the light of the germ-theory of disease, we are in a much better position to formulate a clear-cut idea of what is meant by contagion, and wherein contagion differs from infection. We see by it that the key to the true application of the two words is really to be found in their literal meaning and original application. In the adjective form, other synonyms of contagion are: Communicable and catching. Communicable and catching are generic terms, and convey the broad idea of communicability without any modification as to method or process by which the end is accomplished. Contagion and infection are specific terms, and convey modified ideas of communicability, each peculiar to itself. Contagion conveys the idea of communicability by contact, direct or indirect; the chain of communication between the person having the disease and the person receiving it being unbroken. Infection conveys the idea of communicability through an intermediate agency outside of both the person who has the disease and the person to whom the disease is conveyed. The essential features of a contagious disease are:—

- (1) A living organism, the parasitic existence of which in a human being or animal creates a disease.
- (2) The communicability of that organism from one human being to another, from a human being to an animal, from an animal to a human being, or from one animal to another.
- (3) Immediate or mediate contact between a person or animal suffering from the disease, and a person or animal free from it.
- (4) A limited environment, under which communicability is operative.

The essential features of an infectious disease are :—

(1) A living organism, the parasitic existence of which in a human being or animal creates a disease.

(2) The communicability of that organism to human beings and animals.

(3) An intermediate agency, through which communicability between two hosts, or from a non-parasitic habitat to a host, can be established.

The difference between the ideas of contagion and infection is :—

(1) That, in contagion, the chain of contact between the person giving off the disease and the person receiving it must be complete and unbroken, whilst in infection the chain of contact may be broken by an intermediate agency, or host.

(2) That, in contagion, the environment, under which communicability is operative, is limited ; whilst in infection the environment, under which communicability is operative, is general.

It is true that, in contagion, the contact may be mediate, that is, through fomites, and that fomites in a sense constitute an intermediate agency ; but fomites differ on important points from the intermediate agency of infection. The intermediate agencies of infection usually are earth, air, and water. Fomites cannot become a soil for the reproduction of organisms which produce contagious diseases, and have no inherent power of transferring them from one host to another. They can only give them shelter until some extraneous force conveys them into the proximity of a prospective host, or until chance brings such a host into their vicinity. The intermediate agency of infection, on the other hand, can become a soil for the reproduction of the organisms which produce infectious diseases, and may possess inherent forces with which to convey such organisms to prospective hosts.

In the category of contagious diseases I would place small-pox, measles, scarlet fever, roseola, influenza, colds of various kinds, tonsillitis, chicken-pox, whooping-cough, mumps, typhus fever, diphtheria, plague, tuberculosis, leprosy, syphilis, erysipelas, glanders, gonorrhœa, septicæmia, parasitic skin diseases and contagious conjunctivitis.

In the category of infectious diseases I would place cholera, typhoid fever, the malarial fevers, yellow-fever, dengue, tetanus, and, possibly, pneumonia and cancer.

That all of the diseases here enumerated are communicable can scarcely be doubted in the present light of medical science. It has not yet been demonstrated in all that a living organism is the active and essential cause ; but we can deduce by analogy from those in which a living organism has been found to be the active cause to those in which no organism has as yet been identified as the active cause, that a living organism must be the active and essential cause in all. Small-pox, measles, scarlet fever, roseola, chicken-pox, whooping-cough, mumps, typhus fever, diphtheria, plague, syphilis, erysipelas, glanders, gonorrhœa, septicæmia, parasitic skin diseases, contagious conjunctivitis, cholera, typhoid fever, yellow-fever and dengue are admittedly communicable, upon clinical evidence alone. In tuberculosis, diphtheria, erysipelas, gonorrhœa, septicæmia, cholera and typhoid

fever, the organism which produces these diseases has undoubtedly been identified. A living organism as an active cause having been discovered in these, some of which are admittedly contagious, it may be logically assumed that a similar living organism as an active cause must exist in the others. Like causes produce like effects, and like effects must have like causes. Pursuing this line of thought to its logical conclusion, we arrive at the proposition that communicability is predicated upon life, and that all diseases which are found to be due to living organisms are consequently communicable. What can thus be reasoned out has already been worked out in all detail in the laboratory. In diphtheria and tuberculosis, not only have the organisms which produce these diseases been discovered, but every step in the process of communicability has been demonstrated. In one of these, diphtheria, the clinical evidence has been in favor of communicability ; in the other, tuberculosis, the clinical evidence, as usually interpreted, has generally been against communicability. In both, however, the same fundamental law has been found to exist, namely, that they are due to living organisms, and that those organisms are communicated from one host to another under certain well-fixed laws and conditions. It is from the knowledge that we have gathered about tuberculosis and other diseases in the laboratory, together with the clinical knowledge that we possess about these and other diseases, that we are justified in placing diseases in the category of communicable diseases which have not yet been demonstrated to belong there, either at the bedside or in the laboratory.

Into which category a communicable disease should be placed, whether that of contagious or infectious, must for the present remain, to a very great degree, a matter of conjecture. When the organisms which produce the different diseases have all been identified, and their life-histories studied, it can be done with mathematical accuracy. For the present, the order in which I have placed them seems to me to correctly represent our knowledge about them as gleaned at the bedside and in the laboratory. Small-pox is a typically contagious disease ; malarial fevers are typical infectious diseases. Between these there are shadings in both directions. If we bear in mind, however, the essential features of contagion and infection, and the essential difference between them, as shown us by the typical diseases representing them, we cannot go far astray in placing all communicable diseases where they belong. I have placed pneumonia and cancer among the infectious diseases rather than among the contagious, for the reason that the environment under which communicability is operative seems to be general instead of circumscribed. When pneumonia is prevalent in a community, it seems to strike down people in all quarters, irrespective of contact ; and cancer seems to be distributed evenly among all classes and in all parts of a community.

A most important point in the question of contagion is that of limitation. Whilst there are certain laws to which all contagious diseases subscribe, every contagious disease has laws to which it alone is amenable. These laws are dependent upon the idiosyncrasies of the organisms producing the diseases, and upon the soil

which the organisms require for their development and the completion of their cycles of life. For example, whilst small-pox and tuberculosis are both contagious diseases, and subscribe in all points to the essential features of a contagious disease, they differ very materially in the intensity of their contagion. The organism which produces small-pox finds a congenial soil very readily, runs through the cycle of life very quickly, and exhausts the soil upon which it feeds in a very brief period of time. The organism which produces tuberculosis is implanted with considerable difficulty, runs through its cycle of life more slowly and exhausts the soil upon which it feeds most tardily. The organism which produces small-pox escapes from its host almost immediately after the development of the disease and goes out in profuse numbers from every part of the body, whilst the organism which produces tuberculosis does not escape from its host until the disease has been in progress for a long time, and escapes by a single avenue. In small-pox the deciduous organism is at once set free in the atmosphere surrounding the host, polluting it, and making it intensely infectious, whilst in tuberculosis the deciduous organism is protected by broken-down tissue, with which it has to be carried into the new host, and, therefore, cannot pollute the atmosphere around the host to a very intense degree. The difference in the intensity of contagion between small-pox and tuberculosis is, therefore, very great, and the phenomena by which contagion manifests itself are very different. The essential features of a contagious disease, however, exist in both, and are identically the same. In both we have a living organism, the parasitic existence of which produces the disease; in both we have communicability of that organism; in both contact, direct or indirect, is essential to communicability; and in both the environment under which communicability is operative is limited.

What is true of small-pox and tuberculosis in regard to the individuality of contagion is true of all communicable diseases. Certain groups resemble each other closely, but even in such groups individual members have marked peculiarities. The exanthemata resemble each other closely, all being intense in their contagion and running rapid courses. Leprosy resembles tuberculosis; there is a similarity between the acute diseases of the upper air-passages; and there is a very close resemblance in the mode of distribution of some of the infectious diseases. As a rule, the intensity of contagion or infection is in proportion to the profuseness with which the organism is given off from a host, and the degree to which the deciduous organism is encumbered in its ingress into a new host. Where the deciduous organism is given off through a single channel and is embodied in

broken-down tissue or newly developed tissue, contagion is apt to be mild and erratic.

For preventive purposes a correct classification of communicable diseases, and a careful study of the idiosyncrasies of each disease are of great importance. With contagious diseases the most important factors to be considered are the host and the prospective host; whilst in infectious diseases the most important factor is the intermediate agency of communication. In contagious diseases we should seek to make the host sterile, and the prospective host immune; in infectious diseases we should seek to make the intermediate agency sterile. For example, in small-pox and tuberculosis we have to do first with the person suffering from the diseases; and second, with the persons who may be exposed to the disease; whilst with cholera and typhoid fever we can accomplish most by looking after the water and food-supply or after the drainage of our habitations. With all contagious diseases the prospective host is as important a factor from a preventive point of view as the host himself. With small-pox, immunity can be established by vaccination, and there is promise in the laboratory work of the future that similar results may be obtained with all the intensely contagious diseases. With tuberculosis and some of the more mildly contagious diseases partial immunity can be established by a maintenance of a healthy nutrition. Could all the hosts of contagious diseases be made sterile, or isolated so effectively as to make contact impossible, no new set of hosts could come into existence. In practical life such a condition of things is impossible of attainment; and it therefore becomes most important to work at the other end of the line and reduce the number of available hosts to a minimum. With infectious diseases isolation is futile, except in so far as it will aid in preventing the infection of the intermediate agency of distribution. If every typhoid-fever patient could be isolated, and his discharges sterilised, a time would come when all water-supplies would likewise become sterile, and the germs producing the disease would no longer be distributed. Better results can, however, be attained by at once sterilising all water-supplies.

In order to be able to fully understand the subject of contagion, one must first learn to realize that it is a complex one. With a single idea based upon what can be observed in small-pox and other intensely contagious diseases, one is bound to become stranded in studying the subject. It is a great and an important subject, and we are as yet merely at its threshold. To gain access to all the secrets which it will reveal to us will require long and tedious study in the laboratory, and careful conscientious observations at the bedside, with a mind unfettered by traditions and receptive to new ideas. What we know gives us a good hypothetical basis; what we have yet to learn will give us mathematical accuracy.

A MIRROR OF PRACTICE.

AN OBSCURE CASE OF POISONING.

By G. E. OLAXTON, L.R.C.P. & S., EDIN.,

Medical Officer, Plague Camp, Bandikui.

On the 18th, by the 80 down, a party of well-to-do cloth merchants, consisting of four women, three men, and two children, travelling from Mauli to Hyderabad, Sind, and holding tickets from Ajmere to Muttra, were admitted to this camp, as one of the party, BHOJA, son of THAU, *etat* 30, a well-developed man, had a temperature over 101°, a rapid pulse, and was quite unconscious. He had no enlarged glands, and his heart and lungs were normal. A jalap and calomel purge was administered on admission, which operated; a diaphoretic mixture ordered, and a sleeping draft given at bedtime. His urine was suppressed, but the application of hot dry flannels over the region of the bladder, and placing his feet in hot water, had the desired effect.

On the 19th the patient was better in every respect, his temperature kept below 100°, his pulse rate was reduced in frequency, he could speak, and took the milk diets ordered him. He complained of dryness about his throat, his tongue was dry, though his skin was moist, and he had a slight difficulty with his expectoration. An embrocation consisting of turpentine and chalmogra oils was rubbed on his chest, and treacle and vinegar relieved his expectoration: the juice of oranges abated his thirst somewhat. Towards evening his temperature rose, and as he was restless, 15 grains of pot. brom. and 10 grs. of sod. salicyl. was given, but this was rejected, and by 12 (midnight) he was quite delirious.

On the 20th, about 2 A. M., I was awaked by his shouts, and when I saw him he was crying out for water! water!! water!!! I learnt he had already drunk an immense quantity, but this seemed to aggravate instead of abate his thirst, and he was very anxious his feet and head should be both kept cool. As he proved so troublesome to all around, he had to be tied to the bed. It was impossible to administer medicines by the mouth, for he would shut his lips, clench his teeth, and neither persuasion nor threats would induce him to take these. As talking only excited him, and the presence of any one near by induced this, he was ordered to be kept quiet, and I forbade anyone to pay any heed to his ramblings. At first I thought his mind had become affected, and that he was a fit inmate for an asylum; but later on in the day suspicions were entertained that this was most likely an obscure case of poisoning, and on making careful enquiries from the party with him, I learnt he had been treated in Ajmere by some Vaid. Many of the symptoms—the delirium, thirst, dryness, and suppression of urine—would lead one to suspect some preparation of the natural order solanaceæ had been given in excess. His pupils were normal, would react to light, and when a lantern was brought near him, he was attracted by the light in much the same manner as a person suffering from mental unsoundness. His talk was extravagant, and he harped on the subject of money. To secure the soporific and

antispasmodic action of drugs, onion juice and asafœtida mixed with sweet-oil was rubbed over his abdomen, in the hope these would become absorbed (endemic method). Opium was placed in a chilum, but this had to be done secretly, for he had an idea that churru was being thus administered, and it was not till he had been fully assured this drug was not used that he attempted to smoke the tobacco. By 4 P.M. he was very much better, his talk was more rational, he was not so easily excited, and an hour later he passed his urine, and this the patient informed me was high coloured and scanty. By 6 P.M. he was inclined for food. Milk and jellabies were ordered, and with them was mixed 10 grains of pulv. ipecac. co. The patient had a fair night's rest, he did not disturb those round him, but slept by fits and starts. On this day he dreaded seeing a bottle of any kind, and would wish to carefully inspect the water before he drank it. The endemic application was continued steadily at intervals.

On 21st patient was much better; he still complained of great thirst (this and want of sleep, he it observed, have been the most prominent symptoms throughout); he complained of great internal heat as though the intestines were being burnt, and declared he would die if not relieved; his body was cool to the touch, his tongue not so dry as yesterday, and medicines which he rejected for his relief then he was now as eager to obtain. He is much quieter, but gets excited if he converses for long. Twice a saline purgative (mag. sulph. 3iv.), combined with 10 grains of pot. nit., was administered without effect, and the following mixture:—

R Pot. nit.	grs. 60
Spt. ether nit.	3ii.
Liq. am. acit.	3ss.
Tr aconiti	mxx.
Aquæ	ad	3vi.

Misce. Half ounce to be given hourly, was commenced in the evening for its diuretic and sudorific effects. An acid tonic was ordered in the morning, and a sleeping draft (pot. brom. grs. xx., antifibrin grs. vi.) was ordered at bedtime; a tablespoonful of lucca oil was also administered in the evening. To-day patient is anxious to partake of food, and feels he has an appetite for it. Rice conge, lowki, and mung dal, which are said to have cooling effects, were given.

22nd.—Patient did not sleep well in spite of the draft, but when I saw him in the morning at 8, his temperature was subnormal (97°), he was walking up and down in front of his hut, his bowels had been thrice acted on, his urine was more abundant and not so high coloured, and he was anxious for food. He has kept well during the day, had a bath, his body is cool, his tongue moist, his thirst not so intense, and the internal burning feeling less marked; he has, however, a heavy look about his eyes, and reminds one of a person who has not slept for days. 30 grains of pot. brom. were administered at 3 P.M., and about 10 P.M. 10 grains of pulv. ipecac. co. The tonic and diuretic mixtures were given alternately, the oil thrice daily, and the diet of yesterday adhered to.

23rd.—Patient slept soundly for six hours during the day; he is not talkative, has no thirst, and is placed on his usual diet.

25th.—Patient discharged.

Remarks.—The occurrence of modified symptoms of a deliriant coming on so long after his admission here, his extravagant, excited talk, and being attracted by the light, would throw one off the scent as to what really was the matter and render his case most obscure. If a drug had really been administered in Ajmere, it seems strange such a long interval should have elapsed (midnight of 19th) before he became excited, though he complained of thirst and suppression of urine during the day, and on the 18th—if it had been a drug its effects, which were slow in declaring themselves, very gradually wore off. The native idea was some metallic preparation had been given by the Vaid; this had not been sufficiently burnt, and, to crown matters, the patient did not consume plenty of ghee after it: hence his suffering in the way he did.

PUERPERAL ECLAMPSIA: RECOVERY ON EXPULSION OF ROUND WORMS.

BY ATUL CHUNDBA MOOKERJEE, C.M.S.

Medical Officer, Rai Doorga Prasad Ghose Bahadoor's Dispensary, Solaghur, Dacca.

On the 15th October I was called in to a confinement case, primipara, aged 16, in pains for three days, and suffering from severe spasms.

Condition.—Severe convulsive movements: pulse small and quick: eyes congested: face pale: tongue protruded and bitten: breathing stertorous: patient insensible: examination per vaginam showed rigid os: no foetal heart sound: bowels moved well once.

Treatment and Progress.—Chloral and bromide: at the end of three hours os sufficiently dilated to admit one finger: presentation occipito catyloid: as patient was much exhausted and cyanosed, it was decided to terminate labour: application of cocaine to cervix induced dilatation to size of rupee: chloroform administered: vulva and vagina thoroughly disinfected: bag ruptured and child removed by craniotomy: uterus washed out with Condy's fluid and binder applied: extract ergot liquid 3i given at once. The convulsions, however, returned, and necessitated the re-administration of chloral and bromide, to which was added 5 minims of tincture of musk to each dose. At the same time cold lotion was applied to the shaved head, and the diet consisted of milk and sago. Next day patient was much the same: temperature 102°: pulse weak: quite insensible: had had several severe protracted convulsive attacks during the night: bowels constipated: urine scanty and high coloured: no albumen: no enlargement of liver and spleen: heart and lungs healthy: no polypus in nostrils or ears: tongue coated, protruded and violently bitten: reddish foetid discharge from vagina: no history of venereal disease.

Considering intestinal worms might be the cause, the following was given:—Santonin grs. 5: sodæ bicarb grs. 10: pulv. scammonea co. grs. 10: pulv. jalap co. grs. 10 at bedtime, and mixture of liquor ammon. acetatis: pot. bromid: spt. chloroform: tinct. belladon: and aquæ camphor administered every four hours. At the same time the uterus was washed out with Condy's fluid, and a cork placed between the jaws to prevent the tongue being further injured.

17th October.—Had three motions, with which eight round worms, varying from 8 to 12 inches in length, were passed, and the convulsions ceased almost simultaneously: temperature 99°: pulse better: urine passed thrice with less high colour: regained slight sensibility, and complained of pains all over the body. A mixture of quinine, hydrobromic acid, spts. of chloroform and infusion of quassia was then given every four hours with a diet of milk, sago and soup. After this the patient recovered rapidly under a tonic.

Remarks.—It is perhaps quite probable that the irritation due to the presence of the round worms was the continuing, if not the inciting, cause of the eclampsia, which, as is seen, practically vanished with their expulsion.

A CASE OF OVARIAN CYST, CLOSELY RESEMBLING ASCITES: OPERATION: RECOVERY.

BY LIEUT.-COL. C. M. THOMPSON, M.B., B.CH., I. M. S.,

Staff Surgeon, Civil Hospital, Secunderabad.

(Reported by Hospital Assistant R. YELIAH RAJIAH).

SWAMMAH, a Hindu female, aged 19 years, married, no issues, was admitted into hospital for what appeared to be ascites.

Condition.—Weak, lean, anæmic: distension of abdomen uniform: percussion thrill, general all over: but for absence of albumin in urine and the healthy state of the liver and heart, the case was in all respects similar to one of ascites. A closer examination, however, revealed that the swelling was not peritoneal dropsy.

History.—Not clear: first noticed swelling at lower part of abdomen about 10 or 12 months previously: did not remember whether this was one-sided or general: menses almost regular, but scanty since swelling commenced.

Examination.—Front part of abdomen dull: flanks indistinctly resonant: clear resonance between margin of liver and the upper border of the dulness when percussed with a pillow under the back: swelling soft, very uniform and yielding: per vagina, uterus displaced downwards and Douglas' pouch empty: an obscure bulging on the upper part of the anterior lip of cervix.

Diagnosis.—Ovarian cyst.

Operation.—The usual aseptic precautions with instruments, sponges and towels aid the patient's abdomen: anæsthetised: abdomen opened three inches below umbilicus by median incision: on division of peritoneum, tumour bulged: slight adhesions cleared: SPENCER WELLS trocar introduced and five pints of brown glutinous fluid removed: cyst found unilocular: sac large and thin: pedicle thick and broad, ligatured in three parts and the stump left in the abdominal cavity, which was irrigated with warm salt solution and sponged. The peritoneum, muscles and skin were stitched together by one silk ligature: after-treatment simple: nothing given for eight hours, after which tablespoonfuls of water were administered occasionally until next day, wheniced milk and water was allowed for two days, when broth was added on the sixth day, after which a little well-boiled rice and milk was given. The progress was uninterrupted, except on the fourth day, when there was a rise of temperature to 100° and some discomfort of the bowels, both which were relieved by a warm turpentine enema. The sutures were removed on the eighth day, when the wound was found to have healed by first intention. The parts were well strapped and the woman allowed to sit on the twentieth day, and discharged on the fortieth day after the operation.

Indian Medical Record.

9th January 1901.

A COMPLETE EXPOSURE OF THE AMERICAN BOGUS M.D. BUSINESS.

ABOUT nine months ago a Bengali, who signed himself as H. L. M. S. (Homœopathic Licentiate of Medicine and Surgery), addressed the Secretary of the Indian Medical Association, desiring admission into the Association as a "qualified medical man." He was informed that he could not be admitted into the Society with a "Certificate" from the Calcutta Homœopathic Medical School. Three months ago this same person again applied for admission to the Association, stating this time, that he had "now obtained the degree of M. B." Upon this the Secretary enquired the source of the "degree," the nature of the examination for it, and the status of the examiners. This elicited the following startling information:—"The degree of M. B. was obtained from the Western University of Chicago, the question papers were sent to a Babu in Calcutta, named BHUBAN MOHAN BANERJEE, M.A., LL.D." (whose degrees are probably of Western University manufacture), "and this gentleman conducted the examination, forwarding the answers to Chicago, and receiving the 'diplomas' for the 'successful' candidates." In this delightfully simple manner a number of uneducated natives, most of whom are the products of that bogus institution called the "Calcutta Homœopathic Medical School," have received bogus degrees, and are probably now plying their "trade" as M.Ds. The Secretary of the Indian Medical Association, on obtaining the above information, sent a copy of the correspondence alluded to, to the Secretary to the State Board of Health of Illinois, the State of which Chicago is the capital, asking for information regarding the Western University of Chicago. The following is the official reply:—

"OFFICE OF THE STATE BOARD OF HEALTH, ILLINOIS;
SPRINGFIELD, the 3rd December 1900.

JAMES R. WALLACE, M.D., F.R.C.S.,

50, Park Street, Calcutta, India.

DEAR SIR,

In reply to your favor of October 25th, 1900, just at hand, I beg to inform you that there is not now, neither has there been at any time, a medical Institution in the city of Chicago, named the Western University of Chicago.

The People's Institution, a building on the corner of Leavitt and Van Buren Streets, sheltered in 1899 not only the Independent Medical College and the "Metropolitan Medical College," both fraudulent institutions, but also the "Western University of Chicago," a corporation organized by one J. H. RANDALL, "Ph. D." "M. D.," etc., etc., who was "Professor" of Biology, Chemistry, Hygiene, Tokology, Dentistry, Etiology and Psychopathy, in the "Independent Medical College." Mr. RANDALL was evidently not satisfied with his share of the proceeds derived from the sale of the "diplomas" of the "Independent Medical College," so he organized a corporation (?) of his own, labelling it the "Western University," and proceeded to run it in competition with the "Independent," and from a college office of about 8 x 10 feet, he commenced the grinding out of a miscellaneous assortment of "degrees" to persons who fancy such articles.

Although apparently conducted as a separate Institution, it is stated that the "Western University" was in har-

mony with the "Metropolitan Medical College," the successor of the defunct "Independent," a college which is now enjoined by the courts from conferring any more degrees. Mr. RANDALL was also a "Professor" of Dental Surgery and Anatomy, Physiology and Chemistry at the "Metropolitan."

I am told that the "degrees" of both Institutions were signed by the same office girl.

Undoubtedly the "examinations" in India and elsewhere were conducted on the plan inaugurated by "Professor" VAN NOPPEN, of "Independent" fame.

I think that you have sufficient information regarding the Western University.

For your further information, I will say that the following named "Institutions" in Chicago, some of which are still in existence, are fraudulent. None was ever a medical college in any sense of the term. They were simply corporations organized for profit, the profit being derived from the sale of diplomas, and by the promoters of such diplomas, were sold to all comers:—

- The National University of Illinois.
- The Chicago College of Science.
- The German Homœopathic Medical College.
- The German Medical College.
- The German American Homœopathic Medical College.
- The Illinois Health University.
- The American Health University.
- The Academia Illinois.
- The Illinois Standard College of Medicine and Surgery.
- The Dutton Medical College.
- The Chicago Seminary of Sciences.
- The Independent Medical College.
- The Western University.
- The Metropolitan Medical College.
- The International University.

There are some others, but the above comprise those most prominent in the industry.

I am surprised that the gentleman, the correspondence with whom you enclose, should content himself with a mere M. B. degree, when, for the expenditure of a little more of the coin of the realm, he could have, in addition, the titles of LL.D. and Ph. D. conferred upon him.

Yours very truly,
J. A. EGAN, M.D., Secretary."

The Government and the public have now a list of no less than fifteen of the principal American "Institutions" in Chicago which have carried on, and are still carrying on, a disgraceful and nefarious traffic in the sale of medical diplomas. Their plan of campaign is demonstrated in the instance of the "Western University of Chicago," which does "business" in Calcutta through the agency of Babu BHUBAN MOHAN BANERJEE, M.A. LL.D., whoever this individual may be. Here we find a Bengali (the applicant for admission to the Indian Medical Association), who is very imperfectly educated in English, going through a few "lectures," with no hospital training, no experience, and no real technical education in Medicine, launched out with a "diploma" which is a spurious and colorable imitation of the Calcutta University L. M. S. degree, by a bogus "School" of Homœopathy in Calcutta, a man utterly unfit to treat the sick for medical ailments, and admittedly unqualified to give relief in a surgical case—for homœopathic schools do not, and cannot, teach surgery—given the diploma of H. L. M. S. (Homœopathic Licentiate of Medicine and Surgery), and this is the kind of person to whom the "Western University" grants the honorable title of M. B. No exposé could be more thorough in its utter and complete condemnation of a fraud, than this single instance of American rascality. But it is only one of many of the same type, as the police will soon discover.

Utterly disgraceful as it is to find irresponsible American harpers selling medical degrees in India to gullible quacks, with only a smattering of homeopathic ideas of treatment, how grossly reprehensible must it be for the Government of Bengal to allow bogus Institutions like the Calcutta Homeopathic School, and two other Bengali schools in this city, to be drafting out on the public, year after year, shoals of ill-trained and positively illiterate "practitioners," armed with diplomas from the "authorities" of these bogus Calcutta schools. Of course let us have independent schools, but let them be properly equipped, properly officered, and let their examinations be placed under Governmental inspection. If there is to be a regulated system of medical practice in India, the sooner the task of State control and registration are taken in hand, the better will it be, not only for the public, but for the Government, as in a few years the country will be literally overrun with the rag-tag and bobtail of a rabble from the bogus "schools" of Calcutta, all styling themselves "Physicians and Surgeons" and "duly qualified" medical men.

With this complete list of the Chicago Diploma Mills in their hands, the Government and the Police authorities ought to find it easy to arrest the "agents" of these fraudulent Institutions, by demanding from every "suspicious" practitioner, making use of the honorable titles of M.B. and M.D., the source of issue of his "degree." Let us hope that another serious blow has now been effectively dealt to fraudulent sellers and fraudulent buyers of American degrees in Medicine, and that the public will soon see the end of this traffic.

MODERN IDEAS ABOUT TETANUS.

At a recent meeting of the New York County Medical Society, the important subject of tetanus was taken up for discussion. We give a summary of the proceedings, details of which appear in an American contemporary. Dr. ALEXIS V. MOSCHOWITZ, in opening the discussion, observed that such phrases as traumatic and idiopathic tetanus were no longer recognised. The tetanus bacillus entered through a breach of continuity and multiplied at the point of infection. It did not find its way by metastases through the system. During its growth toxins of an intensely virulent character were produced, and their absorption caused the symptoms of tetanus. The division of tetanus into cephalic, puerperal, tetanus neonatorum, etc., was justified by the train of symptoms in each variety. Trismus was usually the preliminary sign. The pathology remained as yet indefinite. The most uniform pathological condition noted was a hyperæmia of the nerve centres. The normal brain and cord substance had been found to be capable of neutralising, to some extent, tetanus toxins, and it was in the cerebro-spinal fluid that the most virulent toxin of the disease was found. These toxins, formed at the point of inoculation, seemed to find their way into the central nervous system through the perineurium of the nerves, and its main point of attack in the spinal cord was the large cells of the anterior horns. The prognosis depended upon the length of incubation, and upon the acuity of the affection. The mortality had been placed, prior to the use of antitoxin, as high as 96 per cent. Of 290 cases treated with antitoxin subcutaneously, 117 had died. The percentage of recoveries in 48 cases treated with intracerebral injections had been a little over 50. The indications for treatment were: (1) Destroy the bacteria present, and prevent the further absorption of toxins—the wound of entrance should be enlarged, dust and foreign bodies removed, and a thorough disinfection of the tissues insisted on. (2) Eliminate, as far as possible, all toxins that had been absorbed—catharsis and diuresis, and possibly venesection, as much normal salt solution being introduced beneath the skin as there was blood removed. (3) Failing to eliminate, neutralise the

toxins already in the circulation, and further anticipate the symptoms of the disease and its development by immunising patients before the disease developed antitoxic treatment. Unfortunately, however, before symptoms of tetanus announced themselves, the toxins of the disease had become more or less permanently fixed in the cells of the central nervous system, where the antitoxin was unable to affect it. Immunity could be produced if the antitoxin was given before symptoms of tetanus declared themselves. When symptoms had developed, it was not the beginning of the tetanus, but the beginning of death from tetanus. The most promising field therefore for antitoxin subcutaneously was its use as a prophylactic. The subcutaneous injection of antitoxin had, however, undoubtedly lessened the death-rate from this disease. The intracerebral injection of antitoxin was of service, although a definite idea of its value could not perhaps as yet be given. (4) Overcome the symptoms of the disease by the administration of remedies that promised to have an opposite effect upon the organism—chloral, bromides, opium and hyoscyanus. Subcutaneous injections of brain substance, and the injection of large amounts of carbolic acid, seemed not unworthy of consideration and trial. Dr. WILLIAM H. PARK, who followed this speaker, said that the surgical treatment of wounds inflicted on the street should be most carefully attended to. If the wounds were opened at the beginning, the tetanus bacillus would not grow. If even after the development of the first symptoms we knew where the wound of entrance was, it should be opened up to remove the bacilli and prevent the absorption of further toxins. Although the prophylactic employment of antitoxin was valuable, once the symptoms of tetanus had manifested themselves, the use of antitoxin did not seem to influence the course of the disease, for the cells of the central nervous system were then ready to die. The use of the serum by intracerebral injection did not seem to add to its value. Dr. ROBERT ABBE detailed his personal experience with antitoxic serum (intracerebral injection) in the treatment of tetanus. On the whole, he found its use of decided benefit, and he believed firmly that it had a great future. The appearance of the wounds through which infection took place was very varied, and in no way coincided with the severity of the attack. As in cases of anthrax, there was at times an oedematous, hard, pork-like condition of the surrounding tissues. Some of the cases that began mildly had severe exacerbations, and it was not an unusual thing to have a sudden relapse more severe than the rest of the disease, after a seeming recovery. Dr. CONVERSE reported an interesting case of infection through frost-bite, in which, after an apparent cure by amputation and the subcutaneous injection of antitoxin, death ensued from pyæmia. The pyæmia seemed to be due to infected serum, the vial which contained it having been allowed by mistake to stand unwrapped and uncorked for some time. Dr. M. WARE said that the tetanus bacillus absolutely refused to grow in the presence of oxygen. It found favourable conditions only in the depths of the tissues, where free oxygen was excluded. The cardinal prophylactic indication, therefore, was to lay open all wounds made on the street, so thoroughly that they might have free access of air. Cauterisation was inadvisable, as by matting the tissues together it shut off the air, and thus created favourable conditions for the multiplication and growth of the bacillus. Dr. FISHER thought there was no reason to consider that the nerve cells were affected by the tetanus toxin. When cells of the central nervous system were affected, the usual result was a palsy; convulsions were never produced. It was probable, therefore, that the pathological lesions of tetanus would not be found in the cells, but rather in the meninges. In closing the discussion, Dr. MOSCHOWITZ remarked that with proper aseptic precautions, intracerebral injections were undoubtedly of the greatest service, and a distinct advance in the therapeutics of tetanus.

COMMENTS AND NEWS.

THE I.M.S. AND THE EDITOR OF THE "INDIAN MEDICAL RECORD."

Some I.M.S. men in Calcutta have stated that the reason that the *Indian Medical Record* is "so dead against the I.M.S.," is that the Editor (Dr. J. R. WALLACE) appeared in the London competitive examination for the I.M.S. and failed to get in, and that he therefore shows the strongest antipathy to the I.M.S. in consequence. It becomes our duty to deny the story. Dr. WALLACE appeared for the examination of the Royal College of Surgeons and Physicians of Edinburgh in February 1880. He topped the list of 64 candidates from the English, Irish and Scotch schools, and was complimented by the Presidents for the excellence of his papers and for his work at the practical part of the examination. Among the 64 candidates was one of the present "I.M.S." Professors of the Calcutta Medical College. Dr. PATRICK HERON WATSON, Vice-President of the R. O. S., Edinburgh, to whom Dr. WALLACE had been most favorably recommended by Dr. DAVID B. SMYTH, then Principal of the Calcutta Medical College, wrote to Sir JOSEPH FAYRER, the medical adviser to the India Office, telling him of Dr. WALLACE's great success in Edinburgh, and asking that his special attainments might receive the recognition of the India Office. Sir JOSEPH FAYRER thereupon advised Dr. WALLACE not to appear in the London competitive examination for the I.M.S., as he (Sir JOSEPH FAYRER) stated that the India Office would give Dr. WALLACE a special appointment in India, with good prospects, such as would not be immediately open to him if he entered the I.M.S. He could easily have come near the top of the list of that term for the I.M.S. with the class of men who got in then, and even with a stronger lot. Dr. WALLACE, however, took Sir JOSEPH FAYRER's advice, and did not appear for the I.M.S. competitive at that time, nor at any other time. He was immediately on his return to Calcutta appointed Resident Surgeon to the Medical College Hospital as a direct result of Sir JOSEPH FAYRER's kindly influence. We trust that the gentleman guilty of the misstatement herein referred to will now find sufficient cause not only not to repeat a story which is absolutely without foundation, but to contradict it, as the obvious double intention of the fabrication is to imbue the public with a belief that our comments on, and criticisms of, the I.M.S., are biased and tainted with malice arising from offended pride, and that the Editor of the *Record* was so sadly lacking in professional qualification as to fail in the ordeal of entering the I.M.S. by open competition!

NEW TREATMENT FOR DIABETES.

WE take the following from an article contributed by Dr. WILLIAM RUSSELL, M.D., F.R.C.P., to the *Medical Brief*, on A New Treatment for Diabetes. Without referring to the familiar features of the symptoms, etiology and pathology of diabetes mellitus dealt with by the writer, we proceed at once to give a summary of that portion of the paper relating to the treatment of a case with fresh thyroid. The patient, a married woman, was admitted to hospital on the 16th August: no family history of diabetes, phthisis, or insanity, nor of accident or injury; husband perfectly healthy (doing away with any probability of microbial origin); history of sudden shock with symptoms of thirst and excessive micturition a fortnight later; weakness progressed until on admission her weight was 93 pounds. She was passing a little over 100 ounces of urine in 24 hours: acid; specific gravity 1046: no albumin; large quantity of sugar; organs apparently healthy. Reviewing the probable causes of the ailment, it was decided that a nervous disturbance had given rise to a vaso-

motor paralysis, and thus to a more rapid blood-supply to the liver and other organs. During the first fortnight the patient was kept in bed on ordinary diet and no medicine, and an average of 14 days' observation showed that the patient passed in 24 hours 112 ounces of urine containing 5848 grains of sugar. The writer had little faith in the usual remedies—opium, morphine and codeine—and even nitrate of uranium. It seemed to him that what was wanted was a drug which would get rid of the sugar from the urine without the necessity for restricting the supply of carbohydrates, and that this remedy would be found from a study of organo-therapy. Feeding with pancreas had proved unsatisfactory with others, so thyroid feeding was adopted, and preference given to fresh thyroid, every precaution being taken to procure reliable glands. This was made into pills, each pill containing 4 grains. Three pills were given three times a day,—36 grains in 24 hours. After the third dose headache and giddiness was complained of, and the treatment suspended. Five days later the treatment was resumed, two grains being given every three hours. This time no inconvenience was experienced, but two days after the temperature rose to 100·6, pulse to 104, with pain in chest and watery eyes, and a rash over the upper part of the thorax, over both scapulae and on the anterior and external aspects of both thighs of a bright red color, almost papular. It might have been a thyroid rash, or it might have been a toxic erythema due to meat poisoning. On the next day treatment was resumed, first with 6-grain, and then in 12-grain doses every three hours, and kept up for almost a month. Tolerance was established. Diet during this period consisted of meat, bread, butter, tea, potatoes and milk gruel, and was practically unrestricted. Sugar sank to 8057 grains after 14 days, and in the last three days to 1180 grains, thus showing a fall of 4668 grains. The thyroid treatment was then suspended and the patient dieted. After eight days 3440 grains of sugar was found in 24 hours, being 2260 grains more than on an unrestricted diet, plus thyroid feeding. The quantity of urine passed was also proportionately affected, and so was the body weight. The patient became an out-patient and returned from time to time. The effect of thyroid feeding was, said the writer, undoubtedly transitory, and the administration of the drug must be maintained. The thyroid yielded an internal secretion which effected some useful purpose in the animal economy. Probably it possessed the power of destroying the toxic products of metabolism. One of its most noteworthy effects was the increase it produced in the oxidation of the tissues of the body. If PAVY's theory that glycogen was converted into fat was accepted, we had a clue to the action of thyroid in the treatment of diabetes. The writer thought that the treatment would be found most efficacious in those cases, of glycosuria occurring in elderly people in which obesity was a prominent feature.

NEW ARMY DOCTORS.

WE quote from the *Statesman*:—The report of the Royal Commission on the Treatment of the Wounded in South Africa will deal at length with the organisation of the Army Medical Corps and the difficulties with which it has had to contend. Owing to the peculiar circumstances of the case, it has been practically impossible to induce young doctors to enter the competition for the Army, and excessively difficult to obtain them by nomination. Of late years the emoluments of the staffs of the great civil hospitals have materially increased, and this is an obvious reason why, in order to secure competent men, the War Office must hold out greater inducements than are at present offered to doctors desirous of joining the service.

There is another important consideration, apart from the financial question to which the Commission has given its attention. It is now recognised as essential that army doctors must have adequate leisure for study and for recreation. Year by year more rapid strides are being made in medical science, and particularly in surgery. After a doctor has served five years abroad, he finds on returning to England that he is behind the times. In order that he may acquaint himself with the discoveries made in the interval, he should have a certain period given him to bring his knowledge up to date. But in consequence of the small number of medical officers available, it has been impossible for the authorities to grant the requisite leave, and this naturally has not tended to increase the efficiency of the corps.

There is no question of reverting to the old system under which each regiment had its own medical officer. This, it has been pertinently pointed out, would be putting back the hands of the clock. The tendency in Continental armies to-day is to follow in the direction which has been pursued here. On this head it is recognised that no doctor would care, for instance, to be appointed to a crack cavalry regiment where a large private income would be essential. Here is a point affecting the individual doctor, but there are various other objections which concern the whole problem of medical organisation. The Royal Commission has cost many thousands of pounds, and it is anticipated by those who know the shortcomings of the existing system that some material good will result from its labours.

INDIAN AND COLONIAL ADDENDUM OF 1900 TO THE BRITISH PHARMACOPEIA OF 1898.

This addition of 59 special pages to the British Pharmacopœia, makes official, a long list of well-known indigenous drugs and preparations of great therapeutic value and well-established reputation in Indian pharmacology. We refrain from entering on those drugs that do not commonly belong to India, but every experienced practitioner will frankly admit that the scientific recognition of certain Indian remedial agents, such as we append, and their inclusion into the "Imperial" Pharmacopœia, exhibits not only sound sense on the part of the British Committee, but it also places within the reach of practitioners in Great Britain and the Colonies a class of drugs that deserve a high place in the armamentarium of every unprejudiced healer of disease. We mention a few excellent Indian drugs which find place in the Addendum :—

Acalypha, *mylabris*, *urgingea*, *adhatoda*, *andrographis*, *aristolochia*, *azadirach* (neem), *berberis*, *betel*, *butea*, *caloptis* (mudar), *gamboge*, *black catechu*, *cissampelos*, *datura*, *gossypium*, *hygrophila*, *ispaghula*, *sappan*, *toddalia*, *kuladana*, *tinospora*, *ajowan*, *arachis*, *gynocardia*, *lemon-grass*, *sesame*, and many others.

We cannot withhold the remark that the Hindustani names of these drugs should have been introduced, for this would not only have made the collection of such indigenous products easy for pharmaceutical collectors, but it would have rendered this section of the British Pharmacopœia far more interesting and useful to thousands of Indian practitioners. As things now stand, such men must search old books for guidance, and old books are not to be had, save in large libraries.

THE CHIEF JUSTICE AND THE DOCTOR'S CERTIFICATE.

SIR W. BONSER, the Chief Justice of Ceylon, has issued a rule on Captain J. B. REDDICK, R. A. M. C., to show cause why he should not be committed to prison or otherwise punished for contempt of Court. It appears that Dr. REDDICK gave a certificate to Major PAIN, who had been summoned to serve on the Jury, certifying that the Major was not well enough to serve. The Chief Justice took

exception to the terms of the certificate and refused to accept it, remarking that it was the duty of the doctor to state what the illness was the Major was suffering from, and the duty of the Court to decide whether the statements in the certificate were sufficient to entitle the holder thereof to exemption. The certificate was accordingly rejected. On Dr. REDDICK hearing of this, he addressed a letter to the Chief Justice, expressing his surprise at his course, demanding an apology, and threatening, in the event of a sufficient apology not being forthcoming, to represent the Chief Justice's conduct to the Imperial authorities. On receipt of this letter His Lordship ordered the rule *nisi* to issue.

Dr. REDDICK finding he had offended the dignity of the High Court, offered an apology, which the Chief Justice accepted, remarking that Captain REDDICK, while shielding his professional reputation, should have displayed more prudence and discretion.

"L. S. A., LONDON, PHYSICIAN AND SURGEON."

The Hospital says :—The title and description by which the London L. S. A. is in future to be known as "Physician and Surgeon." As we lately stated, the Society of Apothecaries undertook some time ago to protect any of its licentiates from the consequences of assuming the title of "Physician and Surgeon," and they have now resolved that this is the only title which the Society can authorise as a proper description of those holding the qualification L. S. A., 1886. This may either be added to the title of L. S. A. or used alone. The Society has also decided to discourage, in every possible way, the use of any other title by their licentiates. This is as it should be. The L. S. A. is a good, old and respectable qualification, and in view of the fact that while the old title of Apothecary has practically lapsed and become meaningless, the L. S. A. is now a fully qualified practitioner of both medicine and surgery, it seems but right that he should be given a title which shall express his position; but the claim to all sorts of fancy letters after his name, which has been put forward by some writer, is absurd, and should be at once put down.

NEW YEAR'S MEDICAL HONOURS.

The Gazette of the 1st January 1901 contains the following honors to medical men :—

C. I. E.

Major JOHN CRIMMIN, V.C., I. M. S. Health Officer, Bombay.

THE KAISER-I-HIND GOLD MEDAL

Dr. A. NEVE, Kashmir.

THE KAISER-I-HIND, SILVER MEDAL.

Lieutenant-Colonel MATHEW LORENZ BARTHOLOMEUSZ, M.B., O.M., I. M. S., Bombay Presidency.

Miss ALICE CORTHORN, M.D., B.Sc., Poona, Bombay Presidency.

Major WILLIAM HENRY BANNER ROBINSON, I. M. S., Civil Surgeon of Bikanir, Rajputana.

Rao Sahib.—Senior Hospital Assistant LUXUMON GOPJI MATKAR, I. S. M. D., Bombay.

INDIAN MEDICAL SERVICE DINNER.

The members of the Indian Medical Service in Calcutta and its neighbourhood held their annual dinner on the 2nd January at the Saturday Club. Surgeon-General HARVEY presided, and covers were laid for 60 persons. Everything was of the very best, and PELITI personally superintended the arrangements. The table decorations were particularly fine. The usual after-dinner toasts were proposed and duly honoured. Dr. HARVEY's speech was in brief an injunction to his hearers to "Love the Government of India," "Trust the Director-General." Imagine such a thing! Fancy real I.M.S. "Professors" being so lectured. This looks much like *ataxia* somewhere.

REFORMS IN THE ARMY MEDICAL SERVICE.

The Medical Brief says:—A Sub-Committee of the Parliamentary Bills Committee of the British Medical Association is about to invite the medical schools and colleges to state the reasons why well-qualified candidates do not join the R. A. M. C. We suspect the main reasons will be found to be insufficient pay, long foreign service, and want of study leave. Meanwhile we note with satisfaction that in the latest edition of the Regulations for the Army Medical Service the Surgeon-General of an army in the field is restored to his proper place on the staff of the General Officer Commanding-in-Chief. He was removed from that position against the protests of those who take an enlightened interest in the health and well-being of the army. The experiences of the war in South Africa have hastened his restoration to a position from which he should never have been removed. What is still wanted is that his staff of a secretary and orderly officers should also be restored. We also notice that steps in local rank in South Africa have at length been conceded to officers acting in administrative positions superior to their army rank. Two most important administrative reforms on which we have insisted have thus been accomplished. They are probably the prelude to others of a far-reaching kind, for Mr BRODRICK, in his speech, is reported to have said that the War Office was only waiting for the report of the Hospitals Commission in order to take prompt action on army medical matters; and "no preconceived ideas would prevent the taking of measures, however drastic, necessary to put the service on a 'proper footing.'"

RETURN OF A DISGRACED "AMBULANCE" CORPS.

The New York Medical Record says:—Thirty-three members of the Chicago Irish-American Ambulance Corps, which left this city to help the Boers in the Transvaal last February, got back on the steamship *Trave*. There were fifty-eight men in the corps, among them six physicians. They were Drs. J. R. MACNAMARA, HERBERT MCAULEY, JAMES J. SLATTERY, R. L. LONG, A. F. CORNEY, and J. B. ADERHOLT, all of Chicago. GEORGE CASSIDY went as a nurse. The other fifty-one were supposed to be litter men. Before leaving this country each of the fifty-eight men went before a Justice of the Peace and made affidavit that he was going to South Africa, not as an ally of the Boers, but as an ambulance man, and each man pledged himself not to fight. Miss CLARA BARTON gave the Irish-American Corps a Red Cross flag and recognised the organization as a Red Cross auxiliary. The six physicians and the nurse adhered to their pledges, but all the others entered the fighting ranks of the Boers the minute they reached the Transvaal. Some of the men were killed, some were captured or ran away, and some are still fighting. We are pleased to note that the reception the returning band of pledge breakers got from the committee which had been appointed to meet them was far from cordial, and instead of congratulations, they received reproaches for having perjured themselves.

IMPUDENCE OR IGNORANCE.

Indian Engineering says:—The Chief Medical Officer of the Eastern Bengal State Railway has evidently a great conceit of himself, and it illustrates, of course, the usual result of the absurd experiment of putting a beggar on horseback. Despite of the fact that his tenure of service is exactly on the same conditions as those which control the conduct of a first-class porter, he is indignant that the Inspector-General of Civil Hospitals in Bengal should concern himself in any way with the medical administration

of a State Railway in the Province, and implies that Dr. HENDLEY would have quite enough to do were he to look after his own legitimate work. Verily this local medical magnate is imitating the frog in *Æsop's* fable, and if he does not take care he will burst.

THE DOCTOR'S DUTY CALL.

Our ancient lesson will be ever new;
That priceless lesson will be ever true;
Time did not teach it, time will change it not.
This, this shall last though all our lore's forgot.
To give what none can measure, none can weigh,
Simply to go where duty points the way;
To face unquestioning the fever's breath,
The hundred shadows of the vale of death;
To bear Christ's message through the battle's rage,
The yellow plague, the leper's island cage,
And with our noblest "will to understand
The poor man's call as only God's command."
Ay, under every century's changing sky
Shall the Greek Master's triple signal fly—
Faith, honour, duty—duty calmly done,
That shouts no self-praise o'er a victory won;
One bugle note our only battle call,
One single watchword, Duty! that is all.

DEATH OF AN EMINENT ANGLO-INDIAN SURGEON-GENERAL.

The death is reported at Stuttgart, in Germany, on the 29th ultimo, of Deputy Surgeon-General J. Keess, a Eurasian gentleman who retired from this country in January 1887. He was essentially a self-made man, who rose to the position he occupied entirely by his own exertions. Entering the Indian Medical Service in 1856, he was selected ten years later by the Madras Government for special duty in connexion with the Government Cinchona plantations, his reports on which attracted much favourable notice. In the same year he was appointed a Professor in the Madras Medical College, of which he subsequently rose to be Principal.

SHORT ITEMS AND PERSONALITIES.

An Indian paper says:—It is the day of the Kaviraj in Calcutta. One advertises that his medicines, rare and valuable, are "prepared under his strictest supervision and from genuine ingredients." The medicines are "super-excellent," while the prices are "just to suit all purses." Whatever the ingredients, whatever the value of supervision, and whatever the cost of preparation, the medicines sell at all prices from zero upwards.

We are glad to hear that Rai Bahadur Chuni Lal Bose, M.B., F.C.S., has made an original research into and discovered a powerful poison from the *Karabi*. The university has awarded the Coates Memorial Medal to the Rai Bahadur. We hear that the Government intend publishing the research in the annual memoirs of original research in Science and Art. We offer to the Rai Bahadur our hearty congratulations.

Sir Henry Thompson, the eminent surgeon, says that at over 80 years of age he has as strong a belief in total abstinence as ever, and strictly practices it; he confirmed this in a subsequent interview, and further mentioned the interesting fact that, having experimented upon himself at 70 years of age, he found that the use of even a very moderate quantity of wine was detrimental to his enjoyment of perfect health.

Gurdaspur was quite *en fêre* on the 20th ultimo on the occasion of the marriage of Miss Louise Le Marchand, second daughter of Mr. W. J. Le Marchand, District Superintendent of Police, and Captain E. Montgomery Williams, Royal Army Medical Corps, son of Colonel Montgomery Williams, late 1st Battalion, Prince of Wales' Leinster Regiment (Royal Canadians).

The troops in Quetta are still suffering abnormally from enteric fever. Major Davies, R.A.M.C., who had been deputed with Major Elliott, R.A.M.C., to investigate the cause of the outbreak, has proceeded to Army Head-quarters in order to place certain deductions before the highest authorities, and on his return to Quetta shortly the inquiry will proceed.

Major Hendley, I. M. S., Officiating Professor of Materia Medica in the Lahore Medical College, has been selected to take medical charge of the young Maharaja of Patiala and also to act as medical adviser to the State. Captain James, who is at present temporarily lent to the State, will probably return to Umballa.

In the annual report of the Cork District Lunatic Asylum the Resident Medical Superintendent says:—"The close affinity of intemperance to insanity in this country is not sufficiently recognised amongst the public; few know that the children of the habitual drunkard are almost certain to become epileptic or insane."

The Ceylon Contempt of Court case has ended happily for all parties. Captain Reddick, R.A.M.C., has apologised to Sir W. Bonser, the Chief Justice, for having written the letter to which his Lordship took exception. His Lordship said that Dr. Reddick was right in shielding his professional reputation, but he should have acted more discreetly.

Lieutenant-Colonel Crofts, who was and still is in medical charge of the S. S. *Gwalior*, is living on board the ship. The *Gwalior* will land her sick men and then go back to China. Colonel Crofts will not, we understand, go in her, but revert to the medical charge of the Gwalior State.

The Secretary of State proposes to make an alteration in the regulations for admission to the Indian Civil Service by abolishing elementary chemistry and elementary physics from the list of subjects. Higher chemistry and higher physics remain.

Advices received here recently notify that the preparation of smokeless powder being in full swing in Kabul, and, what is more important, the chemicals necessary are all produced locally.

We are glad to hear that Colonel G. Ranking, who was unfortunate enough to lose his eye the other day through an accident at cricket, has now quite recovered from the operation.

Surgeon-General C. E. McVittie, I.M.S., lately Surgeon-General with the Madras Government, and Colonel J. H. Newman, I.M.S., lately Principal Medical Officer, Lahore, have been granted good service pensions.

Nursing Sister Miss M. E. Gray, Indian Nursing Service, from Madras, is posted to the Allahabad Station Hospital.

The official estimates for next year place the requirements of the army in India in medical stores at ₹23,000.

Lieutenant-Colonel Boyd, I. M. S. (Bombay), has been selected for appointment on the administrative grade.

Major De Costa, I.M.S., a prominent Goanese, has been permitted to retire from the service.

WANTED—A THIRD GRADE HOSPITAL ASSISTANT to come to Burma on mutual transfer with the undersigned. Any one from Punjab or N.W.P. will be accepted. For particulars, address:—

H. A.,

C/o Manager, "Indian Medical Record."

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE INDIAN MEDICAL RECORD will, upon publication, be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary, to elucidate the text, illustrations will be provided without cost to the authors. Address the Editor, JAMES R. WALLACE, M.D., F.R.C.S., 50, PARK STREET, CALCUTTA.

NOTICE.

All members of the Indian Medical Association are kindly requested to send their names in full with their present addresses, clearly written, to the Secretary.

Members who have paid their subscriptions and who have not received the membership certificates are kindly requested to notify the same to the Secretary.

VITAL STATISTICS OF CALCUTTA.

Statement of Deaths from Principal Diseases in Calcutta from the 1st to the 22nd December 1900.

EXISTING MUNICIPAL LIMITS.

J. N. COOK, D.P.H., Health Officer of Calcutta.

Current Medical Literature.

MEDICINE.

Pathology and Etiology of Rheumatism.

C. R. MARSHALL, in the *New York Medical Journal*, says that the pathology and etiology of rheumatism are still not clear. The existence of lactic acid in the economy is a predisposing cause of the disease, but there is no conclusive evidence that it is the exciting cause. Reduction in the alkalinity of the blood is a prominent feature of the disease; this may follow the suppression of perspiration, the ingestion of food containing a high percentage of acid, or the absorption of products of acid fermentation in the gastrointestinal tract. Nutrition is inhibited by diminished oxidation; reduced alkalinity of the plasma means diminished oxidation and consequently retarded nutrition. Defective oxidation is most generally observed in warm and damp climates; the clear, cold, and dry air of winter acts as a stimulant to those processes, which are then so much accelerated that many of the phenomena characteristic of rheumatism are checked or fail to appear. The prompt and systematic administration of alkaline salicylates is the only safe plan to adopt in the treatment of the acute type of articular rheumatism. Salicylic acid is freely absorbed by the skin and may be applied in the form of an ointment; the physiologic effects of the salicylates are manifest in a short time, but no gastric complications occur. The application is covered with impermeable material.

Treatment of Sleeplessness.

DR. JOHN B. BRADBURY, in his Croonian lectures (*Brit. Med. Jour.*), remarks that the treatment of insomnia often resolves itself in a study of the causes. First, there are the irritative causes, as pain and uneasiness, such as children teething, or the presence of worms. Eye-strain or eczema keeps many an adult awake. Then we have the toxic causes, as alcohol, tobacco, the poisons of febrile diseases, conditions present in gout and rheumatism, and the toxins left in the system through bad circulation, kidney diseases, etc. Further, there are the mutual causes of grief, worry, shock and anxiety. There is usually in these cases a nervous temperament. There are also cases of insomnia due to change of habits and mode of life, such as late dinners, high altitudes, changing from day to night duty, or *vice versa*. No treatment of insomnia can be successful that is not deduced from a study of causes. But even though the causes have been sought out and removed, sleep may not return. The cells of the brain have become irritable. In mild cases, try bromides first. Paraldehyde is one of the best hypnotics. Chloramide is good and safer than chloral. Sulphonal is the best of the sulphones.

Hysterical Skin Affections.

RASCH records a case of factitious, vesicular, bullous, and gangrenous dermatitis, occurring in a young female servant, aged 18, with hysterical stigmata. She was under observation either as an out-patient or in-patient at the Copenhagen Communal Hospital, from October 1896 to October 1898, but it was only in March 1898 that the fraud was exposed by the patient confessing she had herself produced the original bullous eruption by means of cantharides plaster. An interesting point in the patient's family history was the fact that her father's brother and her mother's sister had suffered from mental disease. There was no sign of congenital syphilis, though the mother's history of eight confinements, two children only surviving, and abortions, pointed that way. Some of the old lesions presented keloidal scarring. The author points out that the factitious nature of these eruptions are but too frequently erroneously attributed to a purely vasomotor and tropho-neurotic origin. He gives some instances of published cases which were subsequently shown to have been self-induced. RASCH also refers to the view of the Salpêtrière School that gangrenous ulceration of the skin may occur as a symptom of hysteria, and points out that from the published accounts of such cases with which he is acquainted, an artificial origin cannot be excluded with certainty.—*Brit. Med. Jour.*

Pneumonic Plague treated by large Doses of Carbolic Acid.

J. BELL (*Lancet*) says:—A case of this disease ended in recovery in the Government Hospital at Hong-Kong. This form of plague is very fatal, and the writer knows of no case of recovery in Hong-Kong. The patient, a healthy man, aged 24, was admitted suffering from gonorrhoea. His temperature was 101 degrees, and, save for the local condition, he seemed well. Gradually he became extremely ill; three days after admission his temperature had risen to between 105 degrees and 106.4; he became apathetic, delirious, with dry, furred tongue and quick pulse; coarse râles developed in both lungs, with expectoration of thick, bloody sputum, which was found to be full of typical bacilli. A diagnosis of plague was made. There were no buboes.

Hypodermic injections of digitalis and strychnia were given every four hours, and 12 grains of pure carbolic acid in solution were given every three hours.

On the next day there was a marked change for the better. The temperature slowly fell to 102 degrees, and only rose to 103.4 degrees in the evening. The tongue was moister, the pulse became less rapid, and gained strength. Bacilli were still in the sputum.

Temperature became normal three days later, the lungs cleared up, the sputum ceased. Injections were given less frequently as symptoms abated. The carbolic acid was decreased after 48 hours to four hourly doses, and was stopped on the day the temperature fell to normal.

Convalescence was rapid. The disease was contracted some 14 days before admission to the hospital. The effect of the carbolic acid was most marked; 280 grains were taken without causing toxic symptoms.

Delirium Tremens in Moderate Drinkers.

REFERRING to a paper by Dr. ELMGREEN, of Milwaukee, in the *Medical Times*, in which he reports cases of delirium tremens in moderate consumers of alcohol, FRITCHARD concludes that the symptoms of delirium tremens, etc., are due in these cases to uremia coming from kidney disorders. His conclusions are stated as follows: (1) A renal disturbance is a constant accompaniment of uncomplicated delirium tremens. (2) The relation of time between the renal disturbance is an acute nephritis, which, as a rule, probably develops without any preceding chronic nephritis. (3) The course of the renal disturbance follows so closely, step by step, with the delirium, that there is good ground for assuming that there is a genetic connection between the two phenomena. (4) There are so many similar points in the two states which are notoriously brought about by an insufficiency of the renal functions—uremia and delirium tremens—that there is reason to assume that the delirium is an acute auto-intoxication-psychosis as a consequence of the insufficient kidney function, which is due to the acute nephritis. (5) The peculiar form that this psychosis takes on is dependent upon its developing in chronic alcoholics. (6) There is a probability that delirium tremens in pneumonia is dependent, not on the pneumotoxins directly, but on the always present renal lesion. He says finally that he has examined the urine of quite a number of beer and whisky drinkers, and finds that, when in average health, their kidneys are not quite normal, the urine being thin with a slight trace of albumin, a little renal epithelium and occasionally casts, if they are a little under the normal. If they take cold, the condition is aggravated. He doubts whether the cases in delirium tremens were normal before the attack, and whether the renal insufficiency actually developed on such virgin soil as assumed by RANTZ, who has studied the subject in *Hospitals Tidende*.

SURGERY.**Sterility in Man.**

R. BISS has made a study of sterility in the male, paying special attention to azoospermia due to obstruction in the system of sperm channels. He makes two classes of cases, according to the presence or absence of changes in the cellular tissue surrounding the seminiferous tubules. The most marked of these changes is the formation of a zone of hyaline tissue around the seminiferous tubules in the place of the normal flat connective-tissue cells which form the physiological sheath of the tubules. This zone of hyaline tissue cuts off the epithelium from its supply of nourishment, normally derived from the blood-vessels of the inter-tubular connective tissue. Degenerative changes of the epithelium accompany the formation of the hyaline rings. Where the hyaline zone is thin, we find the epithelium of the tubule either normal, even containing spermatozoa, or the spermatozoa are absent and we find only a few layers of epithelium, or even only one layer, the border-lines between the cells frequently becoming indistinct. There is, however, a distinct cavity of the tubule, which is sometimes filled with spermatozoa. With the further encroachment of the hyaline zone, the epithelium is reduced to a very thin, flat layer, resembling endothelium, and these tubules contain nothing but a few fragments of cells. In the most pronounced cases the lumen of the tubule disappears completely, and instead of a channel lined with epithelium, nothing is seen but a more or less wavy and hyaline mass of tissue with very few nuclei, without any trace of the normal testicular epithelium.—*Medical Times and Hospital Gazette*.

Subarachnoid Injections of Cocaine as a Substitute for General Anesthesia in all Operations below the Diaphragm, with Report of Nine Cases.

JOHN B. MURPHY says that an American, DR. LEONARD CORNING, demonstrated in 1884-85 that anesthesia could be produced in this way. OBENST, BIER, and others later took up the matter, but the man who really advanced it as a practical anesthetic is TUFFIER. The advantages of the procedure are: Ease of application; thorough analgesia of all the tissues below the diaphragm; the retention of the sense of touch; absence of the reflexes; consciousness of the patient; avoidance of the primary, intermediate and secondary sequences of the anesthetic, as cardiac phenomena, pulmonary lesions, and renal disturbance. Whether the cocaine will be found to interfere with the function of other organs time alone must determine. TUFFIER, in his extensive experience from last November to the 10th of August, has had no untoward results of any kind, and has secured complete analgesia in every case. Hysterectomies, salpingectomies, nephrectomies, pylorectomies, cholecystotomies, and operations of that class are performed by him regularly in accordance with this method. The author gives the technique of the method, and reports nine cases of his own.—*Chicago Clinic*.

Venomous Snakes, their Bites, and how to treat them.

JOSEPH McFARLAND says that, briefly outlined, the treatment of snake-bite is (1) immediate interruption of the circulation of the bitten member, so as to prevent absorp-

tion of the poison; (2) free incision and enlargement of the fang wounds and forcible suction to extract the poison; (3) hypodermic injection of three to six drops of a fresh ten per cent. watery solution of chloride of calcium into about a dozen different areas about the wound; (4) strychnine given hypodermically to stimulate the respiratory centre; (5) immediate and frequently repeated hypodermic injections of 10 to 20 c.c. of the antivenomous serum, or, as CALMETTE calls it, "antivenene." The most urgent need of the patient is for the immediate, unlimited administration of antivenene. It would be a wise precaution for persons, whose travels or occupations keep them in continual danger of snake-bites, to provide themselves with the remedy and carry it with them. There are many whose occupations of berry-picking, lumbering, mining, hunting, engineering, etc., carry them into wild and snake-infested countries, to whom the possession of a snake-venom antitoxin with even a limited application would come as a boon.—*International Medical Magazine*.

"Thimbles" for Massage and Stripping of the Seminal Vesicles.

J. R. EASTMAN thus describes an instrument he has devised and the method of its employment. The thimbles imitate in shape the slightly bent finger, and are of nickel-plated brass three inches long, thus adding about an inch and three-quarters to the length of the massaging fingers. The distal end is broadened to the width of an inch and swells rather flatly in its full breadth from the palmar surface. The patient stands with knees straight and body slightly bent forward at right angles, and the instrument is introduced with the palmar surface of the entering finger upward, the concavity of the thimble toward the sacrum. When the instrument has been gently introduced as far as possible, the perineal muscles having become relaxed, the finger and thimble should be so turned that the palmar surface of the finger faces the bladder. The broadened and projecting anterior face of the distal end of the thimble will now rest high up on the body of the vesicle or above it.

While gentle pressure is maintained, the thimble should be drawn slowly forward along the line of the vesicle with counter-pressure over the abdomen. By passing the instrument successively backward and forward, the vesicle may be thoroughly emptied.—*New York Medical Journal*.

Post-Operative Irrigation of the Bladder.

By continuous irrigation after suprapubic cystotomy, danger of infection and infiltration of urine is obviated. The wound heals by first intention, and if the bladder is painful, the hypersensitiveness is diminished. DAXDER related at the International Medical Congress that the recovery was surprisingly rapid in the two cases he described. The wound was sutured except where a GUYON-PERRINS tube was inserted, bringing the water from a reservoir above, the flow regulated by stopcocks. A Nelaton with irrigator was introduced into the bladder through the urethra, and the irrigation continued for four to six days.

OBSTETRICS AND GYNECOLOGY.**Prevention and Treatment of Post-partum Hemorrhage.**

DR. J. W. BYRNS says:—The causes of post-partum hemorrhage may be grouped under two heads: (a) Hemorrhage due to uterine atony; (b) wounds of the parturient canal without any necessary inertia. The great majority of cases come under (a). Among the conditions which lead the accoucheur to suspect the onset of post-partum hemorrhage are: (1) History of hemorrhage at previous confinements, rapidly succeeding pregnancies, want of excretion, elderly primiparae and pre-existing metritis. (2) Over-distention of the uterus, myomata, etc., preventing contraction, albuminuria, extreme mental depression and excitement of the vascular system. (3) Strong, quick pains in the second stage of labor, with long intervals and a rapid, jerking, low-tension pulse. The use of chloroform has no effect in causing post-partum hemorrhage. The two measures which should be adopted in every case to prevent post-partum hemorrhage are: (1) The proper management of the third stage of labor; and (2) the important principle never to deliver in the absence of pains. As to actual treatment, the first measure to be adopted is external uterine massage, followed in order by the hot-water douche, introduction of the aseptic hand into the uterine cavity for the removal of the placenta or clots, and gauze plugging of the uterus. The author does not approve of bimanual compression or of the injection of perchloride of iron. He has had no experience with the method of checking hemorrhage by the drawing downward of the uterus with tenaculum forceps. All wounds and lacerations should be stitched up. The subsequent anemia, if severe, should be treated by saline transfusion direct into the veins.

Myoma, Missed Labour, and Placenta Prævia.

HARTZ, Carlruhe (*Monatschr. f. Geburtsh. u. Gynäk.*, Berlin), relates the following case:—Towards the close of the second pregnancy of a woman, known for more than two years to have a myoma, shortly after a slight hemorrhage, the membranes ruptured, although there had been no pains. The edge of the placenta was felt through the internal os, which just admitted the finger. The myoma lay close to the brim, causing some deviation of the presenting head. Three days later the child died. Eighteen days after the membranes broke, during which time there had been practically no labour pains, it was decided to empty the uterus. On examination, it was found that the tumour had been partially forced into the slightly dilated os, forming an absolute impediment to delivery. The tumour was encapsulated piecemeal, and the mouth of the womb divided. Traction on the head failed, and an arm was brought down, but had to be amputated before the macerated foetus could be delivered. The placenta, which was found to be partially adherent, was removed and the cervical wound repaired, the patient making a good recovery.

Rectal Irrigation in Gynecology.

HYDE (*Amer. Gynec. and Obstet. Jour.*) mentions a number of cases exemplifying the value of rectal irrigation. Prolonged doubling lessens the normal vaginal acidity, which is avoided by rectal irrigation, which is also of

value as a substitute for vaginal douches in young girls, except where the vaginal douche is necessary for purposes of cleanliness. It has proved very satisfactory in acute and chronic ovarian and tubal fistulas, except possibly pyosalpinx, and in obstinate intestinal paralysis with sepsis after operation, repeated enemata and the free use of cathartics failed and recovery was doubtful. Six gallons of water at 115° F., injected into the rectum, made the intestines respond slightly after the second gallon, and strongly during the remainder of the injection. Large quantities of gas were evacuated, the patient became restless, and the pulse and temperature fell. Recovery was prompt. The dull, aching pain and distress in the pelvis, and slight tympanitis, sometimes following some pelvic operations, may be relieved by rectal irrigation, which is also useful in intestinal colic, and may be relieved in the same way.

Stitch Abscesses.

HOWARD LILIENTHAL says:—Do not always blame your suture material whenever you get a so-called stitch abscess. The great majority of these are not at all due to the sutures, but to the fact that there has been an infection due to the existence of noxious organisms in the deeper cutaneous layers, which cannot always be removed by the most thorough and most conscientious scrubbing. Careful washing with green soap and alcohol, followed by a large wet dressing of bichloride applied the day before an operation, will greatly diminish the number of these generally mis-called stitch abscesses.

Operative Treatment of Complete Prolapse of the Uterus in Elderly Women.

DR. A. LAPHORN SMITH, in the *Maritime Medical News*, comes to the following conclusions:—(1) That a woman suffering from procidentia or prolapse of the uterus out of the body, though not in much pain, is yet very miserable. (2) She is in some danger, owing to the cervix becoming ulcerated and the ulceration frequently becoming cancerous. (3) It is a mistake to think that she is too old to undergo an operation because she is forty-five, or fifty, or even seventy-five years of age. (4) Elderly women support the operations remarkably well; the operations require only from twenty to thirty minutes for performance; and even if we knew that the patients were going to live only a year afterward, it would be well worth while operating for the sake of the comfort it affords them. (5) The operation of vaginal hysterectomy is especially easy and safe in these cases, having not more than one per cent. of mortality and probably not even that. (6) Ventrofixation gives good results when the uterus is short, but fails when it is long. In some cases the vagina and bladder pull down and elongate the cervix after the foetus has been firmly attached to the abdominal wall. (7) In either case, whether hysterectomy or ventrofixation be employed, it should always be followed by an anterior and posterior colporrhaphy. (8) These patients should remain in bed for six weeks after their operation, in order to give time for the new tissue to become strong.

PHYSIOLOGY, PATHOLOGY, AND BACTERIOLOGY.

Role played by the Spleen in Pancreatic Digestion of Proteids.

HENRY F. BELLAMY says:—First noticing the experiments of SCHIFF, which seem to indicate that the splenic function is essential to the formation of trypsin in the pancreas, and the apparent contradiction to this from HEIDENHAIN'S discovery of the zymogens together with the later investigations of HERZEN, which confirm in a measure the ideas of SCHIFF and seem to indicate that the spleen furnishes the product of internal secretion causing in the pancreas the transformation of inert zymogens into active trypsin, BELLAMY next proceeds to notice the criticisms of LUBSANA and others of HERZEN'S views, and especially those of POPPELSKI, and points out their weakness. Extirpation of the spleen apparently produces in animals no serious disadvantage, but the actual loss according to HERZEN'S results is that there is almost complete cessation of proteid digestion by the pancreas, this function, being in such cases almost entirely performed by the stomach. The question as to the destiny of the zymogen which the pancreas continues to elaborate is answered by the suggestion that it becomes gradually transformed into trypsin by oxidation and other agencies along the intestinal tract. It has been noticed that the spleenless animals require more food, which can be explained not only by the loss of direct proteid substances in the alimentary tract, but also in that the para-pancreas normally going on to the duodenum to be converted into true pancreatic juice are, owing to the breakdown of the pancreas, no longer capable of being absorbed and assimilated by the organism. The stomach and pancreas, therefore, so far as the digestion of proteids is concerned, would appear not only to be in direct harmony with each other in the intact organism, but also if from any cause one or the other is thrown out of action, its work is assumed and efficiently carried on by the survivor.—*The Lancet*.

Some Experiments of the Relation between Audition and the Circulation of the Blood in the Head.

HAMILTON STILLSON relates some of his personal experiences in hearing. His left ear had for a time a slight tinnitus with slight lowering of hearing-acuity. The tinnitus was caused by tubal oedema. The writer then speaks of palpating the tube by means of the tongue thrust into the post-nasal space. Focusing the attention on the tinnitus would increase its intensity, and brushing the hairs at the external orifice of the auditory meatus would cause a different tinnitus—caused by the contraction of the muscles in that vicinity. Pressure on the mastoid bone increased the tinnitus and raised its pitch. Pressing against the mastoid tip of the tinnitic ear caused it to hear objective sounds louder and in a slightly higher pitch. Lying down increased the tinnitus and lessened the hearing-distance. With head suspended, in the tinnitic ear the hearing-power seemed at first slightly diminished and then increased, but no rhythm in the objective sound could be noticed. Moving the head to and fro in its vertical axis caused a peculiar bell-like tinnitus in both ears, more noticeable in the tinnitic one.

Pathology of Alcohol.

G. ROSENHELD says:—Twenty dogs were given alcohol on an empty stomach in doses from 12 to 27 c.c., continued for a long time. In every case in which more than four doses had been administered the liver was found in fatty degeneration, the fat constituting 17 to 38 per cent. of the organ. In a parallel series of tests, 60 gm. of sugar were administered with 35 to 30 c.c. of alcohol, and there was no fatty degeneration nor other symptoms of intoxication. The fat in the liver was even less than normal in this case.—*Centralblatt f. Inn. Medicin*.

Biological Studies with References to Pathology.

THEO. KLINGMANN experimented with spirogyra threads by placing several in water in which was immersed a piece of copper foil. A control of plain water was used. In the copper water the first change noted in the spirogyra was the cessation of the protoplasmic streaming, the protoplasm becoming granular, while the division of the protoplasmic cylinder and the granular evolution in the protoplasm followed, together with retraction of the outer part of the tube and destruction of the chlorophyll bands. The same pathological conditions can be brought about by the action of various bacterial toxins and toxic blood-serum. Of one hundred and fifty cases about one-third of the patients were in perfect health, the other two-thirds being patients suffering from various disorders, such as epilepsy, neurasthenia, hysteria, mania, pyæmia, pneumonia, syphilis, tuberculosis, erysipelas, typhoid fever, diphtheria, measles and other infectious diseases, alcoholism, gout, and rheumatism. After the blood has been obtained, it is diluted with 20 c.c. of water and thoroughly mixed; a few drops of the liquid are placed on a clean glass slide; a thread of spirogyra is put into this, and is observed under the microscope with about a No. 8 LEITZ objective. The water which is used for diluting the blood is tested by placing a few threads of spirogyra in a glass dish containing some of the water, and is allowed to stand a short time. If the water is non-toxic, the specimen is not altered. The time in which the alteration takes place varies directly with the amount of toxin and the species of spirogyra. While changes in the spirogyra take place in the toxic blood solution, the blood of healthy individuals yields negative results.—*Amer. Jour. of Med. Sciences*.

Some Observations on Renal Casts.

WALTER E. TOBIE says that since the centrifuge has come into more general use hyaline casts are found in many instances in which neither clinical history nor chemical examination would seem to point to their presence. Certainly there is no good reason for believing kidney disease to be increasing to the alarming extent that microscopical examination of urine might imply. Inasmuch as hyaline casts may be present for many years without symptoms pointing to their existence, these questions naturally suggest themselves: Is the mere presence of hyaline casts necessarily a grave omen? May not the disease be checked or even of itself cease to advance? May not hyaline casts be present in urine from kidneys whose excreting functions are practically normal?—*Boston Medical and Surgical Journal*.

Diphtheria Bacilli in Healthy Throats and Noses, with Report of Cases.

FRANCIS P. DERRY thus sums up the points which he especially wishes to emphasise: (1) Diphtheria bacilli are seldom found in the throats of those who have not been exposed to diphtheria. (2) The bacilli are more frequently found in those who have been exposed, especially in those living under poor hygienic conditions or in institutions. (3) The conditions of institution life which favor the growth of the bacilli in healthy throats are the living together of a large number of persons in a limited air space. (4) Healthy individuals with virulent bacilli in their throats can spread the disease. They are just as dangerous as mild or convalescent cases of diphtheria, and ought, therefore, to be detected and isolated. (5) Cultures ought to be made among those who have been exposed to diphtheria—(a) by physicians among the members of a family who have been exposed, (b) by inspectors in the schools, (c) by health officers under any circumstances when they think the disease is being, or may be spread by such individuals.—*Boston Medical and Surgical Journal*.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Essential Conditions for Habitation to Develop and Maintain Healthful Family Existence.

ROSA ENGELMANN makes a plea for the detached suburban home with its wholesome atmosphere as compared with even the model tenement of the city. No parks, public baths, or playgrounds can take the place of the open life out of town. Rapid and cheap transportation is one of the crying problems of the day, and should be made a political issue just as much as are sanitary environment, shorter hours of labor, etc. The dwelling places of the poor of Chicago are described and contrasted with what might be offered outside the city and its slums.

Cleansing of Teeth.

THE mouth is first to be rinsed, in order to remove coarse, loosely-adherent remains of food. The brush is next moistened; some mouth-wash is held in the mouth; the edges of the front teeth are brought together, and their external surfaces brushed up and down. The external surfaces of the molars are also to be brushed, especially in this way, from above downward.

The mouth is next to be widely opened, and the grinding surfaces of the bicusps and molars are to be brushed from before backward and from left to right. The inner surfaces as well as the interstices and angles of improperly implanted teeth are then to be cleansed.

The gums are, at the same time, to be freed from any deposits. The brush is then to be turned outward, and the mucous membrane of the cheek and the folds between them and the jaws cleansed. Finally, the tongue is brushed.

The dead superficial epithelial cells of the tongue, together with mucous, saliva, and bits of food, constitute the so-called "coating" of the tongue. Many persons use "tongue-scrappers" for the removal of this coating. The advantages of these tools are as doubtful as they are unappetising. The coating can be much more thoroughly and safely removed by the aid of the brush. Any tendency to nausea which may be provoked in the beginning quickly ceases.

It is of the utmost importance to accustom one's self to retain a mouthful of water in the mouth while using the brush, in order that the product of brushing may be immediately taken up by the fluid, and not simply pushed hither and thither, as is the case when the teeth are brushed with the mouth empty.

If while brushing the teeth air is slowly inspired through the mouth, the head properly inclined, and a suitable small brush employed, the advantages of the above-mentioned process will soon be apparent.—C. ROSE (*Dental Cosmos*).

Do You Breathe Right?

THE way a person breathes is a reliable index to his or her vitality. Large, thin nostrils, slow and deep respirations, are significant of pure blood and staying powers.

Correct breathing is both thoracic and abdominal. Not only are the lungs well ventilated during inspiration, but the abdominal walls expand, altering the position of all the organs, making changes in their blood-supply, exercising the muscular elements in the bands which attach and hold these organs in position, and in this way modifying tendencies to congestion, relaxation and prolapse.

Take a deep breath, and you will note that the abdominal organs slightly shift their position followed by a feeling of increased comfort and lightness.

Breathing should always be done through the nose to ventilate the chambers in the head, and keep them in health,

as well as to warm and purify the air before it passes over the more delicate laryngeal and tracheal mucous membranes.

The body should be held erect, a slight bending forward at the hips, and the chest braced, with shoulders thrown back and head up, as though the individual were suspended from the ceiling by a hook in the breast bone. This may seem uncomfortable at first, but soon becomes habitual. The sense of increased vital power is well worth the trouble of acquiring a proper carriage.

Concentrating the attention on any task interferes more or less with respiration. It becomes less frequent and more shallow. In time, a sense of constriction around head and chest, with restlessness, develop. This may be avoided to a great extent by periodically stopping work, stepping outdoors or to an open window, and breathing deeply and slowly for five or ten minutes.

This practice is warming, and will often alleviate insomnia. It promotes digestion, and tranquillises the nerves. It will often check an irritative cough. It will freshen the complexion and brighten the eyes. As a general tonic and vitaliser to improve function and consume body waste, the practice of deep, full-breathing, cannot be too highly commended.

Learn how to breathe, then make a business of the practice at regular intervals. Just as you brush your hair or clean your teeth. Don't make your lungs sore, your head giddy, by temporary excess of enthusiasm, and then abandon your efforts in disgust. A small beginning and gradual increase into perfected power is the right rule.

General Libel.

A VERY interesting libel case was before the Central Criminal Court on Tuesday. Mr. PETER ANDERSON GRAHAM surrendered to his bail on an indictment charging him with maliciously publishing a false and defamatory libel of and concerning the sanitary inspectors of England. The alleged libel appeared in a book called "The Revival of English Agriculture," in which the defendant had made charges against sanitary inspectors as a class. In the course of this book Mr. GRAHAM stated that these gentlemen exhibit laxity and corruption in the discharge of their public duties; he said they are guilty of winking at milk adulterations, and levying blackmail on milk-vendors. The legal proceedings were taken by the Sanitary Inspectors' Association, and their Council said they would offer no evidence and allow a verdict of not guilty to be returned, as they understood Mr. GRAHAM was prepared to withdraw his imputations, express regret for having made them, and would undertake not to publish them again. The defendant's counsel agreed to this course; indeed, he could hardly have done otherwise, though it is a pity that the case was not threshed out, as it involves the very interesting problem as to whether a man can be prosecuted for libelling a community. It has generally been accepted, for instance, that a man who opens a drug-store may, without any fear of libel proceedings, seek patronage on the ground that chemists, as a class, are robbers, and sell stale drugs. If the Sanitary Inspectors' Association had been able to fight their case to a legal decision, we suppose the Chemists' Defence Association, or other chemists' association, would have taken up cudgels against one or more of those enterprising persons and proprietors of medicines who are not too scrupulous in their advertisements about how they refer to chemists generally. Some of their statements would undoubtedly, if made in respect to an individual, be actionable.—*Chemist and Druggist*.

THERAPEUTICS & PHARMACOLOGY.**Dangers of Spinal Anesthesia.**

JOHN V. SHORMAKER, in reviewing this subject, states that he has seen a single injection give rise to alarming symptoms of respiratory failure. The procedure is likewise productive of marked pain. In order to avoid this effect, BIER and others have employed BOHLER's infiltration anesthesia as a preliminary measure. In some cases chill and fever have followed the injection. Severe and long-continued headache is not uncommon. Distressing nausea and vomiting have also been excited. Exceptionally staggering gait and sharp spinal pains were experienced on the day following the injection. In some patients profuse sweating, and in others marked debility, have been noted. Numbness and tingling have occurred. In certain cases anesthesia was not produced by the operation. It need not be mentioned that the operation should be undertaken with the most rigid aseptic precautions. Great caution in the use of this method should certainly be exercised.—*New York Med. Rec.*

Amylen Hydrate in Diabetes Insipidus.

W. NIESSEN (*Therap. Monatsheft*) relates the case of a patient suffering from polyuria who was given amylen hydrate for insomnia, with the unexpected result that the symptoms of his disease at once retrogressed. Following an extensive trial, the author concludes that small doses in many cases bring about a temporary improvement in the polyuria and polydipsia and, in a few, a permanent cure, thus making this drug, among the many others, worthy of consideration. The only drawbacks are the disagreeable taste and the insolubility of amylen hydrate, which can be obviated by ordering it in capsules, to be followed by a glass of beer or wine.

Iodides in Locomotor Ataxia.

ROUX, in a recent work on the sensory visceral derangements in tabes, shows that iodide may irritate the stomach, alter the mucosa, and cause gastritis, with serious consequences. The pain is felt in the lower thorax, especially the left side, and may be severe; it is felt an hour or two after eating, increases gradually, and then disappears before the next meal. Vomiting may ensue, and persistence in the iodide may finally produce typical gastric crises. These are distinguished from true crises by their gradual onset and disappearance, by their development after gastric irritation or at the menses, and by their suppression with a milk diet and discontinuance of the iodide.—*Journal of Nervous and Mental Diseases.*

Hypodermic Injections of Pilocarpin for Gall-stones.

POPHAM (*British Medical Journal*) writes that at the suggestion of Dr. MITCHELL, of Durban, he has recently employed in several cases of biliary colic pilocarpin hypodermically in ascending doses. The results were undoubtedly encouraging, and only once did the drug give rise to any unpleasant symptoms. The writer regards pilocarpin as more efficient than morphia in hepatic colic, and attributes the good results to the increase of secretions whereby the passages are lubricated and the expulsion of the stone facilitated.

Cod-liver Oil in Tuberculosis.

M. A. F. FLICQUE speaks of the unquestioned value of cod-liver oil in tuberculous disease. Small doses must be avoided; to obtain good results, from two to three ounces

a day must be administered. If the dose of oil is shaken up in a quart of strong beer, its disagreeable taste may be overcome. The following formula is said to render the oil agreeable:—

R	Olive oil	225 grains.
	Glycerin	120 "
	Oil of bitter almonds	105 "
	Sodium hypophosphite	2 "
	Calcium hypophosphite	4 "

M.

Make an emulsion. If the oil is given fresh and cold, or with the addition of lemon or orange, its tendency to be regurgitated may be overcome. The addition of 1-80 of a grain of strychnine aids the stomach in its tolerance of the oil.

For Hemorrhoids.

R	Vaseline	3i.
	Muriate of cocaine	gr. xij.
	Morphine	gr. vi.
	Calomel	gr. xl.

M. S. Apply locally night and morning. If itching is severe, apply menthol, one drachm to an ounce of vaseline.

—JOSEPH M. MATTHEWS.

For Dipomania.

R	Apomorphine	gr. iij.
	Tr. calumbe	3i.
	Tr. capsici	℥xv.
	Tr. nuc. vom.	3i.
	Tr. cinch. comp	3iss.

M. S. Small teaspoonful after meals in water.

—*Cronica Medica.*

Miraculous Cough-mixture.

MIRACULOUS cough-mixture is made as follows:—

Ac. sulph. arom.	3ss.
Vin. opii	3vj.
Vin. antimon.	3vj.
Syr. rheades	3vj.
Spt. chloroformi	3i.
Syrupi	ad 3xx.

The dose is a teaspoonful sipped occasionally.

Chronic Coryza in Infants.

R	Bismuth. salicylic.	aa 4
	Sodii benzoat	1-50
	Orthoform	0-50
	Menthol	0-50
	Talc	10

M. S. Insufflation.—*Le Progrès Médical.*

Ulcer Ointment.

ULCER ointment, which is so very effectual, may be made as follows:—

Hydrarg. sulph. rub.	gr. ij.
Zinci oxid	3ij.
Acid. carbolic	℥xxx.
Vaselin	3ss.
Lanolin.	3iss.

M.S.A.

Correspondence.

THE STUDENTS OF THE CALCUTTA MEDICAL COLLEGE AND L. M. Ss. LET LOOSE FROM IT.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—With reference to your remarks on the letter of a medical student headed as "How Students fare in the Calcutta Medical College," published in your issue of the 12th instant, I beg to observe that though the Calcutta Medical College was started by English officials, yet it cannot be denied that both the College and the Hospital are mainly supported by fees collected from native students and by donations and subscriptions from the natives. Not only the Medical College, but most of the other Colleges and Schools were first started by English Missionaries. In short, we owe our present state of advancement in the knowledge of the English language and of all the Western sciences to the British Government and to the British public, but that does not alter the significance of the points raised in the said letter, nor can that be cited as a reason for not treating native students with impartiality. When the qualifications for entering into the Calcutta Medical College were raised from the Entrance standard to the F. A. of the University, many students then got their admissions into the Medical College with a double purpose of going up for the B. A. examination, and at the same time of securing the requisite percentage of lectures in the Medical College for going up for the M. B. examination in the event of their failing to pass the former one, more facility to which purpose was given to them by the mode of lecturing in the Medical College than in other Colleges. These students would not, therefore, care much for their medical studies, at least for the first two years, so they were merely like birds of passage, ready to fly away on the advent of proper time. The introduction of the new rules for promotion by Dr. BOMFORD, by making a certain percentage of marks in each subject compulsory, efficiently checked the ingress of such students into the Medical College, and so far these rules had a salutary effect. At present, however, no student gets admission into the Medical College who is not earnest in his medical studies, so to raise the percentage of marks nearly to the University standard in the College examinations is now wholly uncalled for, and it looks nothing less than shutting the doors of the Medical College against the native students, for it will certainly tell much on the constitution of our young medical students to pass an examination each of the five years of their college career, which is unparalleled in any other college or country. I cannot agree with you that this highest possible standard of results at examinations, as you call this high-handedness of Dr. BOMFORD, will make better medical men of our students, and that it will prevent some stupid L. M. Ss. from coming out of the Calcutta Medical College. I cannot say that by raising the general standard of qualifications for entrance into the Medical College from the Entrance examination of the Calcutta University to the F. A., the Calcutta Medical College has sent any better medical men to the public than it or any other Indian Medical College has done before. On the contrary, it will surely let loose lots of

unqualified medical men on the public, for those students who enter the Medical College after passing the F. A. examination of the Calcutta University cannot, after one or two years, change the profession they sought to learn. The result will be that on failing to get promotion for a year or two they will cease to be regular students, and try to learn the profession by becoming extra-students.

You say that the Calcutta Medical College has let loose some stupid L. M. Ss. on the public. I dare say that even the Universities of Europe let loose no less stupid M. Bs. or M. Ds. occasionally. In my student days, while I was a clinical clerk in Dr. CHAKRAVARTY'S ward, one day Dr. CHAKRAVARTY having been prevented by illness from visiting his wards in the hospital asked the resident physician to see his patients. This resident physician was a young M. B. of the London University and held a senior Professorial Chair in the College and afterwards became one of the distinguished physicians in Calcutta. He prescribed plumbi acetat and acid sulph dil combined in the same mixture to a patient suffering from profuse hæmoptysis. Had not the house physician, a native Assistant Surgeon, pointed out to him the incompatibility of the mixture, for which he received thanks from the resident physician, the man would have probably died from bleeding.

From your remarks on the notorious "Stone" case of the Medical College Hospital, it would seem that, had the man's bladder been found coated with calcareous deposits, the mistake committed in diagnosing this case as one of vesical calculus might have been forgiven, even to a "Professor" of Surgery, while Professors FAYRER and CUTCLIFFE would most emphatically direct their students to bear in mind that they should not only feel the stone, but they should hear it, for no coating of calcareous matter which may be mistaken for a calculus can elicit a sound like a stone striking against a steel sound. I mention these two cases, not with the intention of disparaging any of these gentlemen, but only to show that it is not at all strange that some L. M. Ss. of the Calcutta Medical College should sometimes seem to be very stupid even in some trivial matters. There is a proverb in the Sanskrit language that "a man who has killed a hundred patients may be classed among physicians, but one who has killed a thousand ones is only to be called a healer of ailments." However, if really some stupid L. M. Ss. come out of the Calcutta Medical College, the fault lies more with the manner in which professors are appointed in it, as well as with the Examiners and the University authorities. In the first L. M. S. examination held in April last, Dr. GIBBONS allotted three-fourths of the marks set apart for practical examination in *Materia Medica* to identification of ten specimens of drugs, and only one-fourth to Practical Pharmacy; so many students, who were successful in identifying six or seven specimens of the drugs, by fair or foul means, but got no marks in Practical Pharmacy, must have passed, while those who got 50 per cent. of marks in Practical Pharmacy, but failed to identify a single specimen more of the drugs, got plucked. In the same manner a student who gets good marks in identifying instruments, but no marks in Operative Surgery, might also pass. Is it then to be wondered that some stupid L. M. Ss. should come out of the

Calcutta Medical College, and is it not probable that even in spite of Dr. BOMFORD's raising the percentage of marks in the class examinations such stupid L. M. Sc. will sometimes still slip out through his fingers!

Yours, &c.,
AN L. M. S.

Dated the 31st December 1900.

(Our correspondent's excellent letter deserves the attention of the College authorities.—ED., I.M.R.)

BRUSSELS M. D.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—I shall be thankful if you will kindly allow me to state what I know of the above degree. A correspondent once asked the Editor of the British *Lancet* whether the *Licence* of an Irish Corporation is superior, as many in Ireland believed, to the medical *Degree* of England; to which the editor replied that it is a baseless opinion, however natural such an opinion might be in Ireland.

It appears to me, after reading the strictures of "M. D." on the Brussels degree, that the above self-complacent disparagement of others has been carried too far by "M. D." The following facts regarding the Brussels degree ought to disabuse his prejudiced mind:—

(1) Brussels M. D. is conferred after an examination conducted by nearly 14 or 15 Examiners on as many subjects, most of which are the advanced subjects of the profession. The examination is both oral and practical, and has been pronounced by the *Lancet*, the leading medical journal of England, as being "undoubtedly a good one" (*vide Lancet*, March 5, 1898, page 652), and also equal to the M. R. C. P. of London (*vide Lancet*, July 15, 1899, page 194).

(2) The *Lancet* says in the same place that this degree "is a good one, held by many practitioners of high standing." There are over 700 practitioners in England holding this degree, some of whom—as Doctor MATHEWS DUNCAN, the great obstetrician, and Doctor WILLIAM MURRELL, the great therapist—are well-known professors in London colleges and authorities in their respective departments.

(3) It is a stern fact, notwithstanding the show of philosophic doubt on the part of "M. D.," that a good many of the admittedly sound British diplomates (M.R.C.S., L.R.C.P., &c.) do get plucked in the examination. The latest figures are five failures out of nine.

(4) This degree has been acknowledged and entered by the General Medical Council as a *bona fide* foreign distinction. "M. D." might profitably spare a part of the contempt which he now professes to feel for the Brussels degree, for the prejudices and narrowness shown by certain cultured critics.

Yours, &c.,
NOT A BRUSSELS GRADUATE.

BOOK REVIEW & TRADE NOTICES.

MATERIA MEDICA FOR INDIA.

BY C. F. PONDER, M.B., C.M., AND D. HOOPER, F.R.S., F.L.S.

(Published by Thacker Spink & Co., 1901. Price Rs. 6.)

We have gone carefully through this book of 365 pages, and have failed to discover any special reason for its publication. Everything found in it is to be found in other books, and much that is to be found in other modern books is not to be found in this. If the object of the compilers was simply to put together in one book all the drugs and preparations of the British Pharmacopoeia that are to be procured in some form or other from indigenous dealers in India, then the absence of fuller details is a serious drawback. To present the student, or the Indian practitioner, with so incomplete a work on Indian drugs is simply to create confusion in his mind. The price, six rupees, is too tall for such a book. We venture to offer the suggestion that if the authors ever desire to make a second edition of their work, they should consult some experienced Indian practitioners, since neither of them can be credited with Indian "experience."

Messrs. ALLEN AND HANBURY, LIMITED, are introducing to the medical profession a new preparation named Byno-hæmoglobin, which is a combination of pure hæmoglobin prepared from fresh blood by special processes with their fluid extract of malt, Bynin, one dram of hæmoglobin being present in every ounce of the preparation. It contains 0.16 per cent. of iron in organic combination, and has no added iron present. The hæmoglobin is dissolved in the Bynin, and nothing additional is introduced, so that the blood-forming powers of the former are associated with the digestive and strengthening properties of the latter. It constitutes a thick, dark-red fluid of a very sanguineous look when dissolved. It contains a large amount of albumen, and reacts strongly with guaiacum and ozonic ether. Doubtless it will prove a most valuable remedial agent for those who can get over the nauseating idea associated with its blood-like appearance.

BURROUGH'S AND WELLCOME'S MEDICAL DIARY FOR 1901.

This handsome, handy and exceedingly useful Diary comes as a real boon to the medical practitioner. It simply puts all other medical diaries into the background by furnishing a large fund of the most useful information to the busy medical man. As a *visiting day book* it is most convenient. It is to be had from Mr. Charles W. White, Bombay.

Government Medical Gazettes.

BOMBAY.

Lieut.-Col. W. G. H. Henderson, F.R.C.S., I.M.S., is apptd. to be a nominated commr. of the Poona Suburban Municipality, *vice* Lieut.-Col. J. P. Greany, M.D., I.M.S., resigned.

Lieut.-Col. C. F. Willis, I.M.S., is apptd. to be a nominated commr. of the Malcolmpeth Municipality in the Satara Dist., *vice* Lieut.-Col. D. C. Davidson, I. M. S., resigned.

Capt. S. Evans, M.B., I.M.S., and Major John Grimmin, V.C., I.M.S., respectively delivered over and received ch. of the office of the Health Officer of the Port of Bombay on 16th Nov, 1900.

CENTRAL PROVINCES.

The following transfers are ordered among Civil Hosp. Assts.:-

Balwant Lakshman, doing duty at Nagpur, to Janjgir Branch Dispy. in Bilaspur Dist.

Bhagwandass, from Janjgir Branch Dispy. to Pachmarhi Civil Dispy.

Abdul Aziz, from Pachmarhi Civil Dispy. to duty at Jubbulpore.

Civil H. sp. Asst. Baliram, doing duty under the orders of the Civil Surgn., Nagpur, to the Sindi Branch Dispy. in the Wardha Dist.

Civil Hosp. Asst. Binode Behari Burdhan from the Sindi Branch Dispy. to the Sohagpur Branch Dispy. in the Hoshangabad Dist.

Civil Hosp. Asst. Sitaram Rupchand from the Sohagpur Branch Dispy. to the Khandwa Main Dispy., in the Nimar Dist.

Civil Hosp. Asst. Saiyid Muhammad Hyder Husain Hydri from the Khandwa Main Dispy. to the Buti Dispy., Nagpur.

The services of Civil Hosp. Asst. Kashinath Gopal being no longer required for famine duty in the Civil Dept. in the Nagpur Dist., he is directed to do gen. duty under the orders of the Civil Surgn., Nagpur.

Privilege leave for three months is granted to Civil Hosp. Asst. Kashinath Gopal, doing duty under the orders of the Civil Surgn., Nagpur, from the 17th Nov. 1900.

Privilege leave for three months is granted to Civil Hosp. Asst. Narayan Vinayak, Soman, doing duty under the orders of the Civil Surgn., Nagpur, from the date on which he is permitted to avail himself of the same.

Civil Hosp. Asst. Jagir Parshad, attached to the Jabera Branch Dispy. in the Damoh Dist., is reduced to the 2nd grade by order of the Chief Commr. for a period of six months, from the 8th Nov. 1900.

Civil Hosp. Asst. Abdulla Khan, doing duty under the orders of the Civil Surgn., Nimar, is tempy. posted to the ch. of the Patan Branch Dispy. in the Jubbulpore Dist. during the absence on leave of Civil Hosp. Asst. Saiyid Mehdi Husain.

The services of Civil Hosp. Asst. Dallava Nand Das being no longer required for famine duty in the Civil Dept. in the Raipur Dist., he is directed to do gen. duty under the orders of the Civil Surgn. there.

Civil Hosp. Asst. Bhondulal of the Mal Dispy. in the Chanda Dist. was placed on famine duty in the Civil Dept. in addn. to his own duties, from the 10th June 1900.

Civil Hosp. Asst. Ashmat Ali, on return from famine work under the P. W. D. is tempy. posted to the Behir Branch Dispy. in the Balaghat Dist. during the absence on leave of Civil Hosp. Asst. Abdul Karim.

Civil Hosp. Asst. Kharad Singh Thakur, doing duty under the orders of the Civil Surgn., Jubbulpore, held ch. of the med. arrangements at the Bharaghat Fair in that dist. from the 4th to the 12th Nov. 1900.

Civil Hosp. Asst. Srikrishna Rao, attached to the Police Hosp., Chanda, is tempy. transferred to Sironcha, to hold ch. of the Dispy. there, during the absence on leave of Civil Hosp. Asst. G. Ramiah Naidu.

Civil Hosp. Asst. Dashrath Balwant, doing duty under the orders of the Civil Surgn., Wardha, is tempy. posted to the Police Hosp., Chanda, in place of Civil Hosp. Asst. Srikrishna Rao.

Furlough for two years is granted to Civil Hosp. Asst. Ashraf Husain, doing duty under the orders of the Civil Surgn., Nagpur, from the date he is permitted to avail himself of the same.

The services of Civil Hosp. Asst. Wizarat Ali being no longer required by the P. W. Dept., he is directed to do genl. duty under the orders of the Civil Surgn., Betul, from the 9th Sept. 1900.

N.-W. P. AND OUDH.

Senior Asst. Surgn. Beni Madhab Dass, in ch. Bhinga Dispy., Bahraich, leave on med. certificate for nine months, from the 28th Oct. 1900.

Hosp. Asst. Chheda Lal, attached to the Ikauna Branch Dispy., held ch. of the Bhinga Dispy., Bahraich, during the absence on leave of Senior Asst. Surgn. Beni Madhab Dass, from the 28th Oct. to 19th Nov. 1900.

The undermentioned Civil Asst. Surgns. of the Provl. Est., N.-W. P. and Oudh, having passed the Septennial Exam. on

the 5th Nov. 1900, are promoted to the next higher grade from the dates mentioned against their names :-

Hari Gopal Chatterji, to be 1st grade from 1st Nov. 1900.

Shankar Das, to be 2nd grade from 2nd Aug. 1900.

The services of Lieut.-Col. A. R. W. Sedgfield, M.B., I.M.S. (Bengal), are replaced at the disposal of the Mily. Dept.

The services of Capt. W. H. Orr, I.M.S. (Bengal), are placed tempy. at the disposal of the Govt. of the N.-W. P. and Oudh. The services of the undermentioned officers are placed tempy. at the disposal of the Mily. Dept.:-

Lieut.-Col. Cooverjee Cawsajee Vaid, I.M.S. (Bengal.)

Major L. J. Piesani, F.R.C.S., I.M.S. (Bengal.)

Capt. H. W. Orr, I.M.S., whose services have been placed tempy. at the disposal of this Govt., to officiate as Civil Surgn., and to be posted to the Mainpuri dist.

The services of the undermentioned officers are placed tempy. at the disposal of the Mily. Dept.:-

Lieut.-Col. F. R. Swaine, M.B., I.M.S. (Bengal); Major Merwanji Karasji Cursetji Sanjana, I.M.S. (Madras); Major Hormasji Hakim, I.M.S. (Madras); Major Karasji Hormasji Mistri, I.M.S. (Bombay); Major A. J. O'Hara, I.M.S. (Madras); Major Upendra Nath Mukerji, M.B., I.M.S. (Bengal); Major J. R. Adie, M.B., I.M.S. (Bengal); Major G. B. French, M.B., I.M.S. (Bengal); Major J. Garvie, M.B., C.M., I.M.S. (Bengal); Major Kanta Prasad, M.B., I.M.S. (Bengal); Capt. S. E. Prall, M.B., I.M.S. (Bombay); Capt. E. V. Hugo, M.D., I.M.S. (Bengal); Capt. G. T. Birdwood, M.D., I.M.S. (Bengal); Capt. O. Thompson, M.B., I.M.S. (Bengal); Capt. W. D. Hayward, M.B., I.M.S. (Bengal); Capt. J. Stephenson, M.B., I.M.S. (Bengal); Capt. A. Hooton, I.M.S. (Bombay); Capt. A. W. R. Cochrane, M.B., F.R.C.S., I.M.S. (Bengal); Major J. W. Rodgers, I.M.S. (Bengal); Major F. C. Pereira, M.B., I.M.S. (Madras); Capt. J. M. Crawford, M.B., I.M.S. (Bengal); Capt. J. S. N. Lumden, M.B., I.M.S. (Bengal); Capt. Robert King Mitter, M.B., I.M.S. (Madras); Capt. H. A. Smith, M.B., I.M.S. (Bengal); Capt. D. R. Green, M.D., I.M.S. (Bengal); Capt. P. C. Gabbett, I.M.S. (Madras); Capt. C. Milne, I.M.S. (Bengal); Capt. B. B. Chatterton, M.D., F.R.C.S., I.M.S. (Bengal); Capt. T. A. O. Langston, I.M.S. (Bengal); Capt. T. Stodart, M.B., I.M.S. (Madras); Capt. E. S. Peck, M.B., I.M.S. (Bengal); Capt. E. C. MacLeod, I.M.S. (Bengal); Capt. H. M. Moore, I.M.S. (Bombay); Capt. C. J. Ryberson, M.B., I.M.S. (Bengal); Capt. A. F. Stevens, I.M.S. (Bengal); Capt. E. M. Illington, I.M.S. (Madras); Capt. H. A. F. Knapton, I.M.S. (Bombay); Capt. C. B. Harrison, M.B., I.M.S. (Madras); Capt. T. B. Kelly, F.R.C.S., I.M.S.; Capt. R. H. Price, M.B., I.M.S.

Civil Asst. Surgn. Masha Allah Khan, Lecturer on Materia Medica, Agra Med. School, and in ch. of Thomason Hosp., Agra, privilege leave for two months.

Civil Asst. Surgn. E. H. Thomas, on being relieved by Asst. Surgn. Nobin Chandra Chakravarti, Bai Bahadur, to officiate as Lecturer on Materia Medica Agra Med. School, and in ch. of Thomason Hosp. Agra, vice Asst. Surgn. Masha Allah Khan.

PUNJAB.

Hosp. Asst. Narsingh Das, Allpur Dispy., Muzaffargarh Dist., was placed on cholera duty in that dist. from the 7th to the 15th Nov. 1900. He rejoined his dispy.

Asst. Surgn. Feroze-ud-din was apptd. to do gen. duty at the Ferozepore Civil Hosp. on the 3rd Nov. 1900.

Hosp. Asst. Hafiz Ali, N.-W. Ry., Jind Section, was transferred, at his own expense, to the N.-W. Ry., Bhatinda Section, on the 29th Aug. 1900, relieving Hosp. Asst. Laxba Ram, who joined the Jind Section on the 31st Aug. 1900.

On being relieved of the ch. of the Chinot Dispy., Jhang Dist., Tempy. Asst. Surgn. Uttam Chand was placed on plague duty in the Jullundur and Hoshiarpur Dist. from the 28th Nov. 1900. vice Asst. Surgn. Udal Bhan, Imperial List, who was placed on gen. duty at Jullundur from the 1st Dec. 1900.

Hosp. Asst. Aulad Hussain was placed on gen. duty at Sialkot from the 23rd Nov. 1900.

The following 3rd Grade Asst. Surgns. having passed the Septennial Professional Exam. of Asst. Surgns. held on the 5th Nov. 1900, are promoted to the 2nd Grade from the dates noted against their names :-

Bhai Narain Singh; Munsifi Ala Jowaya.

On transfer from the Kotgarh Dispy., Simla Dist., Hosp. Asst. Hardial was apptd. to the ch. of the N.-W. Ry. Hosp., Umballa Cantonment, on the 20th Nov. 1900, relieving Hosp. Asst. Harnam Singh.

Hosp. Asst. Muhammad Ismail Khan, Garhshankar Dispy., Hoshiarpur Dist., obtained fifty days' privilege leave, and was relieved of his duties on the 1st Dec. 1900 by Hosp. Asst. Amir-ud-din, transferred from Hoshiarpur.

Hosp. Asst. Hussein Shah, Tolumba Dispy., Mooltan Dist., obtained two-months' privilege leave, and was relieved of his duties on the 1st Oct. 1900 by Hosp. Asst. Gela Ram, transferred from Montgomery.

On reversion from the plague duty, Gurdaspur Dist., Hosp. Asst. Sultan Ali rejoined the Batala Dispy. in the same dist. on the 1st Dec. 1900.

Hosp. Asst. Ghulam Rasul, Tobana Dispy., Himar Dist., was granted one month's privilege leave, and was relieved of his duties on the 30th Nov. 1900 by Hosp. Asst. Brij Lal, on itinerating duty in Hissar Dist.

Hosp. Asst. Bhag Mal resumed ch. of the Kaithal Dispy., Karnal Dist., on the 28th Nov. 1900, relieving Hosp. Asst. Sharif Hussain.

Hosp. Asst. Sharif Hussain was apptd. to the ch. of the Karnal City Dispy., on the 7th Dec. 1900, relieving Hosp. Asst. Abbas Ali, who was placed on gen. duty at Karnal.

G. O. C. C.

Lieut. G. King, M.B., I.M.S., to the offg. med. ch. of the regiment, *vice* Capt. T. E. Watson, M.B., I.M.S., proceeded on field service to China.

Capt. R. W. Knox, M.B., I.M.S., to the offg. med. ch. of the regiment, *vice* Capt. E. H. Sharman, I.M.S., proceeded on field service to China.

The undermentioned officers are granted leave out of India :—

Royal Army Medical Corps.—Maj. S. C. Philson, for three months, on private affairs.

Maj. J. O. Weir, R. A. M. C., to be Sany. Offr., Punjab Command, from 1st Oct. 1900.

Maj. L. P. Mumby, R. A. M. C., to be Sany. Offr., Bengal Command, from the date on which he assumes ch. of the duties thereof.

Maj. J. R. Forrest, R. A. M. C., to officiate as Sany. Offr., Bengal Command, from the 1st Oct. 1900, until the return from leave of Maj. L. P. Mumby, R. A. M. C.

The undermentioned officers are granted leave out of India :—

Army Medical Staff.—Surgn.-Gen. W. A. Catherwood, M.D., for six months on med. certificate.

Lieut.-Col. W. T. Johnston, R. A. M. C., for six months on med. certificate.

MADRAS.

Capt. Gerald Godfray Giffard, I. M. S., to act as Dist. Med. and Sany. Offr. with med. ch. of Central Jail, Trichinopoly, during the employment of Lieut.-Col. W. F. Thomas, I. M. S., on other duty.

Mr. Charles Arthur Lafrenais to act as Dist. Med. and Sany. Offr., Godavari, during the employment of Major A. J. O'Hara, I. M. S., on other duty.

Surgn. Lieut. William Stokes, M.B., C. M., out of India, for ten months from 1st. Feb. 1901.

The following notification of the Government of India is republished :—

Home Dept., Medical, 7th Dec. 1900.

The services of the undermentioned offrs. are placed tempy. at the disposal of the Mily. Dept :—

Lieut.-Col. S. C. Sarkies, I. M. S. (Madras).

Capt. W. C. Vickers, M. B., I. M. S. (Madras).

BURMA.

Hosp. Asst. G. Francis assumed ch. at the Civil Hosp., Mingin, Upper Chindwin dist., on the 22nd Nov. 1900.

Hosp. Asst. Mahomed Haniff relinquished ch. at the Gen. Hosp., Rangoon, on the 15th Nov. 1900, and assumed ch. at the Police Hosp., Kintat, Upper Chindwin dist., on the 25th Nov. 1900.

Hosp. Asst. Salik Ram relinquished ch. at the Civil Hosp., Mingin, Upper Chindwin dist., on the 22nd Nov. 1900, and assumed ch. at the Civil Hosp., Kalewa, Upper Chindwin dist., on the 27th Nov. 1900.

Hosp. Asst. P. C. Rai, on return from leave, assumed ch. at the Civil Hosp., Wundwin, Meiktila dist., on the 6th Dec. 1900.

Hosp. Asst. Sawan Singh, on transfer to the Southern Shan States, relinquished ch. at the Civil Hosp., Wundwin, Meiktila dist., on the 6th Dec. 1900.

Hosp. Asst. Dhanaswar Panda relinquished ch. at the Police Hosp., Lashio, Northern Shan States, on the 4th Dec. 1900, and assumed ch. of duties with Capt. Rainey's escort on the 5th Dec. 1900.

Hosp. Asst. Ghulam Mustafa assumed ch. of additional duties at the Police Hosp., Lashio, Northern Shan States, on the 9th Dec. 1900.

Hosp. Asst. Lakmi Dass relinquished ch. at the Police Hosp., Myitkyina, on the 30th Nov. 1900, and assumed ch. at the Police Hosp., Mogaung, on the 1st Dec. 1900.

Hosp. Asst. Aubaranam Pillay held ch. of additional duties at the Police Hosp., Mogaung, from the 16th Nov. 1900 to the 25th Nov. 1900.

Hosp. Asst. G. Govindasawmy Naidu relinquished ch. at the Police Hosp., Myitkyina, on the 2nd Dec. 1900, and assumed ch. of his duties with the Sadan escort on the 3rd Dec. 1900.

DOMESTIC OCCURRENCES.

[The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.]

BIRTH.

JAMES.—On December 6th, 1900, at Sunnyholme, East Cowes, Isle of Wight, the wife of Captain S. P. James, M.B., I. M. S., Lond., of a daughter.

MARRIAGE.

KNOX.—LOCH.—At Holy Trinity Church, Allahabad, on New Year's Eve, Robert Welland Knox, Captain, Indian Medical Service, third son of Mr. Justice Knox, to Lillian Margaret, third daughter of the late Colonel John Lewis Loch, late Inspector-General of Police, Central Provinces.

NOTICES TO CORRESPONDENTS.

R. Y. R. (Sunderabad).—Your paper has been received, and will find early publication.

A. D. H.—Write a week before you are leaving.

G. K. T. (Madras).—Any practitioner holding British degrees or diplomas is eligible for the Brussels M.D.

H. A. R.—The *Record* published the special leave rules for medical men employed on plague duty. See back numbers.

G. K. (Satara).—See back numbers of the *Record* for the information you need.

E. S. P. (Lucknow).—See last number.

J. T. P.—See this number.

B. M. K.—Send in your reports, and they will receive attention.

C. B. B. (Saharanpur).—Apply to the Director-General, I. M. S.

E. F. (Peshawar).—Read Council Report last number.

J. P. M. (Dholera).—Your remedy lies in showing your own special merits over the treatment of quacks.

S. M. P. (Phulera).—Apply to the Director-General, I. M. S.

E. H. C. L.—The regulations apply to M. Ps. The Entrance Examination of any Indian University exempts from matriculation for the diplomas of all the Corporations of Great Britain and Ireland.

S. K. C. (Ahmedabad).—The diplomas of L. R. C. S. and P. C. can only be obtained in England, Ireland and Scotland. Any Indian student may win them by examination. There are three bogus medical schools in Calcutta, but their certificates of qualification are empty and worthless titles. No self-respecting man can possibly care to have them.

R. K. M. (Jogati).—See back numbers of the *Record*.

M. L. V. (Aligarh).—All men and animals bitten by rabid dogs do not become rabid. Municipalities should not poison or destroy healthy dogs, but owners of dogs should not allow them to stray about when rabid dogs are rampant. It is reported that for every 10,000 cases of dog-bite, one is only a victim to rabies. Jackals and foxes become rabid, and their bites are as bad as those of rabid dogs.

T. D. T. (Vellore).—Many thanks.

ORIGINAL ARTICLES.

THE MANAGEMENT OF NORMAL LABOR, INCLUDING THE USE OF THE FORCEPS.*

BY AUSTIN FLINT, JR., M.D.,
New York.

NORMAL labor, understood in a somewhat wider sense than the strictly literal, includes the vast majority of obstetrical cases. Labor may be normal in the sense that all conditions are present that conduce to the greatest safety of both mother and child, and still may present wide variations as regards its duration, the character of the labor-pains, and various other conditions. Its proper management is perhaps more far-reaching in its effects, for good or for harm, than mismanagement in the comparatively few abnormal cases.

Of late years, advances in obstetrical practice have been made chiefly along the lines of improved methods of carrying out antiseptic and aseptic details and in obstetric surgery. Statistics as regards mortality have shown a corresponding improvement, and it is now the aim of obstetricians to show a corresponding improvement in morbidity. In hospital practice the mortality has been reduced to about one-half of one per cent. Morbidity statistics vary between four or five per cent. and as much as twenty-five per cent.

In a general way, the fewer the examinations and the less interference of any kind that is allowed, the smaller becomes the percentage of temperature cases. If we remember that a large proportion of these cases are normal at the start, as regards presentation and position, and that the large percentage of morbidity is due to some fault in the management, the most important principle in the management would be non-interference. It is not enough to conduct a case with the result that "mother and child lived," but the result should be that the mother recovered perfect health, and the baby was strong and healthy also. To make this the rule in practice requires a close and serious study, and the exhibition of a good deal of skill even in so-called normal cases. The general indication in treatment is to do everything that will limit the suffering to the smallest degree consistent with the best interests of mother and child.

In a paper which is to cover so wide a field, and which must be limited in time, a comprehensive review of the management of normal cases is impossible. It is also difficult to pick out the important details of management, and to omit other details, all of which have a direct bearing on the ultimate results. Perhaps the most direct is to give a brief review of the technique in the conduct of a case, with reference more particularly to private practice.

While not wishing to go outside the scope of the title of this paper, I believe a careful physical examination at the end of the eighth month of pregnancy is necessary, and that it partially takes the place of a similar examination at the beginning of labor. If such an examination can be made, nearly all danger of infection and subsequent fever is avoided, and very valuable information is

obtained. A diagnosis at this time will usually hold good at the time when labor actually begins, and especially in the primipara, for presentation and position rarely change during the last month of pregnancy.

The examination should, of course, include pelvic mensuration. The patient should be instructed to take daily walks during the last month of pregnancy and up to the very beginning of labor. The results of these daily walks are very satisfactory. They favor softening of the lower segment of the uterus and vagina, allow the head to sink through the pelvic brim, and lessen the liability to chance in position. The softening also renders dilatation easier, and shortens the first stage of labor.

A consideration of the management of actual labor is conveniently divided into the management of the three stages.

The First Stage.—If it has been possible to make an examination at the eighth month, the examination during the first stage is very much simplified; this examination, when the patient's condition will admit, is preceded by a warm bath, the external genitals are cleansed with green soap and water, an enema is given, and a sterilised gauze pad is placed over the vulva. After the usual sterilisation of the hands, an external examination is made, and finally an internal examination. This is done to verify the diagnosis previously made, and to ascertain the progress since the beginning of labor. It is better to make a long and careful examination at this time than to make a series of short and incomplete examinations. If the case can be diagnosed as normal, the management consists almost entirely in observation until nearly the end of this stage. The patient is allowed to assume any position that is most comfortable, the upright being preferred as long as possible. The nurse should be instructed to see that the patient's bladder is emptied at hourly intervals. Toward the end of this stage the patient should be put to bed; and in the majority of cases an anæsthetic may be used. Ether used in small quantities during each pain seems gradually to be displacing chloroform for this purpose, and it can be used in exactly the same way.

I often aid manually in the dilatation of the cervix toward the end of the stage if progress appears to be slow. The rule to preserve the bag of waters as long as possible, particularly in primipara, deserves mention. As the physician gains experience, the number of necessary examinations becomes less and less. The advantages of infrequent examinations are too well known to require further discussion.

The Second Stage.—No special intervention is required during this stage until the head reaches the pelvic floor. Time does not permit of even a brief outline of the measures designed to preserve the perineum from rupture. The principle underlying all methods is to secure the dilatation of the vulva before allowing the head to pass; and under normal conditions this takes place by a slow and regular advance of the head. An anæsthetic is of great advantage in many cases, the quantity being determined not only by the degree of suffering, but by the slowness or rapidity with which the child's head advances. Those who are accustomed to a frequent use of anæsthetics will undoubtedly be

* Read before the New York State Medical Association, 16th October 1900.

compelled oftener than others to use the forceps; and so far as the integrity of the pelvic floor is concerned, undue delay in delivery is almost as dangerous as haste.

In my opinion the use of the forceps, when the head is at the outlet of the pelvis, is too infrequent. Its proper use is an art, but an art not more difficult to acquire than the proper delivery of the head and shoulders through the vulva without the use of the forceps. The mistake of the beginner is haste. The principles governing methods of "preservation of the perineum" apply with equal force in a forceps delivery and in an uncomplicated delivery.

Time, with a slow, gradual advance of the presenting part, will produce the dilatation of the vulvar orifice exactly as it does dilatation of the cervical canal. Under normal conditions, even a small orifice will dilate under the influence of repeated advances and recessions of the presenting part, until the time comes when delivery may be safely accomplished. If this takes place from the influence of the pains alone, any interference other than regulating the rapidity of these advances is unnecessary. If the pains are too feeble to cause the head to advance regularly, they may be stimulated. The withdrawal of the anæsthetic, if one is used, or the substitution of ether for chloroform, is often all that is necessary. The uterine contractions can then be reinforced by voluntary efforts at expulsion. Occasionally a stimulant produces this effect. Ergot, of course, should never be used. As soon, however, as the presenting part ceases to advance and stimulation or withholding the anæsthetic does not cause advance, the low forceps operation is indicated. It is futile to wait any definite time in the hope that the propulsive qualities of the pains will reappear. Artificial extraction by means of the forceps is safer both for the mother and for the child than a waiting policy. The forceps should be used in imitation of normal pains. Traction should be slow, gradually, increasing in force until the soft parts in front of the head are put upon the stretch, then the head should be held for about a minute, followed by a slow and gradual relaxation of the traction force until the artificial pain has passed. A few minutes should then be allowed for a return of the circulation in the parts subjected to pressure, when the operation should be repeated.

Under the normal conditions that I am considering, delivery with an intact pelvic floor can be accomplished in a very large proportion of cases. In a general way, the same results can be accomplished by the forceps when the head has partially descended. Such operations are called median forceps operations, and are divided into two classes: (1) When the head is still within the cervix; (2) when the head is outside the cervix. In the latter instance the operation is the same as in the ordinary low forceps operation, except that the blades should be so applied that they aid the incomplete rotation. This requires a little more skill in their application, but it is usually accomplished with ease. In the former instance, with the head still within the cervix, as in high operations, the danger is great, and the procedure becomes a major operation. This should never be undertaken unless there is some special indication; and the case is then outside the scope of this paper.

Immediately after the delivery of the head, the mouth and eyes should be wiped out. The advantage of clearing the fauces of mucus before the first effort at inspiration is very great. The child is prevented from drawing mucus into its lungs; and when the mouth is cleared, as a routine practice, partial asphyxiation is very much less frequent. While apparently only a minor point, this is well worthy of more general adoption.

The Third Stage.—Personal observation of the conduct of labor cases by students has shown that the interval between the second and third stage, or the third stage itself, is the time when infection is most likely to occur. It is rarely that any internal examination is required after the birth of the child.

Before any attempt to deliver the placenta is made, the hands should be re-sterilized; clean towels are placed under the patient's hips, and the usual preparations for a possible hæmorrhage are made.

During this time the nurse maintains pressure over the fundus; and after an interval of twenty or thirty minutes the placenta is expressed. This interval may be made shorter if the uterus is firm and well contracted, or longer if the uterus is flabby. If the cord has been tied in two places, it is usual to cut the ligature or to cut off the placental end of the cord behind the ligature, so that the two or three ounces of blood which the placenta contains can escape. This reduces the bulk of the placenta and makes its expression a little easier.

After the delivery of the placenta, it is my custom to give a hot sterile douche. This stimulates the uterus to contract, cleanses the vagina of all clots, and allows a thorough inspection of the vulva and vagina. Tears that are slight are then easily seen, and can be immediately repaired. Nothing conduces to the comfort of a patient more than perfect cleanliness; and even slight tears in the vagina may be starting-points of infection. The records of cases in private practice show that, of patients who had a perfectly normal temperature during the puerperium, nearly all had no tear in the vagina or vulva. Should any laceration occur, an immediate repair should of course be made.

In this brief review of the management of normal cases nothing has been said that is absolutely new. I have endeavored merely to emphasise some of the more important points in the management which are likely to be carelessly performed by the general practitioner. The points, briefly reviewed, are:—

First.—The importance of making a diagnosis and a complete physical examination about one month before the onset of labor. This not only will give a great deal of information which may be utilized during the labor, but it affords ample time in which premature labor can be induced if there is any abnormality.

Second.—Infrequent examinations during labor. If the delivery of women could be regarded as a surgical operation, requiring as full and complete antiseptic details as other surgical procedures, we could confidently expect non-febrile convalescence. The fact that sterilisation of the external genitals, the thighs, and the lower portion of the abdomen is sufficient, deserves mention. An ante-par-

tum douche is not only unnecessary, but is actually harmful, as has been shown by LEOPOLD and others. The use of gloves has not been satisfactory.

Third.—The use of anesthetics should be more general in private practice. Ether possesses many advantages over chloroform, and should be used, as a rule, when the pains are of moderate intensity. We have not had enough experience with the new method of spinal anesthesia to justify its use in more than an experimental way; and if added experience should show freedom from complications, we shall have at our command a method that is nearly ideal.

Fourth.—In the hands of the general practitioner a low forceps operation should be performed with greater frequency. It is easy of execution, is devoid of danger, saves unnecessary suffering on the part of the patient, and often actually enables us to preserve the perineal floor intact. On the other hand, however, median operations within the cervical canal and high operations should be done only for some special indication.

Fifth.—Non-febrile convalescence and freedom from local discomfort in cases in which the parturient canal is intact; it is of the greatest importance in the management of normal cases to acquire skill in so guiding the passage of the head and shoulders over the perineum that the risk of even a slight laceration may be reduced to a minimum. In addition to the danger of a mild puerperal fever, lacerations have a tendency to interfere with the involution of the vagina and uterus, and they predispose to many conditions requiring treatment by a gynecologist.

Too many obstetricians are careless in this respect, relying upon the usual good results of an immediate repair.

ON THE METHODS OF MAKING ANTITOXIC AND PREVENTIVE FLUIDS, WITH SPECIAL REFERENCE TO THOSE OF PLAGUE.

By C. BALFOUR STEWART, M.A., M.B., CANTAB.,
Thompson-Yates Laboratories, University College,
Liverpool.

It is unnecessary here to enter upon a discussion of the nature of immunity or of the action which takes place between toxin and antitoxin—a subject which we know very little about; but we may with advantage consider the means by which the human or animal body may be rendered immune to an infectious disease. It has long been known that immunity is in general obtained to the virulent disease by passing through a modified form.

IMMUNITY PRODUCED BY THE ATTENUATED VIRUS (LIVING MICROBES).

The first experiments in this direction with artificial cultures were made in 1880 by PASTEUR, who showed that immunity may be induced by inoculation with the attenuated virus—that is, with cultures of attenuated, but living, microbes. The outcome of these experiments was the protection of animals from anthrax and protective inoculation against rabies, although in this disease the specific micro-organism has not yet been found. In 1884

FERRAN first protected guinea-pigs against cholera by the same means; and later HAFKINE, in 1893-94, started protective inoculations against cholera in man on a large scale in India.

IMMUNITY PRODUCED BY MICROBES KILLED BY HEAT.

The method of inoculating with living microbes has its obvious disadvantages when carried out with the cause of a disease which may take a septicæmic form; and this fact led HAFKINE, when he came to experiment with plague, to try to immunise animals by inoculating them with microbes killed by heat. HAFKINE had observed with respect to cholera, and others before with respect to several other diseases, that it was possible to confer immunity by inoculating animals with the dead bodies of the microbes of certain diseases. An animal inoculated with either the attenuated living or with the dead microbe undergoes a reaction lasting several days.

The tissue cells of the animals, stimulated by the specific substance contained in the body of the microbe, are induced to elaborate an antitoxin or immunising substance; and the animal acquires an active immunity. An animal that has been at the trouble of manufacturing its own antitoxin has a more lasting and efficient protection than one that has been injected with an antitoxic serum obtained second hand, as it were, from an immunised animal. The antitoxic serum confers immunity almost directly, but its effects are fleeting—a fact which one would expect, considering the serum is a foreign body and is soon got rid of.

THE ACTIVE BODIES IN HAFKINE'S PROPHYLACTIC FLUID.

With respect to plague prophylactics, it is the intracellular poisons of the dead microbes that are mostly concerned in conferring protection, but HAFKINE injects the broth in which they have grown as well. He was led to adopt this measure from previous observation on cholera. The object is to counteract an attack of plague in an inoculated person—supposing he became infected—by previously accustoming the tissues to the poison given out by the microbe in the cultivation medium.

This theory assumes that the intracellular poisons induce a bactericidal power in the tissues, and that the extracellular poisons induce antitoxic properties which would come into play, supposing the bactericidal power were insufficient to prevent infection, that is to say, if the person did contract plague.

I showed by experiments on rabbits that the broth in which the microbes had grown apart from the bodies of the microbes was of use as a means of causing protection.

I have touched upon these points, because it has often been asked why the broth is used at all, and not the dead microbes alone, which would make the technique of manufacture simpler.

Since a dead culture only is used, the prophylactic is in no sense a serum. The false use of the word serum for what is really a vaccine is to be deprecated, for it gives a wrong notion of what the fluid really is. The word serum is constantly used in describing the prophylactic, even in Government reports. The very misleading,

not to say alarming, statement that inoculation with the prophylactic causes a mild attack of plague is not what one would expect from a scientific physician. A small definite quantity of plague poison is injected which is easily dealt with by the body and it cannot increase. There is the same distinction as would be between a case of mild septic intoxication and a case of septicæmia.

PREPARATION OF HAFKINE'S PROPHYLACTIC FLUID OR VACCINE.

The vaccine is a sterilised culture of the plague microbe in broth. The microbe should be obtained fresh from a case of plague, or from a culture in which the virulence has been kept up.

In India, where the religious prejudices of Hindu and Mohammedan have to be allowed for, the broth is made with goat's flesh in a way that is unnecessary to describe here. Ordinary broth as usually made in the laboratory is really better.

In order to ensure sufficient aëration of the microbe, which it would not obtain at the bottom of a flask of broth, HAFKINE first placed a few drops of oil or butter on the surface of the broth. The microbes attach themselves to the butter, and grow down into the broth in long threads like stalactites, forming a very characteristic and beautiful appearance. If the flask is moved, the "stalactites" break and fall to the bottom, to be succeeded by a fresh crop in a few days.

The stalactite formation not only serves its primary purpose, but is also a very important test in the bacteriological diagnosis of plague. The oil on the surface acts as a convenient substance for the microbes to attach themselves to. The microbe has a great affinity for any substance it can grow on; it prefers to grow up the side of a flask by continuity than to grow in the depths of the broth. Having attached themselves to the under surface of the particles of butter, they grow down into the broth. The microbe does not require a large supply of oxygen. I have grown it anaerobically and found it to be quite as virulent as a corresponding culture grown aerobically.

The flasks of broth are incubated at 70° to 80°F. At this temperature the microbe will have finished growing in about four or six weeks. This may be known by the fact that no fresh "stalactite" growth is obtained after shaking the flask and allowing it to remain stationary for a few days.

After the culture has done growing, its purity from contamination is tested by taking a small quantity out of the flask and inoculating an agar tube. If the agar is dry, and the culture spread evenly over the surface, the growth after one to two days' inoculation is seen as a thin, translucent, colourless film with a ground-glass appearance, when the underneath surface is viewed through the substance of the agar. Any stray colonies of a foreign microbe are easily seen. The broth culture which has been tested and found pure is then sterilised by heating it to 65°C. for one hour, and a small quantity (0.5 per cent.) of carbolic acid is added. The fluid is then drawn off into small bottles by means of a siphon.

ANTITOXIC SERUMS.

The antitoxic serum of YERSIN is used as a curative agent for plague. It also acts as a prophylactic agent, but the immunity conferred is very short—only about fifteen days. The principle of this serum is the same as that of antidiphtherial serum and others of like nature. An animal—preferably a horse—is immunised by inoculation at intervals with dead or living cultures of the specific microbe; after the first or second inoculation the quantities are increased and the intervals between shortened. The animal which takes the place of the human being who has been inoculated with a vaccine acquires an active immunity; and if the serum of such an immunised horse be inoculated in considerable quantities into a human being suffering from the specific disease, the disease is ameliorated or cured.

BACTERICIDAL AND ANTITOXIC ACTION OF SERUMS.

A serum may set in either of two ways: it may be bactericidal—that is to say, it can prevent the growth of the microbe in the body; or it may be antitoxic, in which case it exerts no bactericidal action, but neutralises the poisonous products given out by the microbe in growing, or it may be both bactericidal and antitoxic. The serum having bactericidal properties alone will suffice to prevent a disease if inoculated before infection; but if the serum be used as a curative agent, it must have antitoxic properties to counteract the poison already formed by the microbe, as well as bactericidal properties to arrest the growth.

With respect to anti-plague serum, ROUX asserts that the serums, however they are made, are always antitoxic, but the antitoxic property is more marked in some serums than in others; those made by injecting living cultures are more antitoxic than those made by injecting dead cultures. This fact, according to METCHNIKOFF, explains the difference in results obtained with YERSIN's serum.

PREPARATION OF YERSIN'S SERUM.

Having shown the possibility of preparing a curative serum in smaller animals, YERSIN, CALMETTE, and BORREL started to immunise a horse in 1895 at the Institute Pasteur. Living cultures of the plague bacillus obtained from Hong-Kong were used. Since injection of these cultures under the skin was found to cause long-standing induration, the method of intravenous injection was adopted, as much as a whole culture on an agar tube being used. The feverish reaction lasted for a week. After waiting twenty days, a second inoculation was made; the reaction in this case was intense, but of shorter duration. From this time larger quantities were injected at shorter intervals. The serum was found to be preventive and curative for laboratory animals after six weeks' treatment. It was from this horse after a year's treatment that the best results were obtained in Canton and Amoy in the summer of 1896.

YERSIN afterwards started making serum in his laboratory at Nha-Trang, using living cultures. ROUX started a stable of twenty-five horses at Garches near Paris, but he considered it inadvisable to use living cultures for so many horses, which could not be kept under observation in the laboratory. He therefore used cultures killed by

heat, and toxins formed in the cultivation media. The serums made both at Garches and at Nha-Trang were used by YERSIN in Bombay and Cutch Mandvi in 1897. The results were distinctly inferior to those obtained the year before at Canton. The results with the serum made at Garches with killed cultures gave the least good results.

On account of the inferior results of the Garches serum, and considering the progressive encroachment of plague, the Pasteur Institute decided to prepare several horses vaccinated first with cultures killed by heat and afterwards with living cultures, as was done in the first instance. This serum was used at Oporto in 1899, and gave somewhat better results.

VACCINE AND SERUM OF LUSTIG.

LUSTIG's method of preparing vaccine is based on the observation that a nucleo-proteid which he succeeded in separating from the bodies of plague microbes is a substance which induces immunising properties when injected; neither the metabolic products of growth nor toxins are used. The plague microbe is cultivated on agar plates and the growth is scraped off and dissolved in 1 per cent. sterilised solution of caustic potash. This solution is then rendered slightly acid with hydrochloric or acetic acid, and the resulting precipitate collected on filter paper; after washing it is dried *in vacuo*. This substance, which gives the chemical tests of a nucleo-proteid, is easily soluble in a weak solution of carbonate of soda.

LUSTIG proposes to use this solution as a prophylactic. He also immunises horses with it by repeated inoculations during a period of three or four months. The serum has been prepared in Bombay and tried at the Arthur Road Hospital.

So far, there has been no report of the use of the nucleo-proteid used as a prophylactic if it has been tried. The results of the curative serum were not at first very satisfactory, but lately better results seem to have been obtained. Dr. POLVERINI, in a report to the Bombay Municipal Committee, states that in 475 cases treated a recovery percentage of 39 was obtained. From the comparatively small number of trials of serum inoculation hitherto reported, neither serum seems to come up to what might be expected from a specific treatment. LUSTIG's serum does not appear to be so efficacious as that of YERSIN. This is possibly accounted for in a way similar to METCHNIKOFF's explanation of the difference in YERSIN's serums referred to above. A horse treated with a nucleo-proteid extracted from the dead microbes would be immunised with even less efficiency than one treated with the killed microbes together with their metabolic products, and a horse immunised in this way was shown to give a less powerful serum than one immunised with the living microbes. Compared in this way with HAFKINE's prophylactic, the latter is the greater success as a scientific preparation.

SURGICAL APPLIED ANATOMY OF THE RECTUM.

By THOS. CHAS. MARTIN, M.D.,

Lecturer on Diseases of the Rectum in the Cleveland College of Physicians and Surgeons, Member of the American Medical Association, etc., Cleveland, O.

ONE hundred cases of stricture of the rectum* reported by the ALLINGHAM'S are designated as situated at such a number of "inches from the anus" or such a number of

"inches up." For example: "Case number thirty-four, age thirty-seven years, female, constitutional syphilis, stricture one-half inch from the anus; case number thirty-six, age thirteen years, female, no constitutional disease, stricture about two inches up; case number forty-one, age twenty-seven years, female, no constitutional disease, stricture annular, three inches up; case number fifty, age thirty years, female, constitutional syphilis, stricture high up; case number sixty, age forty-seven years, no constitutional disease, stricture only to be felt."

Mensural methods of designating the situation of strictures in the rectum are of no surgical value. In the same subject the length of the fixed rectum is variable with a state of activity or passivity, and in a state of activity there are variations in its length of at least one inch (2.54 centimeters) between a contracted uplifted pelvic floor, and that of a depressed floor with anal eversion, both of which conditions may rapidly follow one upon the other, while the examiner's finger is engaged in diagnosis. Again, variations in depth of the fixed rectum are quite noticeably regulated by the size of the finger introduced. The thumb may find a fixed rectum of two inches (5.08 centimeters) in depth, while the little finger discovers it but a little more than an inch (2.54 centimeters).

The pelvic floor in the infant is about one-half inch (1.27 centimeters) in depth. The depth of the pelvic floor in the adult from the lower border of the relaxed external sphincter ani muscle to the levator ani muscle is extremely variable. In the aged male, because of senile enlargement of the prostate, the fixed rectum may be three inches (7.62 centimeters) in depth. In the aged female, because of senile atrophy of the generative organs and contiguous structures, the pelvic floor may be even less than an inch (2.54 centimeters) in depth. In the adipose and in the emaciated subjects, because of the character of the tissues occupying the ischio-rectal fossa, there are great variations in the depth of the pelvic floor; hence it is obvious that the palpable landmarks of the fixed rectum are situated at variable positions in the different sexes, and that the length of the fixed rectum is changed in the same person at different periods of life and in differing conditions of flesh.

The rectal valve constitutes the chief topographic feature of the moveable abdominal rectum. Its histologic character qualifies it the typical anatomic valve. The attached border of each valve spans a little more than half the circumference of the rectum, and its free border projects half across the diameter of the inflated rectum. Thus, what has been heretofore considered as a cavernous ampulla is seen to be divided into several chambers. There are as many chambers in the rectum as there are rectal valves. The number of rectal valves is variable. Some subjects have but two; others have four, but ninety per cent. of persons possess three. The uppermost valve is invariably situated at the juncture of the rectum and the sigmoid flexure, which valve is invariably situated on the left, the next lower is on the right wall, and the lowermost is on the left. The positions of the lower two valves are sometimes anterior and posterior. It must be readily seen that the new methods of rectal inflation for rectal inspection, which have determined our newer ideas of the topography of this part, justifies that the lowermost chamber be considered the first rectal chamber; the cavernous area beyond the first valve and below the second should be called the second chamber; and the upper chamber the third, and perhaps fourth, according to the number of valves. The ancient arbitrary division of the rectum by the anatomists into upper first, middle second and lower third parts should be abandoned. As the arrangement of the fibres of the muscular coats of the abdominal rectum and the attachments of the abdominal rectum provide for extension and contraction of the gut on its axis, as well as expansion of the diameter of the organ, it is obvious that there must be a great variation in the distance of any valve from the levator ani with the variable normal states of the organ. The normal

*Allingham, *Diseases of the Rectum*, page 261.

range of movement upward and downward of a given valve is from two to three inches (5.08 to 7.62 centimeters).

1. In treating lesions on a level with the sphincter muscles, the operator should never divide these structures through the anterior quadrant. In the male the external sphincter terminates in the tendinous raphe in common with the transversus perinei. Contraction of the transversus perinei will separate the divided fibres of the external sphincter, and defeat the desired subsequent union of this muscle. If an incision be carried forward, or forward and laterally into the transversus perinei, the perineal fascia, which doubles over this muscle, will be opened, and the perineum and peri-urethral structures will be made accessible to extension of suppuration, or other disease of the anus and ischio-rectal tissues. In the female an incision carried forward through the anterior quadrant would be unsurgical, because the peculiar arrangement of the fibres of the external sphincter ani and sphincter vagina, and their relation with the transversus perinei would perhaps conspire to produce vulvo-anal or recto-vaginal fistula.

2. A stricture located at the upper end of the fixed rectum and situated in the layer of the anal fascia, in the pelvic fascia, or in the fibres of the levator ani muscle, should not be cut in the anterior quadrant, nor in the posterior quadrant, but in one or the other or both lateral quadrants. An incision through the anterior quadrant on the plane of the levator ani muscle would divide none of its fibres, because there are none there, and would endanger the urinary organs, and the vagina in the male and female respectively. An incision made into the posterior quadrant on this level would fail to increase the diameter of the rectum, for the reason that contraction of the fibres of the levator ani would hold in coaptation the lips of the wound in such a manner as to early re-establish the stricture. A skilfully made incision in the lateral quadrants in this region will not endanger the peritoneum. A possible hemorrhage will be readily controlled; and because of the direction of the fibres of the muscle, a short lateral incision will effectually increase the diameter of the part.

3. The rectal valve must be reckoned with in studying the structures of the moveable abdominal rectum. Linear posterior proctotomy, because of the relation of the peritoneum to the posterior wall of the lower part of the moveable rectum, is made eminently safe, and will be efficacious in some instances. Semilunar (annular) strictures located at any other point of the circumference of the moveable rectum, and which are built on the foundations supplied by the rectal valves, may be safely cut through to the depth of a quarter of an inch (0.63 centimeter), provided the surgeon be equipped with the proper instruments, and provided the rectum be maintained in a state of atmospheric inflation at the time of the operation.

The writer's studies of the topography of the human rectum employed more than fifty autopsies on subjects of all ages, and physical examinations of several hundred living persons, and the facts which are set forth above justify the inference, he believes, that none but the topographic designation of the precise situation of the rectal lesion is of reliable surgical significance.

A MIRROR OF PRACTICE.

A CASE OF SUDDEN DEATH IN LABOR.*

By W. P. C. HAZEN, M.D.,
Washington, D. C.

SOME time prior to August 1898, I was engaged to attend Mrs. P. in her confinement, which it was expected would occur about the middle of August.

Mrs. P. was 28 years of age, and the mother of one child aged six years, at whose birth I had assisted. The patient was a strong, healthy woman, seldom having need of the services of a physician, and led a life of ease and comfort.

Shortly after having been engaged, I called upon the patient and found her in a perfectly normal condition, with the exception of some slight oedema of the ankles and legs. From this I was led to make an examination of the urine for albumin, but after three examinations at different intervals, I found only a slight trace of albumin present each time—not enough to indicate any kidney complication. Shortly after 8 P.M., on August 7th, I was summoned to attend the patient, who had been in labor since 8 o'clock P.M. Upon arrival at the house I found the patient in a very cheerful and hopeful frame of mind, and discovered upon examination that the os was slightly dilated, and that at irregular intervals she experienced the usual short, cutting pains. I made out a normal head presentation. I remained at the house about one hour, in order to observe the rate of progress, and found that everything was progressing in a perfectly normal manner. I informed the husband of the favorable conditions, and that I would return in two hours, unless called sooner. About 11:30 P.M. the husband came for me, stating that his wife was having very severe pains. Upon my arrival at the house, I found the patient again in the same calm and apparently normal condition, and upon examination found the os well dilated, and that the bag of waters had ruptured and labor appeared to be progressing normally.

After being in the room a few minutes, I noticed that the patient was annoyed somewhat by a slight, dry cough, which appeared to be of nervous origin. This cough gradually increased in frequency and severity during the remainder of the labor.

About 1 o'clock A.M. I found that the head was resting upon the perineum, and advised her to agree to the application of the forceps, in order to relieve her of any further suffering. She consulted her husband, who readily agreed, and then she concluded she would prefer to "let nature take her course." A few minutes later she was seized with a severe spasm of coughing. She sat up in bed and expectorated a small amount of frothy mucous, tinged with blood; and turning to me she said in a calm, mild manner, "Doctor, I believe that I am dying;" and before I could reach her side to support her, and in less time than it takes me to tell it, she fell back on her pillow, dead. The child was delivered dead.

The family were opposed to *post-mortem*, and I am free to confess that to the present moment I am ignorant of the exact cause of this fatal termination of what was in every other respect a typical normal labor.

*Read at a meeting of the Medical and Surgical Society of the District of Columbia, December 1, 1898.

I have since elicited the fact from relatives that the patient, when a young girl, suffered from an attack of inflammatory rheumatism. But, during the whole period of my acquaintance with her—a period of at least seven years—she had been a perfectly healthy woman in every respect.

In looking over the literature on the subject of "sudden death in labor," and the cause thereof, I could not help being impressed with the poverty of medical literature upon this subject. True it is that there have been many interesting papers upon the subject, and by eminent and able authors, but they consist almost entirely of detailed and graphic accounts of particular cases, and, with but few exceptions, no very satisfactory explanations as to the causes of such a tragic ending of what should be one of the happiest events in domestic life. Professor Lusk himself acknowledges: "But when the conscientious physician seeks for light concerning the cause of the tragedy in which he has played the part of a powerless spectator, he will find but scanty guidance in the few brief lines devoted to the subject in the systematic treatises upon midwifery."

In an attempt at a classification of causes of sudden death during labor, HIRST, in his work on Obstetrics, gives the following eight causes:—

- 1st. Mental emotion.
- 2nd. Severe suffering and nerve exhaustion.
- 3rd. Disease of the heart.
- 4th. Rupture of the aorta or other internal organs.
- 5th. One of the accidents or complications of labor.
- 6th. Pulmonary thrombosis or embolism.
- 7th. Entrance of air into the uterine veins.
- 7th. Disease of the respiratory organs.

DISCUSSION.

Dr. BOVEN has never seen but one case of such an accident, but had seen references to it. He cannot account for it, except by supposing there was some heart trouble from rheumatism or muscular or nerve strain. Is astonished at the small number of cases reported, since there is great muscular strain and nervous excitement at the time of labor. Some authors insist upon there being a compensatory hypertrophy of the heart during pregnancy, so that it may be prepared for the extra tax to be placed upon it at labor. Thought œdema of the lungs may have been present, but not noticed, as suggested to me by Dr. SOTHORON. This, from fatigued circulation, may occur rapidly, and even escape notice, because of the environments. This was probably the cause of death in Dr. HAZEN's case.

Dr. SOTHORON asked whether there was cough and how long it had lasted; also if internal hæmorrhage had occurred.

Dr. HAZEN said there was a slight cough, but no internal hæmorrhage.

Dr. BOVEN said there were other causes of death, and suggested rupture of the uterus, with escape of the fetus into the abdominal cavity. The shock accompanying such an accident had caused instant death in a patient in his hospital service.

Dr. STONE said it was hard to give the cause of death in this case, in view of the fact that a *post-mortem* examination had not been allowed. The cough had been present, there may have been œdema of the lungs, pleuritic effusion or cardiac disease. Heart disease may have been present, but not diagnosed; sudden death is often due to heart disease which may have existed for years.

Dr. SOTHORON questioned whether œdema of the lungs could cause so sudden a death as had occurred in this case.

Dr. STONE related a case of sudden death in an apparently healthy man, who had been kicked by a horse in the region of the heart—death followed from œdema of the lungs.

Dr. BORDEN, in speaking of the causes of sudden death related a case of an enlisted man, who died suddenly on leaving the dining table; *post-mortem* failed to show lesions. There had been no shock, no history of alcoholism, nor had he ever been sick. In another case a hospital steward, who had been exposed to cold, although his condition was good, died fifteen minutes after observation. In this case the *post-mortem* showed œdema of the lungs; other organs healthy.

Dr. VINCENT related cases which he had seen in hospital; one of simple bronchial inflammation, another of pneumonia.

Dr. HAZEN, in closing, said the woman was apparently healthy, weighed about 130 pounds, was 5 feet 6 inches in height. Her first labor had been terminated with forceps; was not seen in the interval. The heart had not been examined, since there had been no occasion to do so; urine was normal in quantity and composition. Her cough, towards the last, was aggravated; there was no evidence of internal hæmorrhage. He had certified the case as one of œdema of the lungs. Had seen one death from rupture of the uterus, but it occurred slower than in this case. No medicine of any kind had been given.

SARCOMA TESTIS.

By C. PAPAROW,
Medical Student.

WHEN I was attending the Vizagapatam civil hospital during the summer recess with the permission of District Surgeon Lieutenant-Colonel A. H. LEAPINGWELL, the midwife attached to the Baptist Medical Mission of Chicacole (Ganjam District) came to the hospital under the orders of the lady doctor of the mission with a pariah woman and her son, APPALASAMI, aged two years and three months. The mother looked very healthy, and did not show any signs of suffering. The boy looked flabby rather than healthy to all appearances, but had been suffering from one afflicting complaint. It was really an afflicting one, for it gave him an excruciating pain on movement. The pain was located in his right scrotum. The first class Hospital Assistant attached to the hospital examined the boy, but was not certain of his diagnosis, and so he reserved it to himself. The mother and the child were admitted into the hospital as in-patients on the 27th April 1900. On the next day the District Surgeon examined the boy, but he, too, did

not come to any settled diagnosis, for the case looked to all appearances to be one of hæmatocele, but the scrotum was glistening and blackish red. It was very hard to touch, and turned more towards the middle of the right thigh than towards the left. It was found on examination neither to be a case of hernia, nor a case of hydrocele. The doctor was bent on exploring it. He did explore it at last, but failed to find out any signs of hæmatocele. Then he thought that it might be either a case of "sarcoma testis" or "elephantiasis scrotum," and on close examination the former proved to be right.

The child, APPALASAMI by name, is the only son of a pariah cultivator in an adjoining village near Chicacole. The parents of the boy are very healthy and vigorous, but the boy himself, as has already been remarked, looked flabby and anæmic, and bore signs of agony every now and then, owing to the severe pain in his scrotum. The pain was aggravated on movement, so he had to lie down flat either on his mother's lap or on the bare ground. On enquiry, his mother told me the following history of her son. Some ten months ago, it seems he had had a fall from the pial of her cottage against a stone in the street; thereby he received a blow on his right testicle, which accordingly showed some of the primary signs of inflammation which gradually subsided within a fortnight. Practically the boy did not suffer at all for a time after the incident, but pain in the right testicle did not disappear entirely, so he became subject to that pain, which gradually increased. She tried all her best with the few medicinal resources with which the Hindu mothers treat all minor complaints. They use some indigenous drugs which are represented by some native doctors to be very efficacious, but are really not so. Unhappily, but not unnaturally, these drugs had no effect on the boy's malady and agony, which were only aggravated by her injudicious modes of self-treatment. She had even gone to the length of branding the boy on both sides of the inguinal and femoral regions (more on the right). Not being satisfied with this, she paid homage to many a devatas shrine, giving all sorts of animal sacrifices which are believed by the low caste Hindus to relieve them of their affliction and anxiety and restore them to health. She tried all these, and many more crude methods, and tried them only in vain. At last, wisely or unwisely, she went to Chicacole to try her chance with the lady doctor of the Baptist Mission. The lady thought it fit to send this case for treatment to our talented surgeon. Accordingly the mother and the child came to Vizagapatam accompanied by the midwife of the mission. They were admitted into the hospital, and on the second day Dr. A. H. LEAPINGWELL explored the case, and found it to be a case of "sarcoma testis." The scrotum was very opaque and darkish red, and its size and weight were too troublesome for the boy to carry. The boy was put under chloroform and was operated on. The doctor thought it best to remove the whole of the right testicle with its sarcomatous growth; so he removed it entire with the cord and its appendages. The left testicle was very healthy, and ran high up to the external ring, and stood there safely without being caught by the sarcoma-

tous growth of its fellow; so he did not meddle with it, and sutured the scrotum, carefully inserting a small drainage tube into it. He dressed it with the necessary antiseptic precautions and with the usual "B. and I." dressings. Successful operations with antiseptic precautions, which owe their origin and growth to the venerable Lord LISTER, mark an epoch in the history of operative surgery in the end of the nineteenth century. The results of the above treatment are as follow: On the sixth day after operation the drainage tube was removed. Within a fortnight the boy looked cheerful and gay, so the boy and his mother were discharged from the hospital on the 13th May 1900.

The scrotum was so big and pendulous that it extended even to the distal end of the middle third of the right thigh. The integument and all the coverings around the right testicle were very hard to touch and pale on section; but between the two layers of the tunica vaginalis we observed a sort of brownish growth showing faint signs of ulceration. After the removal of the right testicle, I separated it from its sarcomatous growth and preserved it in spirit, making it into two. It resembled to some extent on section an enchondroma, but I think it might be a chondrifying sarcoma. Anyhow, it is surprising to see a case like this making its way into a sarcomatous growth from a mere hit against a stone. The boy left the hospital with one testicle, but he was saved by the able doctor from the peril of dragging his life to a miserable end. The boy looked very curious to me before operation, as he had a scrotum of the size of an average cocoanut. He also astonished the talented and popular surgeon, Dr. A. H. LEAPINGWELL, who, by the way, remarked that he had not come across such a case during his vast and varied experience of more than a quarter of a century. This remark of my revered doctor, under whom I had the pleasure of serving during my pre-collegiate course, prompted me to preserve it for an opportunity like this.

CASE OF URINARY CALCULI LODGED IN THE VAGINA; AND A CASE OF SUPRAPUBIC LITHOTOMY FOR A LARGE STONE.

REPORTED BY H. F. LECHMERE TAYLOR, M.B., C.M., EDIN.,
Surgeon to the Mission Hospital, Jalalpur, Jattan, Punjab.

THE patient, a Hindu girl, apparently aged about 15 years, was brought to the hospital on February 2nd, 1890, in a semi-conscious condition and an extreme stage of emaciation. The parents, who were very dull mentally, stated that a stone had been removed four years before, but could give no information as to the operation. The patient was suffering from diarrhoea and incontinence of urine, and there was a foul greenish mucous discharge from her vagina. On passing the sound, a stone was felt within

half an inch of the meatus; an attempt to grasp it with dressing forceps was unsuccessful. On passing the finger into the vagina, a stone the size of a walnut was encountered. The vulva was slightly incised in the middle line posteriorly, and the stone removed with lithotomy forceps. Behind it were found four others packed into the fornices of the vagina, which were widely distended, the whole canal being tubular, with the os palpable as a dimple in the roof. The patient appeared to be moribund, but gradually rallied after a hypodermic injection containing 5 minims of the liquor strychninae. Owing to her general state, no further attempt was made to explore the local condition. During the next eighteen hours two enemata were given containing an egg beaten up in milk, with boryl and some alcohol. Next morning she began to take food by the mouth. The stones were rounded in shape, faceted, evidently largely composed of lime salts, and weighed altogether 2 ozs. 100 grs. A superficial sloughy ulceration set in, which was treated by frequent antiseptic syringing and dusting with iodoform and boric acid. On the sixth morning, on removing a slough, another stone was revealed. Chloroform was given, the stone removed, and a thorough examination made. The septum between the vagina and urethra was absent except at the meatus, where a ring about $\frac{1}{4}$ inch broad remained. Between the neck of the bladder and the os cervicis was found an irregular circular opening with thickened edges—a vesico-vaginal fistula, which admitted the index finger. The bladder was empty. The sixth stone weighed 1 ounce 45 grs. The patient made no headway, and on February 10th a dome-shaped slough, about the size of half a goose's egg, was removed from the vagina. She died early on the morning of February 12th.

In the second patient, a man aged 20, a large stone could be felt *per rectum*. The operation was uneventful, but the wound had to be repeatedly enlarged, the muscles also requiring division transversely. Considerable force was used in the removal of the stone, which weighed 8 ozs. 2 drs. and some grains. No attempt was made to sew up the bladder. Considerable sloughing took place, and once secondary hemorrhage threatened to be serious. The wound opened into a cavity through which the interior of the bladder could be seen. A red rubber catheter was kept in (its end having been cut off from above and several perforations cut in its sides) to ensure good drainage. The patient gradually sank, and died on the thirtieth day after the operation.

Nature Treatment of Tuberculosis.

R. O. BEARD says that the study of the warfare waged between the human tissue cells and the bacillus tuberculosis teaches us the lesson that the task of the public sanitarian and the physician is largely one of prevention, and that cure—a secondary and short-lived possibility in the course of the disease—is best accomplished by extending the principles and methods of prevention to the assistance of the tissue cells. Only now are we learning that but two prime factors are essential to make localities favorable to the tuberculous patient—purity and dryness of atmosphere, in whatever latitude, at whatever altitude, on plain or mountain, in forest or on ranch. Consumptives should be isolated. Tuberculosis should be quarantined in our towns as effectively as yellow jack. As to the creation of the Minnesota park, the nature treatment of tuberculosis in this available region will repay the nation in men more than it can gain in timber by its destruction or in navigation by its saving. As nearly complete physiological rest as possible should be attained by the consumptive. Forced feeding is also an important element in treatment. The gradual increase of food is well endured even in advanced cases. The combination of all these measures should brighten the hope of control of this most destructive of the diseases of civilization.—*Med. News.*

Indian Medical Record.

16th January 1901.

BOGUS AMERICAN M. DS.

GANGADIN VERSUS THE "INDIAN MEDICAL RECORD."

OUR readers will be interested in scanning through another phase of the recent defamation case at Lahore. Whether by wilful design or not, failing to put in an appearance at the trial which he instituted in Lahore against the *Indian Medical Record*, GANGADIN now has the impudence to endeavor to pose as a martyr to judicial hard-heartedness. It looks very much like another wily ruse to sustain a deliberate hoax, for GANGADIN now knows, if he was so stupid and dull-headed as not to know before, that his so-called "diploma" are out-and-out frauds. To give point to our remarks, we publish GANGADIN's letter to the leading English paper of the Punjab, and our reply thereto:—

"AMERICAN MEDICAL DEGREES.

TO THE EDITOR, "CIVIL AND MILITARY GAZETTE."

Sir,—I have read your article entitled "American Medical Degrees—Action for Defamation in Lahore," published in your issue of 5th December, and I think I must say something in order to efface the impression which your article might have produced upon the mind of your readers. First of all I must say that I am astonished to see at your taking such a hasty step in giving publication about a case which is not yet finished. I now inform you and the readers of your paper that I was really ill and so could not attend the Court on 3rd December, hoping that the City Magistrate would be also kind enough to me by granting an adjournment of a few days, as he had done in the case of the accused (Dr. WALLACE) by granting him four months' adjournment when his Counsel had asked for it; secondly, I was under the impression that as he had been kind enough on the accused by allowing him always to appear by pleader, he would at least excuse my one day's absence from the Court when I was ill and when my Counsel was present; but I simply regret that he had not been so kind in my case. However, I have no right to compel Mr. STOW (City Magistrate) to show me the same kindness what he showed to Dr. WALLACE the accused.

Now as regards the order of the City Magistrate acquitting the accused under Section 247, C. P. C., owing to my absence from the Court, I am informed by my legal adviser that it is utterly unjust and illegal, and so I am going to get his order of acquittal set aside by moving some higher authority. Section 247, C. P. C., applies to summons cases, and not to warrant cases. The charge brought against Dr. WALLACE was under Sections 501 and 502 of the I. P. C., which are warrant cases, and are classed so under Schedule VII of C. P. C. The City Magistrate could have discharged the accused under Section 259 of C. P. C., and not acquitted him, as he has done. Any

one suspecting my abovesaid statement can look into the Code of Criminal Procedure, and he will at once be satisfied. The next thing to which I wish to draw the attention of the public is that all the Diplomas which I hold are genuine, got by regular study and passing examination, from respectable institutions. Any one wishing to look into my diplomas is welcome to call at mine, and see for himself.

I am sure that the City Magistrate himself is satisfied that my Diplomas are genuine, although he has acquitted the accused on account of my absence from the Court on 3rd December, as he, when he took my statement on the day when my complaint was admitted, asked me that why did I not accept an apology from Dr. WALLACE, and my answer to this he has recorded in the proceedings. This was probably the last question that he asked me after thoroughly examining my Diplomas, Governmental papers of America, and such other important papers showing conclusively that I was in America and had studied there.

Thirdly, I wish to inform you and the readers of your paper that although it is considered an unprofessional conduct for medical men in England to advertise, it is not considered so in India. There are dozens of old qualified medical men who advertise, and in order to substantiate this, I give a few examples. [Here follow three names and dates and journals in which advertisements are said to have appeared.] Among the Assistant Surgeons there are a host who advertise. [Here follows list of names, dates and journals.]

In fact it is custom among the junior practitioners, at least, to advertise, and is not considered in any way bad either by the Indian public or by the majority of Indian medical practitioners.

Medico of Hyderabad and Lahore Surgeon, who defamed me in the *Indian Medical Record* should have boldly given out their names, it is a pity that they did not; and they are still keeping me and the public in dark.

GUNGADIN, B.Sc., M.D.,

Late of Lahore.

KARMON-KI-DEORI;

Amritsar, December 12th, 1900.

(Published in *Civil and Military Gazette* of 16th December 1900, and reproduced in the very identical scholarly English (?) in which it appeared.—Ed., *I.M.R.*)

"AMERICAN MEDICAL DEGREES.

GUNGADIN *versus* THE "INDIAN MEDICAL RECORD."

TO THE EDITOR, "CIVIL AND MILITARY GAZETTE."

Sir,—My lawyer in Lahore in the above case has sent me, through my lawyers in Calcutta, a copy of a letter addressed to the *Civil and Military Gazette*, which appeared in that journal recently, from a man named GUNGADIN, the plaintiff in the above case. As the case was dismissed, and the Editor of the *Indian Medical Record* was acquitted of the charge of defaming GUNGADIN, the latter, who did not appear in Court to undergo cross-examination, now appears in public, through your journal, to refute the statements of the *Indian Medical Record* regarding the lack of genuineness and the legality of his so-called degrees. Under the circumstances, I feel it my duty to the public to reply to GUNGADIN's letter.

He states :—(1) His diplomas are genuine; (2) that he was in America and studied there; (3) that his diplomas are "Government papers of America;" (4) that medical advertising in India is not unprofessional.

1. Are GUNGADIN's diplomas genuine? What are they?

In his sworn affidavit before the City Magistrate of Lahore he said he was M.D. of the Medical College of Indiana, B. Sc. (Bachelor of Science) of the Chicago College of Science, and Fellow of the Indiana Academy of Medicine. He swore that he studied Medicine in America, and that he was educated in the Calcutta Homeopathic Medical School.

I have written to the responsible authorities in Indiana and Chicago. Their replies were in the hands of my counsel, and this evidence would have been before the public had GUNGADIN continued to display the same zeal in the prosecution of his charge, as he did in the laying of it.

Having deprived the public of my evidence by his non-appearance in Court, he now seeks to support his claim to being considered a duly qualified medical man by making the statements in his letter to your journal which I have quoted.

Here is some of my evidence :—

(a) From the Secretary to the State Board of Health of Illinois, (Dr. J. A. EGAN):—"I have before me the Annual Announcement of the Medical College of Indiana, Indianapolis, for 1900-1901, in which there is published a list of the alumni of the institution up to and including the year 1900, but after careful search, I fail to find any graduate named GUNGADIN, or any name similar thereto. It is probable, therefore, that the diploma referred to is spurious. I would suggest that, if possible, you have this diploma examined, getting the correct name and date of issuance, and advise me, whereupon I can give you definite information. The Chicago College of Science, extinct 1889, was, during its brief existence of one year, a fraudulent institution. It had been repeatedly exposed by this Board."

(b) From the Secretary of the State Board of Health of Indiana, (Dr. J. N. HURRY):—"We are requested by Dr. J. EGAN, Secretary of the State Board of Health of Illinois, to give you information concerning the 'Indiana Academy of Medicine.' There is no such institution or association in Indiana. There may have been in the past, some quack or false combination under this name, but it does not now exist. All diplomas or certificates which may have been issued by the Indiana Academy of Medicine are without standing, and are unrecognised by the Indiana State Medical Societies."

(c) From the Secretary of the State Board of Health of Indiana (Dr. J. N. HURRY):—"The Medical College of Indiana is a reputable institution, and its diplomas are recognised in every State of the Union. In reply to our note to the Medical College of Indiana, we are told that no such name as GUNGADIN, or one like it, is upon their records. Neither is any one of such name, on the State records of Indiana, as a licensed practitioner."

(2) I have further evidence to prove that GUNGADIN underwent no orthodox course of medical study in any reputable college in America. I can prove by documentary evidence that he was admitted into a bogus institution in Calcutta, called the Homeopathic Medical School, without any passport of a preliminary English education, and that he attended a few of its "lectures."

(3) GUNGADIN endeavours to delude ignorant and unsuspecting readers of your journal into the belief that the "papers" he displays as "diplomas," are "Government papers of America." I have clearly proved that the authorities—the authorised agents of the American Government—declare the B. Sc. of the Chicago College of Science to be "fraudulent," and the Fellowship of the Indiana Academy of Medicine to be another "fraud," and it is further clearly proved that GUNGADIN is not recognised or known as a graduate in the degree of M. D. of the Medical College of Indiana.

I trust that your readers will admit that in repudiating GUNGADIN's claims to membership in the profession of Medicine I have simply done my duty to the public, for I have the constant assurance in my own mind that those who personally know me will readily and frankly acquit me of the faintest shade of malice against a man whom I do not know, except by name, and by his unenviable reputation of advertising his "professional" (?) virtues in the lay papers and by other means.

(4) I have heard it said that poachers do not look upon poaching as a crime, nor even as an offence; so, possibly upon this line of argument, there may be men in the medical profession who, being "advertisers," do not regard "medical advertising" as an ethical offence. However, GUNGADIN will find not only public opinion against him in this matter, but Indian law-courts also, for the ethical code of Medicine not only regards advertising as unprofessional, but its representative bodies are possessed of the penal power of depriving medical men, guilty of such misdemeanor, of their diplomas, and turning them out of a profession which they degrade and dishonour by such conduct.

Yours, etc.,

JAMES R. WALLACE,

Editor, "Indian Medical Record."

Calcutta, 23rd December 1900.

(Published in the *Civil and Military Gazette* of 1st January 1901.)

We feel sure our readers will be satisfied that GUNGADIN has no claim to being considered a member of the medical profession, and that the falsity and barefaced audacity of his pretensions have received a well-merited quietus.

HOSPITALS: SOME ASPECTS OF THEIR CONSTRUCTION AND EQUIPMENT.

THE *Journal of the American Medical Association* publishes a valuable and interesting article on the construction, organization and management of hospitals, by Dr. J. R. McDILL, M.D., Major and Brigade Surgeon, U. S. V. Commanding Hospital. We give the essentials. After a somewhat lengthy historical review of the progress and improvement in these institutions prior to the sixteenth century, the first important subject touched upon by the author was the development of the study of ventilation by CARDINAL DE POLIGNAC in 1703, and by DRAGUINAS in 1727. Positive science had been established only at the beginning of the eighteenth century, and the

practical adaptation of science and inventions then only just began, and curative medicines was hardly in advance of the times of HIPPOCRATES. STENENHAM had done much in the latter part of that century to influence advances in medical science and earlier, HOFFMANN, BEUCERS and ARBUTHNOT. The great movement in hospital-building took place in the eighteenth century, and several institutions were then established. The most useful hospitals were, and had been, general ones, built upon the pavilion plan, with ample acreage, with wise management, principally under medical officers' control, under whose roofs every medical man was a free, independent and responsible agent, enjoying equal rights with all, as far as consistent with wise general management. The mortality in these old pavilioned hospitals had been pretty generally in the ratio of the size of the hospital, and the consequent aggregation of patients, the crowding together in the wards, the deficiency of ventilation, defective sewerage arrangements and want of constant attention to the details of cleanliness. The broad general object for which hospitals were established might be stated to be the gratuitous medical and surgical treatment of the indigent sick. Many abuses had, however, crept in, and large numbers yearly received medical treatment gratuitously, who were quite able to pay for it. To obviate this, the establishment of paying institutions had been recommended. If this, however, could be accomplished, it should be done with fairness to all concerned, and with as little harm as possible, especially in the direction of promoting negligence, shiftlessness, laziness and vice—the pauperising of the people. The writer did not enter into the question of special hospitals, such as hospitals for military purposes, for consumption, for incurables, etc., as being too vast a subject. In referring to hospitals for infectious diseases, it was pointed out that the fulfilment of the duty of providing suitable accommodation therefor was a task apparently very little to the taste of sanitary authorities. As a consequence the provision for such hospital accommodation got shelved from time to time, until an epidemic occurred, when a frantic effort was made to put up a temporary hospital in a few days to cope with the urgency of the moment. A permanent "isolation" institution was wanted in every city and town, to provide the means of isolating at once the earliest cases of disease, and of thus preventing the epidemic, instead of leaving it to be battled with when it had got full away. For this purpose the author considered STROHMAYER's canvas barrack hospital, kept on hand by State or Municipal authorities, to be the most suitable. The most perfect permanent isolating ward, however, was in the Johns Hopkins Hospital. The writer then referred to the considerations in planning and making specifications for a scientific hospital. Thoroughly fireproof construction was not necessary: the semi-fireproof or slow burning construction was sufficient. As regards the site, the following points had to be considered: (1) Aspect and conformation of ground: high water level and prevention of an upward current of the soil air into the building. (2) Nature of soil: refuse of all kinds should be excluded and avoided. (3) Area in relation to number of beds. (4) Convenience of access for patients, physicians and students; and lastly, the cost. The foundations should have a

solid concrete base, with lines of drain tiles laid around them, preventing the moisture in the soil from being drawn up into the walls by capillary attraction. The walls of the building should keep out the air, and on the internal surface should be absolutely impervious, capable of being washed down and thoroughly cleansed without its impermeability being affected, and in such circumstances a larger supply of air would be necessary than would be the case with walls of ordinary construction. The floors of the wards, operating rooms, etc., should be a solid and fireproof surface of solid oak or teak, laid on a surface of cement or concrete and wax polished or paraffined. All angles between the floor and the wall should be rounded to a radius of not less than two inches, and no mouldings involving sunken recesses or grooves should be permitted, and all angles in which dirt can lodge should be abolished. The windows should consist of two sheets of thin glass with an air space between, perfectly airtight. Doors should be wide, 42 inches, without thresholds. The linen room should, above all things, be spacious, provided with abundant air, light and ventilation, and also artificial heat, and have washable walls. The floor space must be at least 100 square feet per bed, and the ceiling need not be more than 12 feet high, as the space above that height was of little value as ventilation space. In connection with the subject of ventilation, the question of keeping rooms warm arose. Warming consisted of the direct and indirect varieties, of which the indirect seemed preferable. Ventilation resolved itself into two systems: (1) Natural, *i.e.*, unaided by mechanical contrivances. (2) Artificial or forced ventilation. The natural system depended upon the ordinary means of windows, aided by smoke flues from grates &c. Artificial ventilation was arranged in two ways: (1) Either air was forced into the ward by steam fan power, or (2) vitiated air was drawn out by means of hot water coils in the exit shaft. In the writer's opinion the best ventilating and heating arrangement was JOHN HOKINS' system. This consisted of a double system of outlets—one in the floor and one in the ceiling—the object being that the floor outlets may be used in winter or cold weather for the purpose of economising heat, while in summer both sets might be fully opened. In the isolation wards perforated floors were employed for heating and ventilating, the air passing constantly upward, placing the patient, as it were, in the condition of being out of doors in a very gentle current of air. In reference to sewage disposal and house drainage, all soil and other pipes were so placed as to be readily accessible and freely exposed to view. Water-closets were to be disconnected from wards by intervening lobbies and be perfectly ventilated, and the mechanism for supplying water must be as simple in construction, as strong, and as nearly self-acting as possible. The whole of the contents of the flushing cistern should be capable of being discharged at one time. Basin and trap should be of the simplest form and entirely of white enamel, and the traps properly ventilated through the roof. In close proximity to the closets should be a separate space enclosed for the slopsink, with provision for keeping bedpans, brooms, &c., and here also should be a cupboard ventilated to the whole extent of its external or wall

side into the outer air, in which to keep faces, etc., required for examination by the medical staff. There was no necessity, however, as in the case of closets, of interposing a disconnecting lobby between a bath-room and a ward. Bath-tubs should be away from the walls and surrounded by moveable floor slates. The electric system of lighting was infinitely the purest and best, and the water-supply should always be well filtered. In connection with the operation house, the writer considered that there should be three separate rooms—one for a surgeon's dressing room, one for instruments and sterilisations, and one for preparation of patients—placed as far as possible from serial contact with wards or other parts of the hospital, of a size of 30 feet by 40 feet. Every detail in the operating room was to be devised with a special view to its aseptic necessities, everything of an absorbent nature being eliminated. A north window should furnish the principal light, and be formed of one sheet of plate glass 10 or 12 feet by 8 feet, fitted in a wrought-iron frame, flush with marble or glass and wall. Other windows should be constructed in a similar manner, but made to open for purposes of ventilation—every part should be impervious, readily cleaned and easily seen. The operating room should have two 100-candle power electric lights, with an arrangement allowing of any angle of reflection, and also two portable incandescent lamps with flexible connections. Operating table and floor should not be connected in any way with the general drainage system of the building, and a large constant supply of water sterilised and at a temperature of 130° should at all times be readily obtainable. The furniture should be "aseptic," made of white enamelled wrought-iron and glass. Of paramount necessity in all hospitals was a large general disinfecting apparatus of some kind, both for the purpose of destroying vermin in clothes, and for disinfecting bedding, etc., after cases of infectious diseases. The only trustworthy process was the application of steam under pressure at a boiling temperature or even greater. The germicidal property of steam depended upon its moisture and on the expulsion of air contained in the articles to be sterilised. An efficient apparatus should provide means for subjecting the articles to be disinfected to actual contact with an overhead streaming steam, which expels every particle of air from top to bottom, while the apparatus is getting heated; and then the removal of vapour by a new filling of the disinfector with air from below upward, before the steam can condense sufficiently to injure the articles disinfected. The large RZOK and the smaller BOECKMANN sterilisers were scientifically perfect and efficient. Disinfection by formaldehyde gas was the most recent method, and probably one of the most efficacious and economic known. The necropsy laboratories and museum departments should be together in a separate building and include a crematory. The kitchen, laundry, boiler and bath-house should also be in a building or buildings entirely separate from the hospital proper. A well-managed, though poorly constructed, hospital would, however, give a far better result than a finely constructed hospital with bad management. Badly constructed and managed hospitals would be built, and the causes of disease would continue to create preventible diseases just so long as doctors left these matters to business men, politicians and their architects, especially when the latter happened to be amateur ventilators and sanitarians. Such institutions were always liable to cause hospital diseases and become centres of infection, thus defeating the very object they were intended to promote.

DISCUSSIONS AND NEWS.

RENAL-TUBULAR PAIN.

In a paper read before the Canterbury Section of the New Zealand Branch of the British Medical Association, Dr. F. CLARKE FARWICK, M.B., M.D., L.R.C.P., Surgeon to Christ Church Hospital, New Zealand, spoke on the subject of genito-urinary pain. We extract from the *Australasian Medical Gazette*. After recalling with some minuteness to those present the nerve supply, both sympathetic and somatic, of the abdominal cavity, with special reference to the urinary organs, the speaker pointed out that the belief was justifiable that an abdominal organ may, under various conditions of disease, set up irritation in its sympathetic nerve supply, which could be conveyed to the spinal cord, and thence might be reflected to certain spinal nerves, and so find expression in that part of the body which is supplied by the particular spinal nerve receiving the reflected irritation. In regard to backache due to renal disease, the speaker distinguished two varieties: (1) The back seemed bruised, the pain being dull and throbbing, with no stiffness, no increase on movement or subsidence on rest. On pressure the pain was not appreciably increased. The patient was unable to rest in any posture, but in many cases found most ease in the prone position. The urine was always scanty, high coloured, acid, and small in quantity. The patients were all small drinkers and non-smokers, and the pain was obviously due to renal congestion. The only successful treatment was hot baths and free drinking, with a course of saline diuretics. (2) The pain was sharp, lancinating, increased on the least movement, causing stiffness; the muscles were tender on pressure, and great relief was given by complete rest. The urine was abundant, very light coloured, of very low specific gravity and extremely acid. There was frequent micturition due to the hyperacidity reacting on the vesical mucous membrane. The only successful remedy was liquor potassae in 15 minims doses till the urine became alkaline. The patients were, invariably young adults, who indulged freely in meat and drank strong tea. The pain due to renal calculus was distinguishable by its limitation to one side, and extension round to the front and down to the testicle or groin. From hyperacidity of the urine the speaker had known even violent asthma to follow, cured simply by rendering the urine alkaline. The explanation lay in the connections which existed between the renal plexus and the pneumogastric nerves. The retraction of the testicle in certain renal cases might be understood, by remembering the cremasteric nerve supply was derived from the genito-crural, and that the renal plexus was closely connected to the upper part of the lumbar plexus. The acute collapse and vomiting during the passage of a calculus found explanation in the relationship between the filaments which cover the ureter and are derived from the hypogastric plexus, which also supplied the coronary and diaphragmatic plexuses by its brotherhood to the solar plexus. Whilst the kidneys had their pain area at the upper lumbar region, the pelvic organs had theirs at the lower lumbar and upper sacral portion of the spine. The bladder was covered with a delicate network of a plexus derived from the hypogastric, but consisting in large part of fibres from the third and fourth sacral nerves, and thus an immediate connection was made between the sympathetic and somatic nerves. In bladder tetanus, as from tumour, the principal pain was referred to the fifth lumbar spine, whose pain in the prostate was also referred to. The speaker had noticed that a congested prostate with much pain

associated with haemorrhoids was almost pathognomonic of masturbation. The severe backache of chronic constipation was situated slightly lower, corresponding to the sternal level—the first sacral vertebra. The junction of the dorsal and sacral nerves explained the pain felt in the glans penis in certain cases of carcinoma vesicae and irritation of the vesicae by the presence of stone. In conclusion, Dr. FARWICK propounded two questions for discussion: (1) Was it not possible that the so-called gonorrhoeal rheumatism was a sympathetic advertisement of the urethral condition? The frequency of the left knee being selected, and the intimate relations between the anterior crural and sciatic nerves (which supply the joint) and the sympathetic plexus made this a debatable question. It was true the gonococcus had been found in the pus in the affected joint, but was not that particular joint selected by the nerves connecting it with the diseased part? (2) Ocular fever was so sudden in its development, occurred in the practice of the most scrupulously clean surgeons, and was apparently so unavoidable, that there was a great presumption in favour of a sympathetic origin. If it was due to nervous irritation passing through the urethral nerve supply, the speaker asked whether any had noticed its occurrence after the use of cocaine; and as this method had proved successful with him, suggested that in every case in which a tendency to nervous excitement was suspected, cocaine should be used before catheterisation. He had never seen an attack after perineal section, even when a catheter had been used in for days, and attributed this to the short length of the urethra occupied by the instrument.

SUB-HEPATIC ABSCESS.

MR. JAMES CANTLIE, M.B., F.R.C.S., Surgeon, Seamen's Hospital Society, gives in a paper read at the last Annual Meeting of the British Medical Association, his personal experience of subhepatic abscesses. We extract from the *British Medical Journal*. The cause of this affection is attributed, as in suprahepatic abscess, to inflammation of the lymphatics and possibly the lymphatic glands on the under surface of the liver. The only definite sign was a tumour in the epigastric region along the costal margin, containing pus and having for its boundaries the liver above and an inflammatory thickening of the perihepatic tissues around. As this condition could only be exactly elucidated during an operation, clinical evidence could at most suggest the possibility of such a condition. The local signs and symptoms in the author's cases were: (1) A tumour projecting from the anterior margin of the liver to the left of the falcus of the gall-bladder and behind the right rectus muscle like a full gall-bladder, though situated to the right of the position where the gall-bladder was usually found. (2) Perihepatitis with friction sounds showing an increased area from day to day. As the area extended, friction sounds disappeared from the centre of the dull area, but continued to spread at the margin, showing the formation of central adhesions and a widening in the perihepatic inflammatory area. (3) Hepatitis not marked and area of liver dulness not much, if at all, increased. (4) General symptoms: rise of temperature 3 or 4 degrees, occasional rigors, generally paresis of the intestine or, on the other hand, loose bile-stained stools and the usual disturbance of circulation and respiration. Positive evidence, however, could only be established by operation. The diagnosis was unattended with difficulty. Gall-bladder inflammation was most likely to be mistaken. The history of the case, especially residence in, or a visitation to, the tropics, would guide, but the surgeon should be prepared, when about to operate, to deal with either condition. The pus from the abscess possessed but little

resemblance to liver-pus, being creamy and much like that from an abscess elsewhere in the body.

Prognosis.—Good: no deaths in the author's list of cases.

Treatment.—The usual tapping by a large trocar and drainage by a large tube: incision when adhesions were known to have formed. In respect to the depth to which it was safe to puncture the liver itself, Mr. CANTLIE stated that by a study of frozen sections he had found that in a body with a circumference over the hepatic area of 32 inches the centre of the inferior vena cava was from $4\frac{1}{2}$ to 5 inches off the surface, in a line drawn horizontally from the neighbourhood of the xipho-sternal articulation to the angles of the ribs behind. With this measurement it was not safe to penetrate more than $3\frac{1}{2}$ inches in a horizontal direction. For every inch of circumferential measurement above or below the 32 inches a quarter of an inch could be added to, or subtracted from, the depth it was safe to penetrate. Every puncture of the liver by a needle caused a slight or even a considerable flow of blood subsequently into the peritoneal cavity, as Mr. CANTLIE had been able to prove clinically; but in all probability it was this very flow which contributed to the marked benefits usually following liver puncture. The dangers of hepatic hemorrhage were confined to puncturing the inferior vena cava, the extra hepatic portion of the portal vein, or penetrating a mass of malignant tissue occupying the liver.

BURIED ALIVE: "A VOICE FROM THE GRAVE!"

A WRITER in the *Medical Times and Hospital Gazette* says:—Many people are apt to treat the subject of premature burial lightly, to pooh-pooh it, and, in fact, to declare that the cases recorded exist only in the disordered brains of the narrator. The reason for this is that they have never studied the subject, nor has it come home to them, as in the numerous cases of recovering life and consciousness after being medically certified as dead and laid out for burial. Nevertheless, burial alive is a real danger, and will continue to be so until proper precautions to prevent it are legislatively adopted. Doctors cannot be expected to be infallible: they sometimes make mistakes in the diagnosis of ordinary diseases, and it is especially difficult to distinguish between real and apparent death. All the so-called signs of death, except putrefactive decomposition, are more or less fallacious. Not many days since, an American gentleman, lecturing at St. James Hall, stated that his own child had been pronounced dead by physicians, and to all appearance such was the case, and yet the little patient recovered. A remarkable instance of medical liability to error in the matter of life or death, related by the Right Rev. SAMUEL FALLOWS, of Chicago, missionary bishop of the Reformed Episcopal Church, appeared in the *Weekly Times and Echo* on 8th June last. It would occupy too much of your valuable space to give it as published, but the main facts are as follow:—The wife of a young business man, a woman of strong emotions and most delicate perceptions, became ill, and after a few days of agony, apparently died. There was not the least doubt about it in the doctor's mind. The usual phenomena of death were present, a certificate was made out, an undertaker called in, the body was placed in a coffin, and on the third day buried in a cemetery at some distance from the home. The husband grieved greatly, so much that his relations feared an attack of melancholia, and a cousin stayed the night to cheer him up. After long wakefulness, the sorrow-stricken husband fell into a disturbed sleep and in the middle of the night was awakened by a voice calling, "CHARLES! CHARLES!" It was a dream, he

thought, and went to sleep again, but was, once more aroused by an unfamiliar voice saying, "CHARLES! CHARLES!" Still thinking it only a dream, he again slumbered, when at daybreak he heard and recognised his wife's voice crying in tones of distress, "CHARLES! Save me! CHARLES!" He sprang out of bed, and finding himself alone, rushed into his cousin's room, shouting, "Get up! Get up! We must hurry to the cemetery! She is alive! She is calling me!" Although of a sceptical nature, the cousin was strongly impressed by the man's impetuous conviction. Both hurried on some clothing, and while one harnessed the horse to a light buggy, the other procured spades. Having driven rapidly to the cemetery, they leaped out at the graveside, hastily dug till they reached the coffin of the woman who had been buried the previous afternoon, wrenched off the lid, and found the poor creature feebly trying to turn over in her narrow bed, but quite unconscious. The two men carried her to the buggy and drove home, and under very careful medical attention, the lady slowly recovered from her malady. Bishop FALLOWS says: "I am now engaged in an effort to so adjust matters in the interest of science, that the story may be investigated and its truth made as manifest to the most sceptical as it is to me."

PHYSICAL vs. MENTAL EDUCATION.

THE *Medical Brief* says:—A recent writer argues that tenement children would derive far more benefit from a compulsory physical education than from a compulsory mental education.

From a purely medical standpoint this may be true; but from a politico-social standpoint it is at least open to doubt.

Physical development, without enlightenment and culture, makes men brutal and violent. It breeds forced ideas and methods. Physical development alone hardens men, makes them resistant to the forces of disease and suffering at the expense of character growth. To make physical education of prime importance may be all right for military nations, who maintain immense standing armies; but in America individualism is the corner-stone of civilization.

Physical exercises and sports, in moderation, to develop the body symmetrically, and place all its parts under control of the will, are excellent for health; but even this can be dispensed with rather than neglect the mind.

Enlighten the mind, teach it to think logically, and it will find ways and means to release the body from the bondage of ill-health and weakness. Mere muscular strength is brute strength, and brutalizes the aims, ambitions, tastes, etc., of those who possess it. Men find their chief pleasure in the exercise of their best developed powers. It is easier to develop muscular force than intellectual force, the former being lower in the scale of development.

This fact has been instrumental in bringing about a reaction against college athletics. Instead of making athletics a means to an end, to keep the body in health and take off nervous tension, students have shown a growing tendency to make athletics the particular feature of college life at the expense of the studies.

Physical exercise of a varied nature, sufficient to circulate the blood freely and relieve obstructions, to promote elimination and keep all muscular structures in a tonic condition, is helpful; but any greater expenditure of vitality in this direction, except what may be necessitated by occupation or circumstances beyond our control, is wasteful and injurious.

COLONIAL MEDICAL QUALIFICATIONS AND THE BRITISH MEDICAL REGISTER.

THE *British Medical Journal* says:—In a letter signed "ONLOOKER," addressed to the *Western Morning News*, the mistaken statement is made that the War Office is unable, under the Medical Act of 1858, to recognise any medical degree not obtained in this country, and an attempt is made to rouse popular indignation against the "obsolete Act" by inferring that the welfare of our troops in South Africa was thus imperilled. Medical readers will of course know that the statement and inference are quite erroneous. Medical practitioners with Colonial degrees not only served with the troops during the Boer war, but are still serving as medical officers in that war, which still continues, although the correspondent to whose letter we have referred styles it "the late war." The *Medical Register* now contains a Colonial List, upon which can be found the names of medical men who have obtained degrees in certain Colonies. The correspondent has fallen into the error by not remembering or not knowing that the Medical Act of 1858 was amended by an additional Act of 1886. By this amended legislation, where a person shows to the Registrar of the General Medical Council that he holds a recognised Colonial medical diploma or diplomas (as hereinafter defined) granted to him in a British possession to which this Act applies, and that he is of good character, and that he is by law entitled to practise medicine, surgery, and midwifery in such British possession, he shall, by application to the said Registrar, and on payment of such fee, not exceeding £5, as the General Medical Council may from time to time determine, be entitled, without examination in the United Kingdom, to be registered as a Colonial practitioner in the *Medical Register*. In the Act power is given to Her Majesty through the Privy Council to define from time to time the Colonies to which the Act shall apply; but it is laid down that the Colony must afford to the registered practitioners of the United Kingdom such privileges of practising in the Colony as to Her Majesty may seem just. The Colonial medical diploma which is to be registered must be recognised by the General Medical Council as furnishing a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery. The current issue of the *Medical Register* contains the names of eight Universities and one College in British possessions granting degrees which are registrable in the Colonial List. These are the Universities of Sydney, Adelaide, Melbourne, and New Zealand in Australasia; the Universities of Bombay, Calcutta, Madras, and the Punjab in India; and the Ceylon Medical College.

FACTS REGARDING CRIMINAL ABORTION.

We quote the following from the *Medical News*:—Dr. DUNSTON LEWIS estimates that 80 per cent. of all married women who become pregnant wish they were not. Old ladies recommend the use of different teas, hot douches, hot baths and violent exercise. Cathartics, emmenagogues, and ergot are advised, and among the ignorant, arsenic, metallic mercury or other poison has been taken, usually with fatal result. These means often fail. Cases are cited where women fell from great heights, sustained fractures, were beaten to unconsciousness, and suffered even fatal traumatism without severing connection between mother and child. At other times very slight injury produces abortion. Alum water injections have caused death. One woman produced abortion upon herself thirty-five times with a knitting-needle. Death has occurred simply from the introduction within the uterus of a cannula. The intra-

uterine injection of glycerine has proved fatal. An embolism has occurred, also mercurial poisoning, from a bichloride douche. The uterus is not always entered by the foreign body. THOMAS's case is cited in which a physician's wife passed an umbrella rib through the vaginal vault, the abdominal cavity and diaphragm until it perforated the lung. Other cases are instanced where an elastic sound entered the cervix for two and one-half years, and where metastatic abscesses formed in brain and elsewhere. LEWIS cites a case of his own, in which a silver catheter had perforated the posterior uterine wall and was removed from under the liver by abdominal section. In this case the pregnancy was uninterrupted. Other cases show a glass rod retained in the broad ligament, a seatangle tent found posterior to the uterus, a needle seven cm. long observed in omentum during the performance of CESAREAN section. Sometimes no discomfort results, at other times a suppurative process causes its expulsion into adjoining viscera. A fatal injury of the internal iliac artery is recorded. Utero-intestinal fistula has occurred. Two cases are instanced where a knitting-needle was forced through the umbilicus into the uterus. The relation of repeated abortion to degenerative changes and diseased states of the nervous system is considered as well as the production of sterility by infection of the tubes.

DEATHS FROM WILD ANIMALS AND SNAKES IN INDIA.

"THE element of tragedy is nowhere more apparent in the reports issued by the Government of India than in the annual return setting forth the terrible mortality caused among human beings and cattle by the depredations of wild animals and snakes." So says the *Times of India*, and proceeds to give the following details:—"Last year 2,966 people died from attacks by wild beasts, while the enormous number of 24,621 deaths from snake-bites was recorded. The Bombay Presidency only contributed 1,148 to this total, of which 26 were deaths from animals, the remainder being due to snakes. Bengal is by far the greatest sufferer, for the province figures in the returns as having lost 1,632 people through wild beasts and 12,220 through snakes. The relative destructiveness of the different animals is revealed in a table showing that during the year 899 persons were killed in India by tigers; 338 by wolves; 327 by leopards; 95 by bears; 40 by elephants; 27 by hyenas; and 1,230 by "other animals," chiefly jackals and crocodiles. Tigers are so destructive in Bengal that the desirability of devising special expeditions for their extermination was considered by the local Government, but it was eventually decided to leave the matter to local enterprise, 'stimulated by the offer of liberal rewards.' In the district of Gaya a local committee has offered Rs. 300 per head for man-eaters, while Rs. 200 is now paid in Ranchi and Singhbhum. In the Bhamo district of Burma a single man-eating tiger is said to have killed twenty people, and the ravenous brute must be held to have been cheaply killed at Rs. 100. Another tiger was responsible for the deaths of twelve persons in the North Cachar Hills in Assam. In the North-Western Provinces 271 people were destroyed by wolves, which are particularly plentiful and dangerous in that part of India. The numbers, however, were considerably lower than was the case in 1896 and 1897, when the prolonged drought and scarcity made the wolves unusually daring. The exceptional mortality from snake-bite in Bengal is attributed to floods, which drove the snakes to the high lands on which village homesteads are built. Nearly a hundred thousand head of cattle were killed by

wild beasts and snakes during the year, of which total all but 9,449 were due to animals. Leopards killed 37,988 of this number, and in Bengal inflicted far more loss upon the herds than tigers. The work of exterminating these various dangerous pests went on pretty much as usual. Thus, 1,570 tigers were killed, 4,548 leopards, 3,317 wolves, 776 hyenas, and 94,548 poisonous snakes; but in the fierce battle between man and the lower orders of creation in India, the balance of victory continues to incline towards the beasts.

BAD SPELLING AND CARELESS DISPENSING CAUSE DEATH.

An inquiry was opened at Portfield, near Chichester, on November 30, into the circumstances of the death of a six months' old infant, AGNES MARY LEGGATT. The child had recently been vaccinated and the arm was sore and swollen. Dr. BUCKELL, who was called in, prescribed an antiseptic powder, which his dispenser (Mr. WIDALL) made up. The dispenser cautioned the woman about the use of the powder, telling her it was poisonous, and on the box the words "Poison (underlined) powder" were written. A quantity of the powder was dusted over the child's arm, and she went to sleep and never woke up again. Dr. ARTHUR EDWARD BUCKELL, in the course of his evidence, said he wrote a prescription for "Urophen and boracic acid," and took it into the surgery to be dispensed. The former word, he said, was also spelt "Eupraphen," but he had always been accustomed to spell it without the "e." The word, as he wrote it, bore a resemblance to "morphia," and thus a mistake had arisen. Mr. WIDALL (the dispenser) stated that he made up the prescription as he read it—"morphia, one scruple, boracic acid, two drachms." Nothing unusual struck him in the reading of the prescription as "morphia and boracic acid." He now understood the first word to have been intended for "urophen," but there was no "e" commencing the word.

At the adjourned hearing on December 8 the jury returned a verdict of death by misadventure, and expressed the opinion that more care should have been used in writing the prescription, and that the dispenser would have done better had he referred the prescription to the doctor before making it up.

REMOTE RESULTS OF CONSERVATIVE OPERATIONS ON THE OVARIES AND TUBES: AN ANALYSIS OF EIGHTY-FIVE CASES.

DR. W. L. BURBAGE (*Annals of Gyn. and Pediat.*) says:—

1. It is advisable to do conservative operations in all cases where the ovaries and tubes are not hopelessly diseased in all parts of their structure, except on patients who are near the menopause, or patients who have pronounced gonorrhoea of long standing, and on the rare cases of malignant disease.

2. If one tube is patent and healthy in appearance, and there is enough healthy ovarian tissue to preserve, a conservative operation ought to be performed, even in the presence of gonorrhoea.

3. In well-marked gonorrhoea of long standing, if both tubes are seriously diseased and closed, total removal with or without hysterectomy is the operation of choice.

4. If it is necessary to remove both ovaries, it is of no advantage to preserve any portion of tubal tissue, but, except under the conditions just enumerated, some ovarian tissue should be preserved in every case.

MURDER OF CAPTAIN JOHNSTON, I.M.S.

THE following particulars are in hand regarding the murderous outrage at Loralai. The deceased officer, Captain JOHNSTON, Indian Medical Service, was in medical charge of the 24th Bombay Infantry cantoned there, and held the additional appointment of Civil Surgeon, in which capacity he was returning to the cantonments on foot after visiting the civil dispensary at eleven o'clock on Wednesday morning accompanied by the hospital assistant in charge thereof, when, from the opposite hillock just outside the civil bazaar, behind which the latter dispensary is situated, the fanatic rushed at him with a drawn sword. The hospital assistant bolted, while Captain JOHNSTON, though quite unarmed, stood his ground. Having his right arm, which he must have raised for protection, cut clean off at the first blow, he was then hacked about the head. Death is believed to have been instantaneous. The fanatic afterwards pursued the hospital assistant a short distance, then turned off into the bazaar, where he was pluckily tackled by a fellow tribesman employed as jemadar of the levy. A chowkidar knocked him down and pinioned the assassin. As a Vamsa Kakar from the village Wahar near Loralai, he had returned from Kandahar three months previously. He will be tried when he recovers from the high state of nervous excitement in which he is at present medically reported to be. Captain JOHNSTON'S funeral came off on the evening of his death, and was attended not only by the few Europeans stationed at Loralai and the usual military escort, but by his whole regiment, and a tremendous concourse of natives of all ranks, classes and creeds. It may be noted that a Bengal Lancers regiment is also cantoned at Loralai, which is likewise the residence of the ex-Khan of Khelat.

MOSQUITOES AND MALARIA.

THE *Practitioner* says:—LAVRAN'S discovery of the plasmodium of malaria was long ignored; then the credit was given to some one else. In the same way the mosquito theory has been claimed for Americans, Italians, and others; and, of course, for the noble savage, whose untutored mind seems not infrequently to see things hidden from the bespectacled eyes of science. In KOON'S extraordinary reports from German New Guinea no mention is made of any other investigator; the subject is treated as if he were the COLUMBUS of an unknown continent of knowledge. KOON has been a great scientific conqueror, and is fully entitled to his triumph. But the way in which he drags at his chariot wheels the discoveries of other men is ultra-Germania in its insolence of self-assertion. In this particular field of research our German friends have done nothing at all. LAVRAN proved that malaria is a parasitic disease; MAXSON and ROSS have shown how the parasite is conveyed to man. The Italians have worked out certain details of the problem by following the course indicated by the British workers; but the credit of the solution belongs to our countrymen.

NEW CALCUTTA UNDERGRADUATES.

THE undermentioned candidates have passed the Second L. M. S. Examination:—

Bandyopadhyay, Prabodho Chandra; Bhattacharyya, Ganiprasad; Bhattacharyya, Sanadiprasad; Bhattacharyya, Satyendranath; Bhattacharyya, Hemachandra; Chaudhuri, Bijaykrishna; Datta, Manindrachandra; Datta, Nisanath; Datta, Parasath; De, Jaharaj; Ghosh, Basantakumar; Mandal, Purnachandra; Mitra, Guruprasad; Mukhopadhyay, Amulyakumar; Mukhopadhyay, Debendranath, I; Mukhopadhyay, Debendranath, II; Mukhopadhyay, Digamkrishna; Mukhopadhyay, Gupendranath; Mukhopadhyay, Naradranath; Mukhopadhyay, Prabhathath; S. M. Habibur Rahman.

SELF-DENIAL.

There may be glory in the night
That treadeth nations down—
Wreaths for the crimson warrior,
Pride for the kingly crown;
More glorious is the victory won
O'er self-indulgent lust,
The triumph of a brave resolve
That treads a vice in dust.—J. G. WHITTIER.

POISON IN BEER.

The flood of daily newspaper comment upon the Lancashire beer-trouble is unabated, and a brewers' commission, consisting of Sir Lauder Brunton, Dr. Thomas Stevenson, Mr. Gordon Salamon, Dr. A. P. Luff, and Dr. Buckley, has discovered that an invert sugar supplied by a certain company contains arsenic. This confirms Mr. Kirkby's observation. The commission has recommended that no beer should be sent out until it has been tested and shown to be free from arsenic. A certificate of freedom from arsenic should be given in respect of beer so tested, and only such beer should be sold.

I. M. S. OFFICERS AND LEAVE.

The continued stoppage of leave in the Indian Medical Service is pressing very hardly on a department which has long been overworked, plague, famine and military expeditions having combined to increase the labours of the medical officer. With no less than a hundred and twenty members of the service, however, told off on duty connected with the operations in China, there are not enough left to carry on ordinary duties in India, and at the same time to furnish the usual contingent for furlough. The re-opening of leave thus depends on the return of the officers from the China force; and now that the winter has set in, and active operations about Peking are suspended, it may become possible to spare a good many.

SHORT ITEMS AND PERSONALITIES.

The retirement from the 15th instant is notified of Lieutenant-Colonel G. M. J. Giles, I. M. S., Bengal, who will be specially remembered in connection with his investigation of *Kala-azar* disease in Assam, his scientific researches on the subject of the deep sea fauna of the Bay of Bengal, and of the mosquito in relation with malaria. He will be missed amongst a very wide circle of friends alike in Bengal, the North-West Provinces and Bombay.

Sir William Thomson has been asked by the Lord-Lieutenant of Ireland to remain Surgeon to the Household during His Excellency's stay in Ireland. Sir William having been recently appointed Surgeon to the Queen in Ireland, in the room of the late Sir William Stokes, had vacated the Surgeoncy to the Household. Sir William Thomson has been re-elected to his seat on the Council of the Royal College of Surgeons, his absence in South Africa having rendered void the election in June.

The ceremony of the presentation of the Kaiser-i-Hind silver medal to Dr. Cardox, Assistant Civil Surgeon and Vice-President of the Hubli Municipality, was performed on the 20th December in the Municipal Hall. The hall was tastefully decorated for the occasion. There was a crowded attendance.

The services of the following I. M. S. officers have been temporarily placed at the disposal of His Excellency the Commander-in-Chief in India:—Lieutenant-Colonels Danton (Bombay); Sarkies (Madras); Vaid (Bengal); Major Pissani (Bengal); Captains Vickers (Madras); Newman (Bengal); and Lane.

Dr. Martin J. P. Dempsey, F. R. C. P. I., Visiting Physician to the Mater Misericordias Hospital, Dublin, has been elected to the Chair of Materia Medica and Pharmacy in the Catholic University School of Medicine, rendered vacant by the death of Dr. F. J. B. Quinlan.

The hospital ship *Gwalior* will leave Calcutta for China about the 25th instant. She is being fitted up to accommodate European invalided troops in addition to Indian troops. Colonel Crofts, I. M. S., will continue to have chief medical charge.

Dr. Mohendra Lal Sircar, we are sorry to hear, is seriously ill and has been confined to his bed since the 2nd of January. He is suffering from urinary difficulty and fever due to the enlargement of the prostatic gland.

WANTED—A THIRD GRADE HOSPITAL ASSISTANT to come to Burma on mutual transfer with the undersigned. Any one from Punjab or N.W. P. will be accepted. For particulars, address:—

H. A.,
C/o Manager, "Indian Medical Record."

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE INDIAN MEDICAL RECORD will, upon publication, be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary, to elucidate the text, illustrations will be provided without cost to the authors. Address the Editor, JAMES R. WALLACE, M.D., F.R.C.S., 50, PARK STREET, CALCUTTA.

NOTICE.

All members of the Indian Medical Association are kindly requested to send their names in full with their present addresses, clearly written, to the Secretary.

Members who have paid their subscriptions and who have not received the membership certificates are kindly requested to notify the same to the Secretary.

Subscribers are requested to communicate any temporary change of address not to the Office of this Journal, but to the post-office through which they are accustomed to receive their Journals.

The Indian Medical Association fights the battles of the Medical Profession as a whole, and it takes up the cause of individual members as well. Join the Association and you will not be disappointed.

Medical Appointments, Transfers, Exchanges are easily and cheaply effected through our special short advertisement page. See terms and apply at once.

The *Indian Medical Record* offers the following prizes:—Rs. 10 to Rs. 16 for a good Original Article; Rs. 5 to Rs. 10 for a good Clinical Report. Competitors must be subscribers to the *Record*.

Members of the Indian Medical Association will kindly note that while the entrance fee to the Association is fixed at Rs. 5, the annual subscription is reduced to Rs. 2.

News items of medical interest from all parts of the Indian Empire are asked for by the Editor for publication in the *Record*.

Current Medical Literature.

MEDICINE.

Treatment of Typhoid Fever.

D. E. ENGLISH, M. D., *New York Medical Record*, says:—In the treatment of typhoid fever we should ever bear in mind the nature and probable cause of the disease, for treatment directed to the relief of the symptoms only is not so uniformly successful as a combined, systematic and specific treatment. From this standpoint the writer states the following indications for treatment:—

- (1) To empty the gut of all infected matter as soon as possible.
- (2) To render the gut as nearly as possible uninhabitable by the microbes.
- (3) To prevent, as far as possible, the further absorption of the poison.
- (4) To neutralise or expel the poison already absorbed.
- (5) To keep the temperature within safe bounds.
- (6) To prevent, so far as possible, over-action of organs already damaged, i.e., to promote physiological rest, and avert rupture of the intestine.
- (7) To support the strength of patient, and guard against sudden collapse.

To secure the first three of these *desiderata*, purgation is recommended, an initial purge of calomel gr. x. to xxx., according to circumstances. If free catharsis is not secured by these means within six hours, magnesium sulphate 3i hourly is given. The treatment is then continued by administering podophyllin gr. $\frac{1}{2}$ to $\frac{1}{4}$, aloin gr. $\frac{1}{4}$ to $\frac{1}{2}$, every night and morning. The favourite intestinal is carbolated camphor. One ounce carbolic acid crystals and three ounces of camphor gum are put together in a glass vessel and allowed to stand a short time. A smooth transparent oily liquid is obtained, almost colourless at first, changing to a light pink with age. It is best given by dropping the dose into a capsule just before it is administered.

Ten to twelve drops may be given every two hours for forty-eight hours before there will be any change in the colour or odour of the urine, when it should be given less frequently, or the dose decreased. It need not be stopped for slight albuminuria.

Large and frequent draughts of sterile water are most valuable in neutralising the absorbed poison and expelling it from the body.

Temperature is controlled by the carbolated camphor in most cases. The author aims at obtaining an action of the bowels once or twice a day; if the patient is taking milk, four or even five movements a day seem to do no harm.

When it becomes necessary to check the bowels, which is seldom the case, small doses, gr. iiss. of Dover's powder are used. To prevent cardiac fatigue, absolute quiet should be maintained. When the pulse is rapid and soft, small doses of tincture of digitalis (about m. v.) in whiskey (about 3i.) may be given tentatively every four hours.

For diet during the first two weeks dissolved beef is relied on entirely. This is made after WEIR MITCHELL's formula. During the third week one pint of milk may be given every 24 hours in divided doses, largely diluted with sterile water, and with the addition of as much salt as will be palatable. Also the white of one egg in water, and one

entire egg beaten with the juice of one lemon, may be given each 24 hours.

Later, changes in diet are made at the physician's discretion.

[The comprehensive aim of treatment enunciated in this paper is more commendable to practitioners in this country than the means, chiefly by purgation, employed to attain it. Eliminative treatment by purgatives has few advocates in England.]

Puttee Paralysis (?) after Enteric Fever.

J. W. SPRINGETHORPE reports the case of a soldier who suffered from a condition frequently seen in that class after typhoid. Examination disclosed marked wasting of the tibial muscles of the left leg, with apparent wasting of the peroneal and extensor muscles also. The muscles reacted to the faradic current, but with a noticeable weakness. Those on the right leg showed no present difference or abnormality. There had been no implication of the calf muscles, and there was no present tenderness on pressure over the nerve trunks in that region. Under faradism and massage the muscles rapidly regained their normal reactions, and their action at the time of writing has become practically perfect. The trouble was thus confined absolutely to the muscles and surfaces supplied by the peroneal nerve, the musculo-cutaneous branch of which supplies the peroneus longus and peroneus brevis, together with the dorsal surfaces of the foot and toes, while the anterior tibial branch supplies the tibialis anticus, the long and short extensors of the toes, and the long extensor of the big toe, as well as the dorsal surfaces of the inner toes. This implication of the peroneal nerve suggested injury, and when symmetrical, bilateral pressure as the probable cause. Such a cause is at once suggested in the puttees used so extensively and indiscriminately by the soldiers in the South African campaign. On being asked, the patient stated that the last few rounds of the puttees were fastened rather more tightly than elsewhere directly over the head of the fibula, and thus pressed the peroneal nerve against the bone.—*The Lancet*.

Forms of Tremor, and their Clinical Characters.

R. T. WILLIAMSON states that the relation of tremor to voluntary movement enables us to arrange the cases into three groups; but there are other sub-varieties. (1) Tremor occurring during repose of the limb, but ceasing or diminishing on voluntary movement, with attention tremor which ceases when an object is grasped, or when the hands are held out. The tremor in paralysis agitans is usually of this form. (2) Tremor occurring only on voluntary movement and ceasing during repose (intention tremor). This is the form of tremor in disseminated sclerosis, even at an advanced stage; but several other forms of tremor, at a very early stage, occur only on voluntary movement. (3) Tremor which occurs during repose, but which is much greater during voluntary movement; as in most cases of marked alcoholic, senile, asthenic, simple, and hysterical tremor, and in several other varieties.—*The Medical Chronicle*.

SURGERY.***Tuberculous Lesions from a Clinical Point of View.***

EDMUND OWEN, M.B., F.R.C.S., in the *Canada Medical Record*, makes the following statements: "(1) Chronic inflammation of a joint in a child or young person is always tuberculous, except in those very rare cases in which it is due to hereditary syphilis or osteo-arthritis. (2) Tuberculous inflammation may completely destroy a joint, and then leave it solidly and soundly synostosed, without the surrounding tissues or the skin having been implicated. (3) If tuberculous granulation tissue breaks down into a fluid, that fluid is not pus, and the collection is not, properly speaking, an abscess, unless by bad fortune, or by worse surgery, it has become infected by septic micro-organisms. (4) The fluid collection is not to be treated as an abscess—by incision and drainage, that is—but is to be opened and emptied and scraped and cleansed of its unhealthy lining of granulation tissue. Then the wound in the skin is to be completely closed by sutures; firm pressure is to be evenly applied, and the part is to be kept absolutely at rest. It is no news to most of you to be told that the success attending this line of treatment leaves, as a rule, little to be desired, or that for this important advance in practical surgery we are chiefly indebted to the patient researches of our friends with the smock frocks and the guinea-pig. (5) I have failed to discover that iodoform is of any peculiar value in the treatment of tuberculous lesions. At any rate I have long since discarded it, and I have not noticed any falling-off in the results of my practice in consequence. Iodoform is an irritant and a poison, it is apt to be septic, as germ can grow upon it; but I have no knowledge of the truth of the statement that mushrooms have actually been cultivated on it."

Total Gastrectomy.

V. DE CARVALHO (*Lancet*) records the case of a Brazilian mulatto woman, aged forty-six years, whose emaciation had advanced so continuously that she weighed but sixty-eight pounds; she had always suffered more or less from gastric pains since her youth, with recurring attacks of gastralgia followed by vomiting (occasionally of blood); becoming more frequent and severe. On examination a tumor, the size of a turkey's egg, was found in the right epigastric region close to the costal margin, the tumor being moveable and painless on deep pressure; a median excision extending from the xiphoid cartilage of the sternum to the umbilicus was made and the tumor exposed; owing to the adhesions of the stomach to adjacent viscera, gastro-enterostomy which had been contemplated was deemed inadvisable; hence gastrectomy was decided upon and performed in the usual way, great difficulty being experienced in enucleating the stomach and in approximating the duodenum to the esophagus. Although the patient's condition was poor during the operation, requiring stimulation, and the introduction of artificial serum intravenously, the patient came out from the operation nicely; rectal feeding was continued for six or seven days; at the end of the ninth day the superficial wound had healed and the patient was able to take small portions of solid food, which were readily digested. This is the fourth successful operation thus far recorded, being the first one to be done successfully in Brazil.

Operative Treatment of Ugly Ears.

JOHN B. ROBERTS believes this subject particularly worthy of attention, since the operative treatment for the correction

of these conditions is free from risk and generally unaccompanied by confinement to bed or even absence from business pursuits. A lacerated or incised ear may be so carefully sutured that the shape of the organ may be well preserved even after considerable loss of structure. After the removal of tumors, or the occurrence of sloughing from burns or traumatism, it may sometimes be necessary to alter the shape or size of the uninjured ear to make it correspond with the injured member. If new tissue is demanded to replace that which has been lost, it may be transferred from the neck or cheek, or transplanted from the hand, abdominal wall, or thigh. Orthopedic measures are applicable in some cases—pads, springs, or repeated use of collodion. Artificial ears of celluloid papier-mache, or platinum, properly tinted, may replace an absent member; or repeated plastic operations may suffice to restore some semblance of the original ear. Congenital nodules are to be excised as a rule. Very large ears may be reduced by excising a wedge-shaped piece, or by taking a crescentic piece from the central part of the auricle and a horizontal strip outward from the centre of the convex margin of the crescent. Flaring ears are corrected by excising a vertical ellipse of skin and fascia from the posterior surface of the auricle and the adjacent part of the skull and then cutting a vertical wedge-like strip from the exposed cartilaginous structure of the ear. The auricle is then sewed close to the skull. In lap ears the suggestion is made of stiffening the auricle by inserting a thin sheet of metal in the tissues, after which it might be bent to the normal shape of the organ.—*Med. News.*

Operating on the Prostate.

CLARKE advises, in operating on the prostate, that the operation be done at two sittings. At the first the bladder is opened suprapubically and a couple of stitches passed through the bladder wall, one on either side, and a good-sized tube left in the suprapubic opening to prevent so much contraction that the surgeon would not be able to pass his finger into the bladder for examination. The drainage of the bladder thus established allows the patient to rapidly improve in health, and in a week or ten days he is ready for the second part of the operation. This time an incision is made in the perineum as for lateral lithotomy, until the prostate is reached. The finger of the left hand is then introduced into the suprapubic opening, and the prostate pushed down towards the perineum, which procedure greatly aids the removal of the gland itself. The hemorrhage in all the cases reported was insignificant, this being attributed to the subsidence of the congestion around the prostate and the base of the bladder, occurring between the two operations.—*Phil. Med. Jour.*

Traumatic Joints.

HOMER GAGE concludes his paper on this subject as follows: (1) All injuries to joints accompanied by loss of function are always attended by more or less laceration of the tissues in or about the joint. (2) The delays in the restoration of function are due in most instances not to any complicating diathesis, but to the changes incident to the repair of these lacerations and their effects. (3) Such delays are best avoided by an early resort to massage and active or passive motions, and are favored by too long a continuance of rest and fixation. (4) When such delays have occurred, they are best overcome by more vigorous and persistent manipulation, supplemented by the application of heat or such other agents as may best stimulate the local circulation and favor the elasticity of the tissues.

OBSTETRICS AND GYNÆCOLOGY.**Extraction of Living Twin 19 Minutes after Death of Mother.**

KIRCH was called in by the friends of a shopkeeper's wife who, they said, had just died suddenly three-quarters of an hour after giving birth to a child. She was 40 and subject to mitral disease, the result of rheumatism. Very grave cardiac symptoms had developed at the end of the previous pregnancy. KIRCH at once visited the patient, who lived close to his house; he found her quite dead; much sanious mucous had run out of her mouth on to the pillow. A nurse was attending the new-born child. KIRCH found a foetal leg projecting from the vulva. He at once extracted the foetus—it was asphyxiated, but was revived; however, it died within a few hours. On the evidence of KIRCH and the nurse the second twin was delivered just 19 minutes after the death of the mother. The husband stated that the patient had calculated term at three weeks later. She was working in the shop till 10 P. M.; a few minutes later pains set in, then the membranes ruptured. She was speedily put to bed and the child was at once delivered spontaneously. Dyspnoea then set in, lasting for some time, when the woman suddenly ceased to breathe, froth escaping from the mouth. KIRCH arrived a little before midnight.—*Brit. Med. Jour.*

Normal Labour after an Unnecessary Cesarean Section.

BISSEL publishes clinical details of a case very grave from an ethical aspect. A married woman, aged 19, and pregnant, was subject to prominent coccyx. Her physician did not even make an effort to deliver her with forceps; he had satisfied himself several months before term that the child could not be born through the genital canal, and openly declared that the long-looked for opportunity of his life had arrived. He performed CÆSAREAN section, and afterwards advised the patient to have her uterus removed, for another pregnancy, in his opinion, would kill her. She consulted BISSEL about two years after the operation. The pelvic measurements were perfectly normal. The coccyx was slightly sensitive to pressure, and inclined considerably forward, but it was moveable and did not diminish materially the antero-posterior diameter of the outlet. A few months later she became pregnant. BISSEL attended her in labour. He found the pains strong, the head presented in the right occipito-anterior position. But a few hours later, as the head did not descend well and the pains were weak, he ruptured the membranes. This did not stimulate uterine action much, so the forceps was applied, and the child, which weighed a little under eight pounds, was delivered with comparative ease. The perineum was lacerated, but immediately repaired. Mother and child did well. Thus the previous operation, though utterly unjustifiable, did no more harm than to cause slight atony of the uterus.—*Brit. Med. Jour.*

Symphiseotomy.

THE dangers of symphiseotomy, according to CARR are: (1) Dangers from anaesthesia and from shock, which are unavoidable. (2) Danger from infection, which is unnecessary but real. (3) Danger of attempting it in unfavorable cases where the pelvis is too small. He goes at some length into the discussion of this subject. (4) Danger of lacerating the bladder or uterus or the sacro-iliac ligaments. This can be avoided by insuring not over two and a half inches separation in all cases, and there will then be no laceration of tissues excepting some peeling off of the periosteum. (5) Danger of hæmorrhage from rupture of the anterior vesical veins or those of the clitoris. Usually this may be checked by gauze packing, but may be entirely obviated by separating the tissues carefully all around the symphysis, and for three-quarters of an inch to one inch on each side of the median line. (6)

Danger of sepsis, and the failure on special antiseptic precautions, using 1-2000 bichloride solution freely. (7) Discomforts and dangers that may follow from the imperfect methods of coapting the bones, which he thinks can be obviated by wiring the joints. This should be done in every case. The two cases he reports are not enough to base an opinion upon, but they show that wiring the bones does not necessarily produce any bad results. The contrast between the cure where wiring was used, and that where it was not, is most marked, and until this becomes part of the operation, symphyseotomy will not meet with general favor.—*Jour. Amer. Med. Assoc.*

Cervical Metritis.

POZZI presents the following conclusions on this subject: (1) Acute or chronic inflammation of the cervix can exist for a long time without invading the body of the uterus. (2) Nevertheless, the acute lesions of the cervical mucosa easily extend to the mucosa of the body, and the chronic lesions of the cervical parenchyma of inflammatory origin (sclerous and sclerotic degeneration, partial or total) promptly react on the nutrition and anatomical condition of the entire uterine body. (3) The operation of trachelorrhaphy is inferior to the biconical resection of the cervix, more or less modified according to circumstances. It ought to be abandoned. (4) There are a large number of acute, sub-acute, or chronic inflammations of the cervical mucosa in nulliparæ, which are dependent on the narrowness of the external orifice, and on the insufficient drainage resulting therefrom. The most important part of the treatment is then to reconstruct by operation in a durable manner an orifice large enough for the cervix.—*Annales de Gynecologie et d'Obstetrique.*

Operation devised for the Treatment of Marked Prolapse of the Rectum in Women.

J. WESLEY BOYER says:—The patient was a woman, aged thirty-five, who suffered from large external and internal hæmorrhoids and a protruding roll of fully three inches of rectum that was thickened and much discolored. The uterus was of about normal size, with its cervix just behind the pubes and the fundus very low posteriorly. The hæmorrhoids were first removed, then the abdomen was opened by the usual sub-umbilical median-line incision. The left ovary was of about three times its natural size and largely consisted of numerous cysts. The appendages were removed and the uterus was firmly fixed to the abdominal wall by four strong interrupted catgut sutures, which passed through a considerable portion of the uterine fundus at the top, and the principal fascia of the abdominal wall on either side of the incision. The rectum was now drawn upward until it was fairly tense, and was so held by an assistant until it was sutured to the *cul-de-sac* and posterior wall of the uterus, up to the abdominal wall. This was done by a running catgut suture. It completely divided the retro-uterine pelvic cavity into two equilateral ones. The patient was doing well eight months after operation, with no relapse.—*New York Medical Journal.*

Compression of the Ureters by Myomata Uteri.

THE conclusions of KNOX's article are given as follows: (1) Some compression of the ureters is produced by a large proportion of all large myomatous uteri. (2) The resulting hydro-ureter and hydro-nephrosis may continue for years and give rise to no discomfort to the patient. (3) The presence of a dilatation of the ureter and renal pelvis, however slight, lowers the resistance of these organs to toxic and infectious agents, and hence inflammatory conditions of the ureter and kidneys not infrequently follow ureteral compression. (4) In all instances of uterine myomata, the possibility of urethral involvement must be considered. When such a condition is suspected, every effort should be made by means of direct examination—urethral catheter, etc.—to arrive at an accurate diagnosis. (5) Exploratory incision is occasionally justified to establish a diagnosis. (6) The ureters should be inspected whenever the abdomen is opened for the removal of a tumor. (7) A myomatous mass found to be existing under pressure upon one or both ureters should be removed, if possible, unless operative interference is contraindicated. Such serious sequelæ of ureteral compression as extreme hydro-nephrosis, pyelo-nephrosis, etc., should receive appropriate treatment.

PHYSIOLOGY, PATHOLOGY, AND BACTERIOLOGY.

Physiology and Pathology of Inheritance, or what do we inherit from our Parents?

THOMAS OLIVER says that, from a physiological point of view there is considerable evidence to show that mental, not less than physical, qualities are transmitted; that pathologically such a disease as hæmophilia is inherited, and that, when there is a family history of phthisis and cancer, there is, especially as regards phthisis, a greater liability to the disease than when a family shows no such record. He believes that the influence of inheritance, however, has been exaggerated. Tuberculous disease is inherited, but only in the same sense as are other diseases that are due to microbes: it is in the form of an enfeebled resistance on the part of the tissues. Pulmonary phthisis seems to exhibit a kind of inheritance that is particularly its own, but on scrutiny this is found to be largely due to the domestic character of the malady which is encouraged by our home life, insanitary dwellings, overcrowding of the poorer working-classes, infection, Britain's changeable climate, dusty occupations, and ill-assorted marriages.—*New York Med. Rec.*

Bile in the Urine.

DR. WALSH, in a recent clinical lecture, gave the following simple plan of detecting bile in the urine: "A considerable quantity of urine, from six to eight ounces, is allowed to pass through a piece of white filter-paper. This is then spread on a plate and touched with a glass rod that has been dipped in crude nitric acid. A play of colors develops, green forming the outermost ring. This test is very delicate."—*Journal of Medicine and Science.*

Value of Blood Examination for Diagnostic Purposes.

JULIAN WALTER BRANDEIS first considers the diseases in which blood examination is essential to diagnosis. These he enumerates as: chlorosis, secondary anæmia, pernicious anæmia, leukaemia (both myelogenous and lymphatic) HODGKIN'S disease, anæmia infantum, pseudo leukaemia, malaria, relapsing fever, and færia sanguinis hominis. As characteristic of the blood of children, the writer mentions the following points: A leucocytosis, polycythæmia, and increased percentage of hæmoglobin are characteristic of the blood of the new-born, but gradually disappear. Any influence retarding the child's development causes a leucocytosis, a large percentage of the corpuscles being lymphocytes, and the appearance of nucleated erythrocytes without necessarily the co-existence of an anæmia. Also, in the anæmias of infants and children, the red cells are destroyed to a greater extent, and degenerative changes are more marked than in like cases in adults. Nucleated erythrocytes and myelocytes are more common than in anæmias of corresponding severity in adults. In certain cases the discovery of the etiological germ in the blood has rendered the diagnosis of the following diseases positive: Typhoid, tuberculosis, tetanus, ulcerative endocarditis, anthrax, grippe, glanders, septicæmia, pyæmia, and pneumonia. The writer then speaks of diseases in which blood examinations are an important aid to differential diagnosis and prognosis. For example, both in pneumonia and diphtheria the absence of leucocytosis in any but the mildest cases is a bad sign. NEUBER is quoted as stating that in deciding whether a case of hysteria, neuritis, or psychosis would be benefited by castration, the presence of a eosinophilia suggests the affirmative.—*New York Med. Rec.*

Pyogenic Origin of Rheumatism and the role of trauma in its Causation.

PHILIP KISSINGER's views still further complicate the already unsettled condition of the rheumatism question. It is now almost universally admitted that the disease must be infectious in its nature, but as yet apparently no organism for which the claim of specificity can be upheld has been isolated. On the other hand, instances are numerous in which pure cultures of various pus-producing cocci have been obtained from the blood or other fluids of rheumatic patients, and the author seeks to justify his belief that acute articular rheumatism is closely allied to pyæmia by the citation of a large number of such cases. With this idea as a basis, the frequent occurrence of rheumatic joint affections after injury is easily comprehensible, for the local damage produces the place of lessened resistance, which is all that is needed to permit the germs to invade the tissues. These may have already gained access to the system through some separate site of suppuration, an angina, etc., or may directly penetrate the injured skin in the neighborhood of the articulation.—*Volkman's klinische Vorträge.*

Pathogenesis of Acute Yellow Atrophy of the Liver.

N. T. BAIMAKOFF found in the liver of a patient who died from this disease diplococci which were situated among the red blood cells. They were stained blue by methylene blue, and were in groups of from five to ten, or twenty, or thirty. An aureole resembling a capsule was around them. They were found in every part of the organ. No success followed the attempt to cultivate diplococci taken from the blood during life, nor from blood taken after death from heart, liver, gall-bladder, spleen, and kidneys. Diplococci may possibly be the cause of acute yellow atrophy, which is an infectious disease in which the liver shows more degeneration than do the other organs.—*New York Med. Rec.*

Chemical Resources of the Body serving as Antidotes.

ALEXANDER ELLINGER understands under the term antidote used in this sense not alone the ability to render harmless a certain quantity of any poison which may have penetrated into the system, but the stopping of its toxic action after it has already reached the circulation. A consideration of the etiological investigations of recent years brings the conviction that a vastly greater proportion of diseases than is supposed is due to the action of poisons either directly introduced, produced by adventitious organisms which have gained access to the body, or originating within it as the result of anomalies of metabolism. The whole understanding of the processes by which the system is enabled to combat these substances is still shrouded in mystery, and the only direction in which it is possible to approach the subject is by studying first the chemical processes by which the coarser poisons, whose composition is well understood, are disposed of. These are neutralization, oxidation, reduction synthesis, and decomposition, but for the details of their application to specific reactions reference must be made to the original paper.—*New York Med. Rec.*

Vitality of Certain Pathogenic Micro-organisms in the Juices of the Organs of Healthy Animals.

ANDREA CIACCIO from experimentation concludes: (1) That in the extracts of organs kept at a temperature of 37°C. (98.6°F.) micro-organisms were able to develop; (2) that the juices of the brain, liver, heart, spleen, lungs, and muscles of guinea-pigs and sheep possess antibacterial properties quite independently of temperature; (3) muscular tissue in especial possesses bactericidal properties. The value of the administration of raw meat in certain affections is well known, as, for instance, in tuberculosis; (4) the addition of certain other substances to the extracted juices appears to influence their properties; for instance, dog's serum and sodium chloride increase their bactericidal powers.—*Rassegna Internazionale della Medicina Moderna.*

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Some Important "Ifs."

If you want to get well or to keep well, don't worry.

If you want to be happy and to make others happy, don't worry.

If you want to be plump and fresh, don't worry.

If you want things to go right with you and yours, don't worry.

If you wish to be a helpmate to your husband, don't worry.

If you wish to be a loving and loved mother, don't worry.

If you want a good appetite, don't worry.

If you wish to sleep well, don't worry.

Worry is the curse of Englishwomen. Instead of taking the blessings that a kind Father provides, and being happy and content, all are passed over, and they worry for what they have not.

* "Don't cross the bridge until you come to it" is a maxim that it would be well for all to bear in mind.

Live to-day, and, so far as troubles and anxieties are concerned, leave them to the future. "As thy day, so shall thy strength be."

Care of the Mouth.

PERHAPS no part of the body is so often neglected as the mouth; especially is this noticeable in the case of children. A mother, who will religiously bathe her child and keep its body sweet and clean, will often fail to clean its mouth. A new-born infant should have its mouth washed after each feeding; a soft cloth wet in a weak solution of boracic acid should be used for this purpose. If this were always done, we should rarely find a case of infantile sore mouth.

After the teeth come and the mouth is large enough, a small, soft brush should be used; the teeth and mouth should be thoroughly cleaned at least twice daily.

In illness, where sordes and mucous accumulate rapidly, and where the tongue and lips are parched and stiff, attention is needed every hour; the mouth should be kept moist, and the same treatment carried out through the night as through the day. Boracic acid solution, listerine, lemon-juice, glycerine, and distilled water are all refreshing and soften the tissues; where the lips are chapped or fissures appear, a lubricant of cold cream or sterilised vaseline should be applied. Where the gums are spongy or soft, and bleed readily, a few drops of tincture of myrrh added to pure water will help to harden them. Small squares of old linen or soft gauze should be used instead of a brush where one is ill or weak. These should be immediately burned after use.

Every part of the mouth should be cleansed—behind the wisdom teeth, the roof of the mouth, and under the tongue; lemon-juice and water will remove the fur from a thickly coated tongue. Where the teeth are sensitive, the water used should be slightly warm.—*South Cal. Practitioner.*

Arsenic in the Marsh Case.

EDWIN J. BARTLETT says:—The result of the *post-mortem* findings in the famous MARSH case is given as follows: The stomach was the seat of extensive necrosis of the mucosa, with a granular deposit and pigment in the mucosa, in its glands and in the blood-vessels. The liver contained a deposit of pigment about the intralobular vessels and a few areas of parenchymatous and interstitial hepatitis. The kidneys exhibited hyperplasia of some of the MALPIGHIAN bodies and slight interstitial connective-tissue growth in the medullary portion. The blood-vessels in these regions were congested.

In the lungs the alveolar walls were somewhat thickened, the walls of the bronchi also thickened and infiltrated with lymphoid cells, with some desquamation of the lining cells, and some of the blood-vessels were filled with blood. The lower lobes were congested, and their vessels greatly engorged with blood, with small and slight hemorrhages into some of the air vesicles. The chemic analysis made for the identification of the arsenic resulted as follows: Stated in milligrams of arsenous oxid, from the stomach mechanically, 31; from the intestine mechanically, 32.8; from the stomach chemically, 48; from the intestines chemically, 14.85; from the liver, 28.14; from the kidneys, 5.86; from the brain and core, 4.05; from the urine, .875; thus making a total of 165.075 or 2.64 grains. This did not include the arsenic from the stomach and intestine themselves, nor that distributed in the blood, muscles, and other tissues. Samples of bismuth subnitrate and copper arsenite used in the treatment of the case, as well as a fountain-syringe, which it was thought might have been used to administer the arsenic by injections, were examined. The quantity of copper arsenite given was too small to be considered, and the bismuth contained less than $\frac{1}{100}$ gr. arsenic to each $\frac{1}{2}$ gr. The syringe contained only the quantity found in other fountain syringes of the same make.—*Phil. Med. Jour.*

Communications to Physician in Bastardy Case.

THE prosecuting witness and the accused in a bastardy case disagreed as to the date that the first intercourse took place, whether July 15, or August 3. Finally, the latter proposed that witness be examined by a competent physician, and if the examination disclosed that her pregnancy was of not more than four months' duration, he would regard himself as the author of her trouble and the father of her unborn illegitimate child, and would marry her. This offer was finally accepted, and a reputable physician was agreed on to make the examination. The examination was made, and, in the judgment of the examining physician, it disclosed that the pregnancy was more than six months advanced. To this result of the examination the physician was permitted to testify on the trial. But he was not allowed to testify that during the examination the complaining witness stated to him that the first connection with accused took place, as stated by the accused, on August 3. And this, the Court of Appeals of Kansas holds, case of *Clark vs. State*, was error. The evidence was excluded on the theory that it was a confidential communication, and therefore incompetent. But a statute making a physician or surgeon incompetent to testify concerning any communication made to him by his patient with reference to any physical disease, or any knowledge obtained by a personal examination of such patient, the court holds, cannot be construed to cover such facts as disclosed in this case. The court emphasises that the physician was not present as the physician of the complaining witness. She was not his patient. The examination was not made for the purpose of treating her for any physical, or supposed physical, disease. She agreed and submitted to the examination for the sole purpose of satisfying the accused as to whether he was the father of the child. She knew that the result of the examination was to be made known to her parents and to the accused before she submitted to it. Under such circumstances, the court holds, statements made by her to the physician during the examination, as to when the first connection took place, could not be regarded as confidential.—*Jour. Amer. Med. Assoc.*

THERAPEUTICS & PHARMACOLOGY.

Relative Value of Certain Articles of Diet in the Treatment of Disease.

THERE is probably scarcely a reader of the *Therapeutic Gazette* who has not been taught by the perusal of text-books, or by the lectures of his medical teachers, that in the treatment of BRIGHT'S disease certain articles of diet must be rigidly avoided, and among these that the various red meats or albuminous foods are to be put aside as largely as possible. Further than this, he has been instructed that if any meats are to be allowed the patient he is to use by preference white meat, such as the meat of chicken in preference to dark meats or red meats, such as mutton and beef.

Personally, we have never been able to see why a patient should be allowed to have small quantities of eggs, and white meat of chicken, and yet should be denied things such as roast beef, beefsteak and mutton; and recently a number of articles have appeared in continental journals, in which the question has been raised as to whether there is sufficient chemical and physiological difference between dark and white meat to justify us in permitting the use of one and forbidding the other. As a matter of fact, there are no chemical data which justify the prohibition of red meats. Such data as exist seem to be founded upon the supposition that dark meat contains a larger proportion of nitrogenous extractive than does white meat. But this is not borne out by the analysis of the various foods that we are discussing. On the contrary, chemical analysis shows that the difference between them, so far as extractive is concerned, is very slight.

Among the papers which we have mentioned we may quote that of OFFER and ROSENQUIST, which was published in the *Berliner Klinische Wochenschrift* in the latter part of 1899. This careful analytical paper is also quoted in the *Scottish Medical and Surgical Journal* and gives accurate tables, which show that there is no support apparently for the theoretical difference between white and red flesh, and these authors do not believe that we are justified in excluding red meat from the diet not only of cases of BRIGHT'S disease, but from the diet of those who are gouty—that is, provided that we are willing to permit these patients to eat meat at all. It is true that their views have been strongly combated by no less a person than SENATOR, who believes in the old-fashioned custom of excluding red meat from the diet of patients suffering from chronic kidney disease and gout. Whatever may be the ultimate result of this discussion, we believe that there is one point which is not to be overlooked, namely, that some of these patients at least may be allowed small quantities of red meat sufficiently frequently to prevent them from becoming entirely disgusted with white meat, and also in sufficient frequency to prevent them from becoming restive and uncontrollable upon the diet which is ordered.

Finally, it is not to be forgotten that it is by no means necessary to employ skimmed milk as a drink and nutriment for these patients. Unskimmed milk, which contains a larger quantity of fat, is therefore far more nutritious, and is infinitely better for such patients if they can digest it, and most of the patients who can digest skimmed milk can digest ordinary good milk which has not been skimmed.

—*Therapeutic Gazette.*

Iodine Used Hypodermically in the Treatment of Pulmonary Tuberculosis.

ALFRED CARRO CROFTAN declares that iodine is peculiarly a drug against which different subjects show marked idiosyncrasies. The chief symptoms observed are emaciation, usually accompanied by profuse sweats, some pyrexia, and an accelerated pulse; a peculiar psychical depression develops a form of hypochondriasis ("anxietas"). In the light of our theoretical beliefs, the administration of iodine should act curatively in pulmonary tuberculosis. Accurate dosage is essential to the success of the plan of treatment that is being advocated; too large doses will certainly aggravate, too small doses will be inefficient. Iodine injections were tried only on carefully selected cases. Twenty-seven cases have so far been treated with good results; nineteen were cases of incipient tuberculosis with only circumscribed areas of infection in one or the other of both apices. The results obtained so far are not conclusive, they are only suggestive, although they now appear to be sufficiently striking to warrant an optimistic view. The sooner the disease is recognized and treatment begun, the better the prognosis. Iodine was employed in the form of the ten-per-cent. preparation, and the injections were made into the subcutaneous tissues between the skin and the muscle, preferably in the gluteal and interscapular regions. Beginning with one drop of iodine, which, to give the necessary bulk for hypodermic administration, was dissolved in half a drachm or so of sterilized oil, the injections were gradually increased, one drop being added to the dose each day. The dosage was regulated by the symptoms: as soon as an improvement became apparent, the dose exhibited at the time was continued for a period of thirty to sixty days. If the quantity at first acting beneficially seemed to grow insufficient, the dose was again increased drop by drop; more than sixty minims a day have so far never been given. The writer believes pulmonary tuberculosis in its incipency, before it has become a mixed infection, to be one of the most easily curable of bacterial diseases.—*Journal Amer. Med. Assoc.*

Correspondence.

SUBORDINATION OF I.M.S. OFFICERS TO THE INDIAN CIVIL SERVICE IN MEDICAL AFFAIRS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—I. M. S. in your issue of the 12th December 1900 has so clearly stated the reasons for the decline of the Indian Medical Service, that little more remains to be said; it will perhaps place the undesirableness of the I.M.S. as a career more pointedly before medical students if the system of medical work in districts is brought to their notice also.

An officer of the I. M. S., when placed in civil medical charge of a district, discovers for the first time that he is not considered by Government worthy of being treated with ordinary confidence and courtesy, such as he has hitherto considered his right; and he learns that he may not correspond, even on purely personal matters, with the Inspector-General of Civil Hospitals of his province, except through the Collector of his district. Why this extraordinary rule should exist, it is difficult to understand, except that it is desired to belittle one official of Government and exalt another at this expense; no useful purpose is served, and dissatisfaction results. In every possible way is the District Medical Officer reminded that he is a figure-head, and the Collector alone considered capable of forming a trustworthy opinion in purely medical matters, regarding which the Collector can have no opinion; he must be consulted, and his decision is practically final.

As an instance of the amusing length to which this practice is carried, I will cite an instance which occurred about two years ago.

The 1898 edition of the *British Pharmacopæia* had not then been issued to civil dispensaries, and the Inspector-General of Civil Hospitals, N.-W. P. and Oudh, directed Civil Surgeons to enquire from Chairmen of District Boards (Collectors and Deputy Commissioners) if they considered the issue necessary. What possible knowledge on this subject could the Chairmen possess? It was not a question for the provision of extra funds, as the purchases were made from funds already allotted for dispensary use.

It is ruled that the District Magistrate alone is to judge if the stomach and viscera in cases of poisoning are to be sent to the Chemical Examiner; in practice the Magistrate probably does not hear of the case till after the *post-mortem* has been made and the Civil Surgeon has kept or destroyed the viscera, as he considers necessary.

Cholera appears in the district, and again the Civil Surgeon may not depute a vaccinator to distribute medicine without previously obtaining the consent of the Collector. The above are examples of how work is hampered, for no conceivable reason except to preserve the *precious* *izzat* of the District Officer. The last-mentioned rule works disastrously for the people, as three, four or more days may elapse before a reply is received from the District Officer, who is often out shooting in some part of the district difficult of access, and the disease makes headway unchecked. Here, possibly, is a reason why no direct correspondence with the Inspector-General may take place; were this not prevented, irregularities due to the senseless rules enforced would speedily be brought to notice.

It is pretty generally recognised by those already serving Government that the interests of the Covenanted Civil Service are of paramount importance, and that all persons and things are to be subordinated to that object; but this is not so widely known in the schools at home, or recruits would not be forthcoming in the numbers now available.

Allowances are cut down in every other service, or it would not be possible to pay the Covenanted Civil Service as highly as it is now paid.

Years of scarcity, war and epidemic disease have impoverished Government, and the shears have been freely employed where the I. M. S. and other services are concerned, only the I. C. S. remains untouched.

There is a marked want of courtesy in the manner in which transfers are effected; no warning is given, and the first that one knows of one's transfer is the notification in the gazette. This entails unnecessary unrest, and one can never live in comfort lest a transfer should cause additional loss for want of time to dispose of property, etc.

There is little hope of any improvement in the prospects of the I. M. S., as apparently no desire exists on the part of Government to secure the best men for the service. So far as the services are concerned, Government and the Civil Service are synonymous terms, and many civilians would be pleased if they had no European Civil Surgeon; they would then be kings indeed when they could, without risk of contradiction, formulate their opinions on all possible questions, sanitary and medical.

The interests of all and sundry European and Native officials and non-officials are subordinated to the civilian in India, and men of education and talent, who can get a living out of India, should pause before embarking on an Indian career. The Civil Service have got a grip on India and its few remaining plumbs, and nothing short of a catastrophe will shake that grip. They are unpopular with the European services, as it is felt that other services are starved in their interests, and redress for injustice, when a civilian is the offender, is impracticable. Native officials are discontented, but their case is hopeless; they must submit; this is their country, and they must live in it, whether fairly or unfairly treated by the civilian. With a European, who may possibly be a candidate for the I. M. S., it is different; he can make a living in more desirable surroundings than he can in India.

The *Indian Medical Record* has fought hard for the I. M. S. to be thrown open to the graduates of Indian colleges, but with all its well-meant efforts it has not done half as much towards that end as has the undesirable civilian, so commonly met with now-a-days in Indian districts.

I may appear to have wandered somewhat from my subject, but this is not actually so; former writers have given some reasons why the I. M. S. is becoming an undesirable career. I have touched on matters outside their letters, as I consider the greatest evil that an Englishman has to endure in an Indian career is his undesirable relation to the covenanted Indian civilian; their privileged communications on any and every subject places other officials at a disadvantage nothing can remove; honest work, talent, loyal service, honesty, all melt before the privileged communication of a covenanted civilian.

This being so, why select a career in the I. M. S.

Yours, &c.,
ANOTHER I. M. S.

A WORD ABOUT THE RECENT OUTBREAK OF MALARIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—As a sequel to the heavy rains of the monsoon of 1900, which amounted to more than double the usual average rainfall in several parts of India, there has occurred a general malarial poisoning which, strange to say, has not yet disappeared, even though we are near mid-winter. The period succeeding the monsoon is usually characterised by an outbreak of malaria, but the present extraordinary severity of the disease is more marked when compared to a similar outbreak which followed the drought of 1877. There is little doubt the recent epidemic of malaria has outlived its predecessor; this may be due to an excessive saturation of the soil and consequent

breeding ground for the mosquitoes concerned in the disease. Unlike relapsing fever, it has not spared the well-to-do classes, and the total mortality has swelled considerably, amounting to 213·3 per 1,000 in some districts. One thing remarkable about the present outbreak of malarial fevers is that it has shown certain clinical peculiarities, which it is the object of this correspondence to get elucidated in your columns as far as possible.

Over and above the symptoms ordinarily met with in malarial fevers, one often finds the following:—

(1) There are no chills or rigors, and the fever does not correspond to the usual varieties of malarial fever, but it assumes the continued type.

(2) Ulcerative and gangrenous stomatitis with inflammation and bleeding from the gums, not as an independent affection, but developed during the course of the disease, are observed in several patients, even of the upper classes, and often prove fatal. The whole cheek becomes gangrenous, several of the teeth fall out, and this occurs chiefly among children.

(3) There are excessive nausea and vomiting, often without any appreciable enlargement of the liver, and jaundice comes on without any apparent cause. The icterus has been known to occur even among cases uncomplicated with nausea or vomiting, and is of the obstructive form with clayey stools; no gall-stones or worms have been detected in the stools, and the condition appears to be due to an inflammatory condition of the bile-duct.

(4) Epistaxis has been known to occur in several instances.

(5) The mental condition is depraved: there is melancholia with homicidal tendencies in a few.

(6) Parotid bubo has been developed during the progress of the case in several patients; it has been known to occur even among patients who had no ulceration of the mouth. The bubo is developed during the second or third week of the fever, there being no trace of it during the first week, and usually ends in suppuration and with a favourable prognosis.

(7) Some of the cases are of the *cerebro-spinal type*. The following is a case in point:—

S. J., a boy aged six years, was seen on the 19th of December 1900, and presented the following symptoms at the time of visit:—

Temperature 104°; pulse 120, of small volume, compressible; a furred and foul tongue; the neck thrown back as in opisthotonus, with inability to flex it or straighten it; an erect condition of the penis; pain in the back chiefly complained of on touching the spine; stupor; eyes half closed; pupils slightly contracted; inability to answer questions; urine passed freely, high-colored; sp. gr. 1017; no albumen; a clonic spasm of the extremities occurred from time to time; constipation; a herpiform eruption was developed later on, and was confined to the head, neck and back, partly seen on the extremities; ended in recovery after a fortnight. Total duration of illness 23 days, excluding the period of convalescence.

*From the variety of clinical phenomena above noted, it is clear that it is not malaria, pure and simple, that we have to deal with; but that the atmosphere is loaded with the germs of other diseases which complicate malaria and modify its usual symptoms.

By way of treatment, quinine, purgatives, a nourishing diet, plenty of fresh air, and scrupulous cleanliness so as to avoid all abominable cesspools likely to harbour the mischievous mosquito, appear to be the only measures possible under the circumstances. While explaining the exact causes of the symptoms above noted, can you suggest anything by way of treatment?

Yours, &c.,
"LANCET."

8th January, 1901.

COL. HENDLEY AND THE CHIEF MEDICAL OFFICER, E. B. S. RAILWAY.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—With reference to a paragraph attacking and abusing the Chief Medical Officer, E. B. S. Ry., for resenting Colonel HENDLEY's unnecessary interference, I beg permission to make a few remarks. Colonel HENDLEY spent all his service in N.-W. P. and Rajputana, and had no knowledge of, or experience in, Bengal. He held a fat appointment in Jaipur, viz., the Residency Surgeoncy, for many years. Residency Surgeoncies do not offer much field for gaining experience and improving professional knowledge. A Residency Surgeon spends most of his time in sports and amusements with the Native Princes and their residents, and thus act, more or less, as *mosahebs* and companions. That one of such men should be brought and placed at the head of a department in a large and important province like Bengal passes comprehension—more especially when there were senior and more experienced local men. Dr. HENDLEY is a lucky man, because he held a fat appointment for many years and then tumbles upon another fat appointment, from which he will retire with extra pension. But that does not give him any right or title to get an important prize appointment like the Inspector-Generalship of Civil Hospitals, Bengal. He had no experience of Bengal, and has, therefore, to trust to his Eurasian Head Assistant. I am afraid this arrangement of allowing the Eurasian (I beg Dr. WALLACE's pardon) Imperial Anglo-Indian Head Clerk to manage business obtains in other Provinces and Local Administrations, and needs looking after by Lord CURZON, who has cleared the Augean Stables of the Secretariats. That a common Eurasian clerk should be allowed to rule the Medical Department and to order about Civil and Military Medical Officers, Civil and Military Assistants, and the poor Civil Hospital Assistants, is a great scandal that requires looking after. A common clerk, exercising such powers, must be exposed to great temptations.

Now the Civil Medical Officer of the E. B. S. Railway is not the only man who complains of Dr. HENDLEY's unnecessary interference, but many District Civil Surgeons make the same complaint. Why should Government pitchfork such square men in round holes?

Dr. HENDLEY is not satisfied with unnecessary interference in his own department, but must rank as SAUL among the prophets. We see in the newspapers that he is to read a paper at the Church Conference on the morals of his young countrymen coming out to India. It is very good of him to be so solicitous of the morals of his young compatriots and GRIFFITHS—but a little more charity to the Indian people would be more consistent with his profession of the Christian faith. Many pious Europeans hate Indians and call them niggers; but they forget that CHRIST himself was an Asiatic and a coloured man.

Yours, &c.,
COLONEL, I. M. S.

(We consider Colonel Hendley thoroughly justified in his action. Dr. O. C. Bose is physically unfit for his post as O. M. O. Colonel Hendley has an able personal assistant in Mr. Price, but Mr. Price simply obeys orders, and he cannot be credited or discredited by what Colonel Hendley sees fit to do.—ED., I. M. R.)

TRADE NOTICE.

FREDERICK STEARNS & CO.,

MANUFACTURING PHARMACISTS, DETROIT, MICH., U. S. A.

THE subject for Messrs. Frederick Stearns & Co's. Calendar for 1901, a copy of which they have kindly sent us, is "Contentment"—a very lovely tinted picture of a monk in his glory. We venture the hope that they may be as well satisfied with the coming year's business as the monk evidently is with his surroundings. The picture is a faithful reproduction by the three-colour process of the original painting, and was done by their own printing department, in whose artistic work they feel a pardonable pride, which its merits undoubtedly justify.

The twentieth century dawns upon us with every prospect for increased pharmaceutical trade. Certainly opportunity is not lacking in India; it is now for each medical man interested in pharmaceutical work to determine whether or not those prospects shall become a reality.

It has been Frederick Stearns & Co's. good fortune to be of assistance in this way to some tens of thousands of druggists and chemists in all parts of the world during past years, and we would again remind Indian pharmacists that their services as Manufacturing Pharmacists, with more experience, better facilities and more highly perfected methods than ever before, are at their command.

We have just reason to recommend Messrs. Frederick Stearns & Co's. excellent claims to the medical profession in India.

Government Medical Gazettes.

PUNJAB.

Asst. Surgn. Parmanand, doing gen. duty at Mooltan, was apptd. as a tempy. measure to the ch. of the Rewari Dispy., Gurgaon Dist., from the 3rd Nov. 1900, during the absence of Asst. Surgn. Sodhi Karm Singh to attend the Septennial Prof. Exam. of Asst. Surgns. at Lahore.

On return from Lahore, Asst. Surgn. Sodhi Karm Singh relieved Asst. Surgn. Parmanand of the ch. of the Rewari Dispy., Gurgaon Dist., on the 8th Nov. 1900.

Hosp. Asst. Ghulam Haidar, doing gen. duty at Jhelum held ch. of the Gujrat Civil Hosp. during the absence of Asst. Surgn. Harbhagwan Das to attend the Septennial Prof. Exam. of Asst. Surgns. at Lahore.

On return of Asst. Surgn. Harbhagwan Das from Lahore, 1st Class Hosp. Asst. Ghulam Haidar reverted to gen. duty at Jhelum on the 12th Nov. 1900.

Hosp. Asst. Mir Kutab Ali, Bahadurgarh Dispy., Rohtak Dist. was placed in visiting ch. of the Sampla Dispy. in the same dist., in addition to his own duties, from the 22nd May 1900 to the 3rd Sep. 1900, during the absence on deputation of the permanent incumbent, Hosp. Asst. Tufail Muhammed, on famine duty in the dist.

The following Hosp. Assts. of the second class having passed the Septennial Prof. Exam. of Hosp. Assts. held on the 15th Oct. 1900 are promoted to the first class:—

Munshi Ram; Lok Nath; Ghulam Kadir.

The following Hosp. Assts. of the third class having passed the Septennial Prof. Exam. of Hosp. Assts. held on the 15th Oct. 1900 are promoted to the second class from that date:—

Ghulam Muhammed; Munshi Ram.

On relinquishing med. ch. of the Poor House, Hissar, 2nd Class Hosp. Asst. Gurmukh Rai was apptd. to the ch. of the Western Jumna Canal Dispy., Ottu, in the same dist. on the 1st Oct. 1900, relieving 1st Class Hosp. Asst. Mussaddi Mal, who was placed on gen. duty at Hissar from the 5th Oct. 1900.

N.-W. P. OUDH.

Capt. E. B. Steel, R.A.M.C., to the civil med. ch. of Roorkhee, in addn. to his mil. duties, from the 25th Nov. 1900, vice Lieut.-Col. D. O'Sullivan, R.A.M.C.

Lieut.-Col. Emerson, I.M.S., Civil Surgn., on return from furlough, to the Sitapur dist.

Lieut.-Col. A. R. W. Sedgfield, I.M.S., Offg. Civil Surgn., on return from leave, to Budaun.

The services of Lieut.-Col. A. R. W. Sedgfield, I.M.S., Offg. Civil Surgn., Budaun, are replaced at the disposal of the Govt. of India, Home Dept., with effect from the date on which he relinquishes ch. of his present duties.

Civil Asst. Surgn. Sarat Chandra Chakravarti, on being relieved of the off. ch. of the Sadr Dispy., Meerut, to reserve duty at the stn.

Offl. Asst. Surgn. Baij Nath Vias, on reserve duty at Lucknow, to the off. ch. of the Sadr Dispy., Fatehpur, as a tempy. measure.

Civil Asst. Surgn. Nripendra Chandra Mukerji, in ch. of Fatehpur Sadr Dispy., on return from priv. leave, to the ch. of the Sadr Dispy., Partabgarh.

Civil Asst. Surgn. Suriya Kumar Mukerji, from the ch. of the Sadr Dispy., Partabgarh, to that of the Sadr Dispy., Rae Bareilly.

Civil Asst. Surgn. Hari Gopal Chatterji, from the ch. of the Sadr Dispy., Rae Bareilly, to that of the Sadr Dispy., Fatehpur.

Civil Asst. Surgn. Nobin Chandra Chakravarti, on return from deputation to Dholpur, to be Lecturer on Practice of Medicine, Med. School, and in ch. of Thomason Hosp., Agra.

Civil Asst. Surgn. Rashid-ud-din, on being relieved of the off. ch. of the Balrampur Hosp., Lucknow, to the ch. of the Hussainabad Dispy., Lucknow.

The undermentioned Civil Hosp. Assts. of the Provn. Est. having passed their septennial exam. on the 15th Oct. 1900, are promoted to the next higher grade, from the dates mentioned against the name of each official:—

Basant Rae, Gulzari Lal, Kirpa Krishn, Tara Datt, Latif-ullah, 15th Oct. 1900; Pir Muhammad, Basir Ali, Jewan Sahai, 1st May 1900; Baijnath, 29th Sept. 1900.

Lieut.-Col. E. S. Brander, I.M.S., Civil Surgn., who has been recalled from leave, to the Farrukhabad dist.

Major C. Macdaggart, I.M.S. Offg. Insp.-Gen. of Prisons, N.-W. P. and Oudh, on being relieved, to be Supdt., Central Prison, Lucknow.

BURMA.

Hosp. Asst. Mon Mohun Datta relinquished ch. at the Police Hosp., Myitkyina, on the 11th Nov. 1900 and assumed ch. of escort duties at Myitkyina, on the 12th Nov. 1900.

Hosp. Asst. Mon Mohun Datta relinquished ch. of escort duties at Myitkyina on the 25th Nov. 1900, and assumed ch. at the Police Hosp., Myitkyina, on the 26th Nov. 1900.

Hosp. Asst. Mon Mohun Datta relinquished ch. at the Police Hosp., Myitkyina, on the 1st Dec. 1900, and assumed ch. of his duties with the Sima escort on the 2nd Dec. 1900.

Hosp. Asst. S. Muniratna Pillay relinquished ch. at the Police Hosp., Magwe, on the 23rd Nov. 1900, and assumed ch. at the Civil Dispy., Yenangyaung, Magwe dist., on the 27th Nov. 1900.

Hosp. Asst. Ibrahim Hussain, on transfer to the Chin Hills relinquished ch. at the Civil Hosp., Yenangyaung, Magwe dist., on the 27th Nov. 1900.

Hosp. Asst. Naung Tun E. assumed ch. of additional duties at the Police Hosp., Magwe, on the 23rd Nov. 1900.

Hosp. Asst. Salik Ram made over, and Hosp. Asst. G. Francis assumed, ch. of the Civil Hosp., Mingin, Upper Chinwind dist., on the 22nd Nov. 1900.

Hosp. Asst. Salik Ram assumed ch. at the Out-post Hosp., Kalewa, Upper Chinwind dist., on the 27th Nov. 1900.

Hosp. Asst. Maung Po Sain, on return from leave, assumed ch. at the Civil Hosp., Panagbyin, Upper Chinwind dist., on the 21st Nov. 1900.

Hosp. Asst. C. Abdulla relinquished ch. at the Civil Hosp., Panagbyin, Upper Chinwind dist., on the 21st Nov. 1900, and assumed ch. at the Police Hosp., Kindat, Upper Chinwind dist., on the 26th Nov. 1900.

ORIGINAL ARTICLES.

A CLINICAL LECTURE ON SYPHILITIC DISEASES OF THE TONGUE.*

BY CHRISTOPHER HEATH, F.R.C.S.,

Consulting Surgeon to University College Hospital, London.

GENTLEMEN,—We have had lately in the ward a remarkable case of gumma of the tongue, and I thought it would afford a good opportunity to say a few words to you concerning syphilitic diseases of the tongue, considering that cases of this description form a fair proportion of the affections you will have to treat in your practices.

• PRIMARY SYPHILIS OF THE TONGUE.

With regard to primary syphilitic disease or chancre of the tongue, I have first to say that it is a very rare thing. Personally, I do not remember to have seen an actual chancre of the tongue, but I can show you here, in a German book containing good illustrations, a picture of a tongue with a chancre upon it. A chancre of the tongue, like a chancre of the lip or chancre of the finger, does not present that remarkable hardness which a chancre on the genital organs does. It is very important to remember that, and when you see a patient with a sore upon the lip (and sores on the lip are more common than on the tongue), and notice that there is no induration of the sore, but that there has been very early and rapid enlargement of the lymphatic glands beneath the jaw, you may conclude, especially if the patient is a young person, that in all probability it is a chancre; the same thing applies to the tongue.

The way in which the tongue may be inoculated with the syphilitic virus may vary, and one can imagine abominable practices occurring in certain well-known cities, but I hope not in London, whereby actual inoculation of the tongue may take place. You must remember, however, that a person may get a chancre of the tongue or of the lip perfectly innocently, because there is no doubt, in the present day at any rate, that mucous tubercles in the mouth can produce a primary chancre in the mouth of another person. I wish to put this point strongly, because up to within recent times it has been denied; but no leading syphilographer now-a-days questions that syphilis is communicable by mucous tubercles. Since, then, these mucous tubercles are common in secondary syphilis, considering the careless habits people have of using cups and spoons and pipes after one another, it is not wonderful that from time to time a primary chancre occurs in the tongue. Primary chancre of the tongue must of course be treated like chancre elsewhere, that is to say with mercury.

SECONDARY AFFECTIONS OF THE TONGUE.

Referring to the evidence of constitutional syphilis, we happen to have here to-day a patient, who, as you see, has a well-marked secondary eruption. The man has evidently got secondary syphilis, and now, on putting out his tongue, you notice that he has a fissured tongue, and I have no doubt that at some period the site of these fissures was marked by mucous tubercles. I say so,

because I find that on turning his lip out a little at the corner, it will be seen that the lip and the tongue have mutually inoculated one another. It is common to find further back in the cheek patches of mucous tubercles, which are distinctly inoculated from the tongue to the cheek. These mucous tubercles are just the same "mucous plaques" as we call them that you find so commonly about the female genitals. We do not so often see mucous tubercles about the male genital organs, because in the male the skin is kept dry; but in the female, where there is moisture and probably some vaginal discharge, we very commonly get on the moist skin about the vulva and the anus mucous tubercles, of which I can show you a very good representation in this book.

Here, in this man, I now show you there is exactly the same condition of things about the mouth, that is to say, one moist surface with another moist surface constantly touching it, in a patient under the influence of the syphilitic poison, resulting in the development of mucous tubercles.

These mucous tubercles may, moreover, occur in children as the result of congenital syphilis—in children who exhibit other evidence of congenital syphilis, such as coppery patches about the buttocks and mucous tubercles about the anus. This is very important, because a child with mucous tubercles about the mouth may so easily infect a woman whose nipple it sucks, though it cannot infect its own mother, the mother having already syphilis in her system; this is known as "COLLES'S LAW."

Another symptom of constitutional syphilis about the tongue and mouth is the development of inflammation superficial in its character. With it we get very commonly a shedding of the superficial layers of the mucous membrane of the tongue, including the filiform papillae. I believe that condition is much more common than is supposed, but it is not often seen, for what we more commonly meet with is the condition seen when the patient comes complaining of a sore tongue, with a history of having put up with the soreness for some weeks. Here the appearance has become altered, and more commonly the bald patch is found which is so significant of secondary syphilis of the mucous membrane of the tongue and mouth. The patient may have gone through the first stage without its having been recognised, and as a result of that shedding of the epithelium, there is a certain amount of cicatricial tissue causing smoothness of the surface of the tongue, recognised as the characteristic "bald patch."

SYPHILITIC ULCERATION OF THE TONGUE.

We may have another condition following that—namely, inflammation going on to ulceration, and that may show itself in various ways. It generally is a multiple ulceration, making grooves in the side of the tongue, not affecting very much the dorsum, but involving fairly deeply the sides and tip of the organ. I send round an illustration; you will see fissuring of the tongue and some hypertrophy of its tissue. Here is a better illustration, which shows exceedingly well the appearance after the ulceration has healed, and we have there a certain amount of thickening; you will notice also the sulci or grooves which have been cut

* Delivered at the University College Hospital, and sent to the *Record* for publication.

into the tongue by the process of ulceration. That process may of course extend a good deal into the tissue of the tongue, and you occasionally find, as is shown here, a true glossitis or inflammation of the tongue due to the syphilitic poison. In the case of the woman whose tongue I lately removed, you may remember that I called attention more than once to the fact that behind the gumma there was an ulcerated surface due to syphilis, so that we had there the late secondary and the tertiary manifestations of the disease together. You may even have the tongue split down the middle by ulceration; it is rare, but it does occur now and again.

We have, then, this ulceration, and we may have, either with or after the ulceration, a very considerable amount of chronic thickening of the tongue—a thickening of perhaps only one side of the tongue, and of a very chronic character. This thickening of the tongue is apt to alarm a patient, who immediately begins to think that he is suffering from malignant disease. I have no plate here which shows it, but you can understand that where there is chronic inflammation there may be chronic thickening, and that one side of the tongue may feel hard and lose a good deal of its ordinary characteristics.

The treatment for all forms of secondary syphilis of the tongue I am quite sure is the same, and that treatment is the administration of mercury. There is no use whatsoever in attempting to treat secondary syphilis of the tongue with potassium iodide; you must give the patient mercury, and you must push the mercury not merely constitutionally, but locally, if you wish to make a complete cure. I am in the habit of using a mercurial mouth-wash, beginning with a strength of gr. $\frac{1}{4}$ of perchloride of mercury to the ounce, that is to say, about 1 in 2000, and this strength I gradually increase. My usual prescription is perchloride of mercury gr. $\frac{1}{4}$, with 2 drachms of honey made up to an ounce of water. I tell the patient to take a mouthful of this, and to have his watch out and see that he holds the wash in his mouth for five minutes by the watch, as five minutes is a longer time than people think. It is quite useless to merely tell a patient to use a mouth-wash; then he simply gargles a little and spits the lotion out, and that is of no use at all. The tongue must be "pickled," and if the patient takes his watch out and breathes through his nose, and holds the lotion in his mouth for five minutes two or three times a day, it is astonishing how these tongues improve. Mercury must be given to the patient at the same time internally, and there are many ways of giving it. I have myself come to the conclusion that there is no more satisfactory way of giving mercury than by inunction; that is to say, by rubbing it in over night when the patient is going to bed. The patient should rub the mercury into the inner part of the thighs or the front of the belly, beginning with half a drachm of the blue ointment and going on to a drachm. This rubbing may be continued for many nights together without producing irritation, but if that occurs, then the site of the rubbing should be shifted to the lower part of the abdomen. One great advantage of prescribing mercury in this manner is that it gets into the system very gradually, and that the patient is not affected in the month. The patient bears the drug better, and it is

a more satisfactory plan than giving mercury by the mouth. You must warn the patient that, though he may have a daily warm bath to cleanse himself, he should not use soap except once a week, when the ointment may be washed away. I generally recommend a man to wear pyjamas, and to wear the same pyjamas every night for a fortnight or three weeks, in that way scouring the entrance of mercury into the system without any inconvenience.

Most of you have heard that at Aix la Chapelle there is a system of treating syphilis which is certainly extremely valuable. That system is nothing more nor less than what I have been describing to you. The people at Aix la Chapelle make a great fuss about the value of the sulphur water and the sulphur baths in use there; these are certainly very pleasant, but they have no real bearing on the cure; it is the steady daily rubbing in of the mercury by the attendants which produces such marked effects. The course at Aix la Chapelle is for six weeks, and it is easy to get a patient here in his own house to rub for six weeks, and then perhaps he may leave it off for a month or so, and then resume for a time. With reasonable precautions against getting wet and taking cold, I have found no difficulty in this treatment being carried out.

It is very important that you should never salivate a patient; that is a thing of the past; to avoid salivation, it is the custom at Aix la Chapelle to use an alum mouth-wash. Every patient there carries about with him this mouth-wash, and he is continually rinsing out his mouth. I have no doubt that if a patient be treated in this systematic manner the most marked curative effects can be secured.

LATE SECONDARY OR EARLY TERTIARY ?

Now let me draw your attention to the fact that there are cases of syphilitic tongue on the borderland between the secondary and tertiary stages; I mean cases which are not actually gummatous, but which are instances of late ulceration, and these cases are satisfactorily treated in the way I have indicated. I have a drawing here, made as long ago as 1870, of the tongue of a man who was brought to me because it was thought that he had epithelioma. I did not think it was epithelioma, and on looking over his body found on his thigh a well-marked eruption which no one could possibly take for anything but syphilis. Under the influence of mercury that man's tongue got perfectly well, and I may add that there is no doubt that tongues have been removed before now for conditions which might have been cured by mercurial treatment. When I hear of a patient remaining well for years after removal of the tongue for epithelioma, I have my doubts as to the correctness of the diagnosis, and it is natural to do so in the case of patients surviving for many years such a deadly disease as epithelioma of the tongue.

TERTIARY SYPHILIS OF THE TONGUE.

We will now consider tertiary syphilis of the tongue, of which we have such a remarkable example in the case of the woman who came into the hospital early in October. She is a middle-aged woman, who had got what no one could doubt was a well-marked ulcerated

gumma of the tongue. She happened to come in at the time of the October examinations at the colleges, and I sent her down as one of the cases. I believe there was only one opinion expressed, and that was that it was a case of well-marked gumma of the tongue. This gumma, you will remember, was in the ulcerated condition; and you must bear in mind that before it was ulcerated there was a hard mass to be noticed, involving nearly the whole of the right side of the tongue, but in her case there was something more, for all through the tongue there were little nodules of syphilitic deposit. It was one of those cases of multiple gummata which are not commonly seen, the gummata spreading through the substance of the tongue. I ought to add that she had an enlarged gland under the chin. I thought myself that the state of irritation of her mouth was sufficient to account for that enlargement, and I did not at first consider that there was anything of a malignant character about the condition. I said at the time—incorrectly, however, as it turned out afterwards—that we should cure the case by full doses of potassium iodide and a mercurial mouth-wash. We began with moderate doses of potassium iodide, giving it combined with ammonia and bark. She was put upon 10-grain doses, and seemed to be improving, and then we increased the dose to 20 and finally to 30 gr.; but we noticed that she did not further improve. In consequence of a tendency to salivation, I was obliged to stop the mercurial mouth-wash, and give her a lotion containing myrrh. What I generally order is just sufficient tincture of myrrh poured into warm water to make it milky. After some little time I felt quite sure that if there was not an epitheliomatous condition present that there ought to be, because the patient did not improve. It was clear that it would be better for her to get rid of the tongue than to allow the organ to continue in that condition, and the patient herself was only too glad to consent. A fortnight ago, therefore, I took away the whole tongue, and you may remember that I had to put my clamp-forceps behind the circumvallate papillæ just in front of the epiglottis. On taking away this large tongue, it showed to the naked eye the pasty appearance in the red muscle which is so characteristic of gumma, and there were also present the small gummata scattered through the tongue which I have mentioned. I particularly said to Mr. CURTIS, the surgical registrar, that I hoped he would make a careful examination, because I was not at all satisfied that it was solely a gummatous condition; and eventually, quite at the back of the tongue, Mr. CURTIS found a very distinct mass of epithelioma, a small amount certainly, but distinctly epitheliomatous. A specimen has been placed under the microscope for you to see to-day, and you can recognise there what no one can doubt to be epithelioma.

It is clear, then, that this patient, having gone through a prolonged course of ulceration of the tongue, eventually developed epithelioma, and I am glad therefore that I have removed the entire tongue. I hope I have removed the whole of the disease; but though I went close to the epiglottis, I am afraid she will have further trouble in connection with the glands in the chin. You will remember that I very carefully scraped them out, and cleaned up the part generally; and we must hope for the best.

In connection with these cases of gumma of the tongue, which go on for a long time and develop epithelioma, I will quote to you a saying of Mr. JONATHAN HUTCHINSON: "If you irritate a part sufficiently long, you may grow epithelioma." As an example of this, take the irritation of a pipe continually affecting a lip, and ending in the development of epithelioma of the part, and this is a well-known fact clinically, for we hardly ever meet with epithelioma of the lip except in males who smoke. Given, therefore, any prolonged irritation, you have the probability that epithelioma will grow, and that is exactly what has happened in the case of this woman. It is this sort of case which is brought to you with a history that the patient has had a sore tongue, and has been under judicious medical care, with the result that, though the tongue has improved up to a certain point under potassium iodide, yet it has never got well. These cases of a double kind, if one may so call them, which have epithelioma grafted on to a gumma, may, and do, for a short time improve under the influence of potassium iodide, for no doubt the ordinary small-celled inflammatory exudation becomes absorbed, and things become improved for a time; but potassium iodide has no effect whatsoever on epithelioma, and the tumour goes on growing, eventually resulting in some operation having to be done if the patient's life is to be prolonged.

The treatment of a gummatous condition I have already indicated, full doses of potassium iodide with the addition, as a rule, of a mercurial mouth-wash. It is astonishing what a quantity of potassium iodide some of these patients will bear, taking sometimes 30 to 40 gr. three times a day, with the result that eventually a thorough healing may occur.

LEUKOPLAKIA.

There is one other thing I should like to say a few words about, and that is a disease of the tongue with which you are all familiar, which we call leukoplakia, and I put it last, because it is by no means always of syphilitic origin. Leukoplakia may occur entirely apart from syphilis, common cause being tobacco; but if a patient is not only the subject of syphilis, but also smokes tobacco, he is very likely to have a much worse tongue than if he were free from syphilis. Although I do not say that every case of leukoplakia is complicated with syphilis, as of course that would be incorrect, still I do say that many cases arise in conjunction with syphilis, the result partly of syphilis and partly of local irritation; and further, I believe that you must always have that local irritation present in order to produce leukoplakia.

WARTS.

In connection with the subject of my lecture, there is another thing I must mention, and that is the condition known as warts. I show you here a man with tertiary syphilis of the palate and throat, and the point I want you to note is that at the base of the tongue, quite at the back of the organ, there is a somewhat warty condition. That is not a very common thing, but the condition is one of the evidences of syphilis, and this case affords a good example of it. He is being treated for tertiary syphilis, and you will notice

that his face is scarred and that his palate is perforated. I am treating the warty portion of the tongue with nitrate of silver, and, if necessary, I shall try chromic acid, 10 grs. to the ounce. Another useful application is cyanide of mercury, 15 grs. to the ounce, brushed over the affected portion of the tongue. This often does wonders for this sort of thickening, and also for old chronic ulceration. It is necessary, of course, to be careful that the patient does not swallow any of the application.

I need hardly remind you that you must not confuse the syphilitic warts at the back of the tongue with the condition that sometimes is seen on a perfectly healthy tongue—I refer to the slight hypertrophy that may occur sometimes of one of the papillæ of the tongue. I lately saw a case of wart of this kind in a gentleman who had not the slightest trace of syphilis about him; it was merely a slight hypertrophy of one of the papillæ of the tongue, and the best treatment is to touch it with the acid nitrate of mercury.

NOTE ON THE MAL-TREATMENT OF MALARIAL FEVERS AND ITS CONSEQUENCES.

By BHODUN MOHUN SIRCAR, L.M.S.,
Calcutta.

THIS formidable scourge—malarial fever—which has caused the ruin of so many mofussil towns and villages of Bengal and other provinces, first made its appearance in Jessore some three quarters of a century ago, making a sad havoc in that flourishing town. Within our recollection, it next appeared in the districts of Burdwan, Hughly, Nuddea and the 24-Pergunnas in the latter end of the fifties, devastating most of their prospering towns and villages, many of which were once renowned as sanitariums in Bengal. Later on it spread to Rungpore, Rajshahi, Dinajpur and other districts.

Various theories have been advanced from time to time as to the causation of these fevers. Various means have also been adopted to improve the sanitary condition of these fever-stricken districts in the way of clearing the jungles, improving the streets and drains, providing tanks, wells and filtered waters, excavating canals in lieu of their natural watercourses, which had been obstructed by railway and other embankments, and deepening drainage channels silted up in course of time. But it is a matter of great regret that nothing, or very little, has been done, either by Government or the profession, in the way of providing or suggesting proper remedies to check the progress of the fever in its chronic stage, which is so complicated in its nature and fatal in its consequences.

Quinine is the only medicine which has been found useful in checking the fever, and is accordingly used very largely all over the country, both by the profession and the people, in the acute or primary stage of the disease, to check the fever and prevent its recurrence. But in the rural districts no regular or systematic treatment has been enjoined or followed in its chronic or secondary stage to check its progress and prevent the relapses which are so frequent in these fevers. This is due partly to the want of proper medical aid in villages, and partly to the

impoverished condition of the people, who can ill-afford to avail themselves of good medical treatment. This gave rise to the preparation of patent medicines, which could conveniently be used for days together without any doctor's advice. With few exceptions, quinine was made the staple ingredient of these medicines, combined with purgatives, iron and vegetable tonics. The large doses of quinine contained in them promptly checked the fever, and the patients being satisfied with the efficacy and cheapness of the medicines, largely availed of them. Thus, within a few years, various kinds of patent mixtures, pills and powders, supposed to have anti-malarial properties, came into existence and found a ready and extensive sale in the market all over the country.

In this way the injurious practice of mixing quinine, Epsom salt, iron and other ingredients all in one mixture, and allowing the same to be used in all stages of malarial fevers, both acute and chronic, has become very common, and is much to be deprecated. The difference in the physiological actions of these different drugs and their respective effects on the system in the different stages of the disease are altogether overlooked. Their indiscriminate use has thus given rise to serious consequences. In the acute stage of fever, with high temperature, iron acts as a poison—it suppresses the secretions, constipates the bowels, and brings on congestion of the liver, spleen, kidneys and other organs. But at the same time iron is one of the best tonics that we have in improving the blood and renovating the system when administered in the chronic stage, when there is little or no fever. In treating a case of fever, surely no qualified physician will prescribe iron in its hot stage, with thirst, scanty, high-coloured urine, constipation, foul tongue and the more or less irritated condition of other organs, nor until the fever has left and the patient has become convalescent. But in using these patent medicines, the patients are obliged to take iron along with quinine and its other ingredients from the beginning of the fever, irrespective of its injurious action in the hot stage or until it has left. On account of its repeated use in that condition in every relapse, which is so frequent, the liver and spleen become congested and enlarged, other organs become deranged, the condition of the patient becomes weak and anæmic, and anasarca, cachexia and other fatal symptoms gradually supervene, terminating in death. In the same way Epsom salt, or any other similar purgative which may do good in the first stage of the fever by clearing the bowels, but its unavoidable continuance for days together till the bottle is finished, gradually brings on diarrhoea, dysentery and other complications.

This empiric and heterogeneous combination of febrifuges, purgatives, hæmatics, bitter tonics, &c., cannot therefore but be wrong in principle, injurious in action, and fatal in its consequences. My long experience of malarial fevers in Bengal, extending over a period of nearly forty years, has convinced me of the undeniable fact that much of the sufferings of the victims of malaria in villages is largely, if not wholly, due to the continued and indiscriminate use of these patent medicines, which in a manner augment and perpetuate the evils. Those who suffer most in this way are generally

the poor and ignorant villagers living in rural districts. In their eagerness and anxiety to get rid of the fever, they buy a patent medicine which sells largely in the village, and after using it for three or four days, the fever subsides or altogether disappears, and they are delighted at the wonderful efficacy of the medicine, not knowing what baneful effects will subsequently follow from the poisonous action of iron and other contraindicated drugs which they have swallowed along with the quinine which has checked the fever. Being relieved of the fever, they resume their work, and after two or three weeks get a relapse, when they again take the same medicine: the fever subsides in three or four days as before, and they go to work again, each time in a more exhausted condition than before. As a rule, a few relapses yield to the same treatment. In this way, suffering from frequent relapses and using large doses of quinine and iron every time in the course of high fever, they become more and more weak and enervated; the liver and spleen become enlarged, emaciation follows, dropsy supervenes, vital power comes down to its lowest ebb, and they are reduced to the living skeletons so frequently to be seen in fever-stricken districts.

It is generally believed that enlargements of the spleen, which are so much noticeable in their various stages of being slightly, moderately and excessively enlarged among the poor population of malarial districts, are caused by frequent relapses of the fever, and I may unhesitatingly add that the repeated and indiscriminate use of iron and other injurious ingredients in all stages of the fever is another potent factor in enlarging these organs and gradually leading to fatal consequences. Observation has also proved that the percentage of enlarged spleen in the riparian districts is far above than the percentage found in inland districts, and the reason of it is not far to seek. It is the poor and ignorant villagers residing in the more unhealthy out-lying rural tracts that largely consume these patent medicine, and are consequently the greatest sufferers with enlarged spleen and liver.

The use of these patent medicines has unfortunately become so popular that, notwithstanding all this mischief of human suffering and death which has been going on for the last forty years, the voice of reason has never been raised to question its righteousness. However palpable the cause may be, perhaps it would be blasphemy for any one to attribute the evil to these favoured bottles, pills or powders, which have such a magnetic charm over the poor and ignorant sufferers.

I cannot be too strong in my assertion that the effects of these patent medicines are far more formidable and injurious, and less amenable to treatment, than those of the malarial poison itself. It is far more difficult and hopeless to cure diseases with complicated symptoms brought on by mal administration of medicines than in their simple state.

With the few exceptions of patent medicines professed to be made up of indigenous vegetable drugs, the bulk of them are prepared with the same medicines which are recommended and used in our therapeutics for the treatment of malarial fevers. But the mischief lies

in the injurious practice of mixing all of them in one mixture and using the same as a panacea in all stages of the disease, irrespective of the conditions in which each of the medicine is indicated.

Such is the insidious way in which these patent medicines are sapping the vitality of the fever-stricken people of this country, augmenting their sufferings and hastening their death. I think it is high time that the public attention should be called to this lamentable state of things, with a view to bring about a change in the policy, principle of preparation, and the mode of administration of these medicines. The first and simple improvement suggested would be to separate the medicines according to their respective modes of action, instead of combining all in one mixture; and secondly, to administer them separately, according to their indications in the different stages of the disease. Such an innovation on approved principles will be a boon to the country, and every effort should be made and encouragement given to its adoption.

It may be news to the general public that these patent medicines, instead of curing these fevers, have been aggravating their symptoms, bringing on serious complications and causing death after prolonged suffering. But it is a matter of great regret that such widespread practice has escaped the attention of the profession, and especially of responsible medical authorities, who have made malarial fever a subject of their special study and enquiry. One word from them in time would have nipped the evil in the bud and saved the sufferers and lives of thousands and thousands of the fever-stricken people. However, it is a hopeful sign that the more intelligent portion of these sufferers from their practical experience are fast losing their faith in these medicines. Be that as it may, and however strong the current of popular opinion may be in favour of these patent medicines, I feel very strongly in the matter, and deem it my duty to express my views on the subject for the benefit of suffering humanity, and risk the courage of my conviction without any fear of contradiction.

With these few remarks, I leave the matter in the hands of the profession and the sanitary officers for proper investigation, and to find out means to check this evil practice.

ABSTRACT OF A CLINICAL LECTURE ON RECURRENT APPENDICITIS, WITH REMARKS ON A SERIES OF FIFTY CASES TREATED BY OPERATION.*

BY F. A. SOUTHAM, M.B., OXON., F.R.C.S.,
Surgeon to the Manchester Royal Infirmary; Professor of Clinical Surgery, Owen's College, Manchester.

THE causation and symptoms of recurrent appendicitis, and its treatment by removal of the appendix, having been described, the following reference was made to a series of fifty operations which had recently been completed for this affection, as the conditions met with in the cases so treated served to illustrate many of the points to which attention had been directed.

* Delivered at the Manchester Royal Infirmary, and sent to the Record for publication.

CONDITION OF APPENDIX.

In almost every case the walls of the appendix were thickened, and at some point in its course the lumen was either partially or completely occluded. On the distal side of the obstruction the tube was frequently found to be dilated, and distended with fluid, which in most cases was of a mucopurulent nature, but in a few instances clear and watery or consisting of pure pus. In some cases the appendix was quite straight, in others twisted or sharply bent on itself, occasionally at such an acute angle that its tip was almost in contact with its caecal extremity.

OCCURRENCE OF SUPPURATION.

In fifteen cases suppuration had occurred in the neighbourhood of the appendix. In twelve instances a localised abscess was present, often of small size—for example, not containing more than half a teaspoonful of pus. In other cases there was no distinct collection of pus, but small caseous deposits, evidently the inspissated remains of former abscesses, of which the fluid portion had become absorbed. In three instances the suppuration was diffuse, there being well-marked evidences of general purulent peritonitis when the patients came under observation.

This fact—namely, the frequent occurrence of suppuration in recurrent appendicitis—should be borne in mind in the treatment of this affection, for it is a strong argument in favour of operative interference. Though in the majority of cases the attacks subside time after time without any formation of pus, yet there is always a great risk of this complication occurring, and it would appear that a repetition of the attacks is no safeguard against it. In most of the cases where an abscess had formed the attacks had been frequent, and in each of the three patients, where the suppuration was diffuse, they had been so numerous that the patients had lost count of them.

The formation of pus was usually found to be associated with a perforation of the appendix, and was therefore probably excited by an escape of its contents. In one case the abscess presented in a very unusual situation—namely, on the anterior wall of the rectum—the first symptom indicating its existence being a sudden attack of retention of urine. The abscess was tapped and drained *per rectum* with a satisfactory result, and the patient, a male, made a good recovery.

FÆCAL CONCRETIONS.

In seven cases faecal concretions were found to be present; in five the concretion was lying inside the appendix; in two it was outside, having perforated the walls of the process and excited suppuration round it.

FOREIGN BODY.

In only one instance was a true foreign body present, and this was a pin which was found in an abscess cavity in close proximity to the appendix. The pin had probably been lodged in the appendix for some time, and then ulcerated through its walls, for the process was surrounded by adhesions and almost obliterated. The head of the pin was encrusted with a considerable deposit of calcareous matter.

ADHESIONS.

In the majority of cases adhesions were present, in some instances so slight as to cause no trouble, in others so extensive and so dense that considerable difficulty was experienced, first in recognising, and afterwards in liberating and removing the appendix. Their presence or absence bore no relation to the number or severity of the attacks, and it was impossible to say before the operation whether or not they would be encountered. For example, there was not a trace of an adhesion met

with in one patient who had suffered from about twenty well-marked attacks, while in others, after only two or three slight attacks, they were found to be so extensive as to render the operation extremely difficult. It was noticed that when a local thickening or induration could be felt during the quiescent period following an attack, adhesions were always present; but the absence of this sign could not be taken as an indication that they did not exist, for the appendix was often found lying behind the caecum with its tip directed backwards, fixed and buried in a mass of adhesions which it was impossible to recognise previous to operation, and not even after the abdomen was opened until the overlying caecum had been drawn forwards and upwards out of the way.

A complication occasionally met with as the result of former attacks of appendicitis is intestinal obstruction from inclusion and compression of a coil of bowel in, a mass of old adhesions. Several cases of this kind (not included in this series) have come under my observation, where a median laparotomy was performed for the relief of the obstruction, and where the intestine was found so tightly constricted and bound down that its liberation was a matter of considerable difficulty.

NUMBER OF ATTACKS AND THEIR BEARING ON THE QUESTION OF OPERATIVE INTERFERENCE.

In forty cases the patients had suffered from three or more attacks, and in thirteen instances the attacks had been so frequent—often ten or twelve, and sometimes even more numerous—that no count of them had been kept. In five cases there had been only one distinct attack, the operation being performed, as pain, tenderness, and a localised thickening persisted for some time after the subsidence of all the acute symptoms. In one of these the appendix contained a hard faecal concretion; in two it was completely stenosed and dilated beyond; in the remaining two it was bent and bound down by adhesions, so that there would undoubtedly have been a recurrence of the attacks in each instance if it had not been removed. The persistence, therefore, for some weeks or months of a tender swelling or thickening in the situation of the appendix, especially if accompanied by rigidity of the overlying muscles and a varying degree of pain, may be regarded as an indication for operative interference, even when a patient has suffered only from a single attack of appendicitis. In the absence of these symptoms, I should not advocate operation after a first attack, for it is a well-recognised fact that a patient may suffer from a single attack and have no recurrence. The probability of the attack recurring is variously estimated at from 23 to 44 per cent. of all cases. When, however, a patient has suffered from a second attack, operation should be advised, even in the absence of any local symptoms during the quiescent periods, for after a second attack more are almost certain to follow.

DURATION OF SYMPTOMS.

The length of time during which the patients had suffered from the attacks varied from several months to six years.

SEX.

Of the fifty patients, thirty-five were males and fifteen were females, it being generally found that the former sex are the most liable to this affection.

AGE.

As regards the age of the patients, more than one-half of the cases—namely twenty-nine—were met with in persons between 20 and 30 years old, twelve occurred in persons between 10 and 20, seven between 30 and 40, and two between 40 and 50; so that after 30 years of age the tendency to this affection diminishes as life advances. Its more frequent occurrence in young subjects is probably due to the fact—as KELYNACK has pointed out—that more lymphoid tissue is present in the wall of the appendix in the young than at a more advanced age, and the tendency for this structure to become the seat of inflammatory processes in early life is well recognised.

† In fourteen cases operated upon since the completion of the above series, a local abscess was found in three instances. This gives a total of sixty-four cases, in eighteen of which suppuration had taken place—that is, in 28 per cent.

A MIRROR OF PRACTICE.

A FATAL CASE OF TRAUMATIC TETANUS TREATED WITH ANTITETANUS SERUM.

BY CAPTAIN E. C. HAYES, R. A. M. C.,

Barrackpore Military Hospital, Lower Bengal.

THE treatment of tetanus by antitetanus serum is as yet on its trial, and this explains the publication of the following case :—

G. W., R. G. Artillery, was admitted into hospital on June 6th, 1900, with a severe burn of the right hand. The back only of the hand was involved, and its outer palm was mostly affected. The whole of the posterior surface of the four fingers was severely charred; the bone of the first phalanx was wholly exposed, as well as half that of the second phalanx, and the joint disorganised; the middle phalangeal joint of the third finger was also opened, and the extensor tendon was in view for about $2\frac{1}{2}$ inches of its length. The history of the case was that while working at a forge the patient had been overcome by the excessive heat, had fainted, and his hand had come in contact with the fire. The usual caron oil treatment was at once applied, and the patient transferred to hospital, where opium and stimulants with quinine were administered. There was, needless to say, considerable shock.

All went favourably up to June 14th (the ninth day), when the sloughs, which were very extensive, began to separate. On the morning of June 15th the patient complained of being unable to open his mouth freely. Examination revealed the fact that his masseter and sterno-mastoid muscles were abnormally tense and rigid. The onset of tetanus was at once suspected. The patient was seen in consultation with Major R. R. H. MOORE, R. A. M. C. The question of amputation at the wrist was dismissed, as it was hoped to remove the toxin-producing focus by a less radical measure, especially as the thumb, forefinger, and middle digit at any rate were expected to recover. It was therefore determined to use almost continuously the hand-bath with a warm solution of 1 in 1000 corrosive sublimate, plus five parts of tartaric acid, as recommended by SAHLI and endorsed by ROSE, of Zurich—a solution which KITASATO states kills tetanus spores in thirty minutes. The special stimulating fluid dietary on which the patient had been placed was continued, and isolation in a quiet dark room adopted. Antitetanus serum was sent for, and in the meantime hypodermic injections of a 1 per cent. solution of carbolic acid, as recommended by ROSE, were given in five minim doses every three hours, combined with the exhibition of chloral hydrate grs. xv at once, and grs. x every two hours afterwards.

In the evening the patient remained in much the same condition. He was sweating, as is usual, very freely; but said his "mouth was better a trifle." He had received all four hypodermic injections of carbolic acid, and the chloral had produced no drowsiness. His condition next morning was somewhat worse. The rigidity of the sterno-mastoids had increased, and he had had during the night four severe attacks of spasm, involving the chest

and abdominal muscles, and presumably also the diaphragm. Sweating was profuse. His speech was still fairly clear. The hand-bath had loosened the sloughs, and more were removed with forceps. The wound had commenced to granulate at the edges. The fingers were then separated by plugs of cotton wool, and immersion continued all day. Carbolic lotion was substituted for the corrosive temporarily as a preventive measure against absorption of the latter. The chloral was stopped and a more vigorous sedative régime instituted—that is, $\frac{1}{2}$ gr. of acetate of morphine was given hypodermically every three hours. This was continued all day. His temperature at 4 P.M. was 99.4° , and his pulse 98, full and strong. Spasms were more severe and easily excited, while the patient had obtained no sleep, notwithstanding the morphine administered. At 5 P.M. the required antitetanus arrived from Messrs. SMITH, STANISTRETT, and Co., of Calcutta. They supplied it in the dried state, as prepared by the Jenner Institute of Preventive Medicine; dose one to two grams. The fluid serum was prepared from this, and $1\frac{1}{2}$ gram was hypodermically injected at once. The morphine was neither lessened nor discontinued. Through the night the hand-bath was used.

On the following morning, June 17th, no change for the better had taken place. He appeared worse; had several severe spasms during the night, which were easily provoked. By the morning his temperature had risen to 103° , respirations 22 per minute, pulse 98 per minute, full and strong. Specific gravity of urine 1030. No albumen or sugar. There appeared to be less rigidity of the masseters and sterno-mastoids, but the recti abdominales were severely affected, and, with the onset of a spasm, emprosthotonos, though not very marked, appeared. A further $1\frac{1}{2}$ gram of the above antitetanus was then hypodermically injected at 10 A.M. The patient was left in the same state, and had no appearance of any impending danger. Spasms continued every quarter hour, as on the day before, and the pulse was full and strong, nevertheless the patient died suddenly in a spasm, of no severe character, quite unexpectedly at 2.5 P.M. Death was due presumably to spasm of either the heart or respiratory muscles.

Necropsy.—The brain was found to be highly congested, especially the superficial veins; the fourth and two lateral ventricles shared in the same condition; through the white matter minute points of congestion were present. The cord was in a similar state. The musculo-spiral and posterior interosseous nerves of the wounded arm were exposed, but no vascularity was found, though they had a pale yellowish and parchment-like appearance. The blood vessels were full of dark fluid blood.

Remarks.—Taking ROSE's definition of a severe case of tetanus as one occurring within ten days of the injury, this case must be regarded as moderately severe, though the clinical symptoms of its onset were comparatively mild. OSLER remarks on this head that favourable indications are late onset of the attack, localisation of the spasms to the muscles of the neck and jaw, and absence of fever; from which also it must be concluded that the above case was of a medium degree of severity. If so, a favourable result would have been anticipated from the exhibition of antitetanus. It certainly was most

disappointing in its results, particularly because I was biased in its favour by the 68 per cent. of recoveries among cases collected by GOODRICH, which compares more than favourably with the pre-antitetanus serum day fatal percentage of 85 to 90. It may be fairly remarked as a contrast to these figures of GOODRICH that KANTHACK showed from collected cases treated with the most universally praised antitetanus, that of TIZZONI, the comparatively low figure of 25.8%. The evidence of one recorded case must of course be taken with that from others in attempting to answer an apparently unsatisfied question.

RUPTURE OF KIDNEY AND SPLEEN.

BY LIEUT.-COLONEL W. A. GARDINER L. R. C. P. I.,
R. A. M. C. (RETIRED.)

Military Station Hospital, Ipswich.

*BOMBARDIER J. P., aged 40, a Royal Reserve man, had served in India twelve years, took his discharge, and was called up last March. He was rough-rider to his Battery of Royal Field Artillery. He was a stout, somewhat florid man, in good health. On October 29th he was riding a remount in the barrack square, when his horse shied, and then bucked, throwing him heavily. He was, he said, riding at a walk, and loosely in his saddle, which accounts for the heavy fall.

He was at once brought to hospital, walking part of the way with help. I was in the barracks, and saw him a few minutes after the accident. He complained of severe pain in the left loin, extending across the abdomen; he was perfectly conscious and clear in his statements. He said he was not kicked, that, as far as he could tell, "he fell in a heap" on the left side, but more or less doubled up.

I found no external injury, no broken ribs, no injury to the head or spine, and no contusion of the abdomen. The severe pain continued all day. He was admitted about 11 A.M., and died at 7.30 P.M. During the day he passed two or three times a small quantity of blood from the bladder.

A post-mortem examination was made thirty-nine hours after death. In this I was fortunate in having the assistance of Dr. GEORGE ELLISTON, M.O.H., Ipswich. The head was not examined. There was no mark of injury on the body except two trivial abrasions—one on the left cheek, and one on the point of the left shoulder. There was no evidence of any injury to the abdominal parietes. The body was that of a well-fed, healthy, strong man, probably weighing about 13 stone. The lungs were normal, with the exception of old adhesions on the left side. The heart, loaded with fat externally, was otherwise normal; the valves were healthy, its weight 1 lb., 7 ozs. The stomach was empty and quite healthy; the liver was healthy, weight 3 lbs. 14 ozs. The right kidney was normal, 6½ ozs; the left kidney and the spleen were embedded in a mass of coagulated blood, which occupied nearly the whole of the left side of the abdomen. The capsule of the kidney was ruptured, and the kidney was torn across into nearly equal separate halves—weight 8 ozs. The spleen also was

ruptured at its lower end; the part torn was not, however, like the kidney, detached. The hæmorrhage appeared to have taken place chiefly from the splenic vessels. The intestines and bladder were normal. This very grave injury, arising in so simple a manner, can be only partly explained by the severity of the fall. Probably muscular contractions at the moment helped, but it is a well-known fact that a complete fall from horse-back at the moment when the rider is sitting loosely at a walk is likely to be worse than when going at speed and with a tight seat.

RAPID CURE OF POPLITEAL ANEURISM BY ACUTE FLEXION.

BY LIEUTENANT-COLONEL H. R. WHITEHEAD, F.R.C.S.,
ENG., R. A. M. C.

Station Hospital, Murree, India.

PRIVATE J. S., Queen's Regiment, was admitted to the Station Hospital, Murree, with the following history: He first felt pain in the right popliteal space in middle of June 1900. He was doing gymnastics, and after jumping the horse he suddenly felt pain behind the right knee. He continued at his duty for about a fortnight, and did not notice any pulsation, but the leg was swollen and painful. He reported sick at the Station Hospital, Kuldanea, on July 4th, and it was then discovered by the medical officer in charge that an aneurism of the popliteal artery was present. He was treated by elevation and flexion of the right leg and low diet, and a great deal of the swelling disappeared. He was transferred to the Station Hospital, Murree, on July 15th. A very distinct fusiform tumour was then present in the right popliteal space; it was about the size of a pigeon's egg and pulsated. The pulsation was expansile and synchronous with that of the femoral artery. The case was evidently one of fusiform aneurism of the popliteal artery. Only slight pressure symptoms were present, and the man was in good health. He had had syphilis in 1896, and was rather intemperate in his habits; but otherwise had a good history.

Before proceeding to any operative measures, it was decided to try the effect of flexion of the limb. On July 18th I flexed the right leg on the thigh, and the thigh on the abdomen, and secured the limb in this position with bandages. After half an hour the pain was so severe that I had to relax the bandages somewhat, and at the end of an hour the pain was still great, and I discontinued the flexion. On relaxation of the flexion the tumour was still pulsating. The next morning nearly all pulsation had stopped. It could only be feebly felt. There is no coldness of the leg or foot, but the aneurismal sac was very tender. The next day pulsation had completely stopped, and from that date to the present time (August 20th) had not recurred.

He had no coldness of the foot or extremity, and the collateral circulation was perfectly established. The tumour had consolidated and contracted, and could now be felt as a solid tumour in the ham.

The case is a remarkable one in the rapidity of the cure and the easy way it was effected.

AN UNUSUAL CASE OF IODOFORM POISONING.

BY HENRY M. EUSTACE, M. D.,
Dublin.

E. W., aged 35, although partially demented, was physically healthy, with the exception of a small superficial sore on the right ear.

On July 21st, at 11 a.m., I applied a dressing of iodoform gauze, two layers thick and 1 inch square, to this sore on the ear.

On the morning of the 22nd the nurse in charge of the case found the patient in bed, and the extremities very cold, the face anxious, the breathing normal, with the pulse poor. She soon became very restless, micturated involuntarily, and delirium of a muttering type was present. No erythema was visible, and no sample of urine could be obtained.

The pulp of chewed-up wood-wool and iodoform gauze was found in her bed; and she had evidently sucked the dressing during the night, and stated she had done so. She was given an emetic of mustard and water, which acted promptly. Hot-water bottles were then applied to the extremities, and the patient rallied, and drank hot milk. At noon on the 22nd the patient was given some nourishment, but vomited immediately, and complained of pain in the abdomen, and again collapse threatened. She was able to retain hot coffee, and, with the exception of a rise of temperature to 102.4° F. that evening, she recovered without further symptoms of poisoning, and was up on July 23rd.

The amount of iodoform in such a dressing must have been very small, but the patient must have been peculiarly susceptible to the drug. Dr. Fox has reported a case of iodoform poisoning by smell only, but in all other reported cases that I can find, the drug has been absorbed from the dressing through a raw surface, and therefore I venture to report this case in which the drug was taken directly into the stomach.

A CASE OF FRACTURE OF NECK OF FEMUR RESULTING IN ABSCESS, SEPTICÆMIA AND DEATH.

By THOS. H. BONNAR,

*Military Assistant Surgeon: Medical Officer in Charge
Plague Camp, Chouva.*

K. SINGH was a Punjabi Sikh lad of fairly good physique, but wanted. He was admitted with a diffuse swelling of the upper part of the right thigh, red and tense, with pain and hardness chiefly on the lower surface of the thigh. Right inguinal glands more prominent than left: tongue coated: bowels constipated obstinately: temperature normal in morning, with evening rise to about 100°: features drawn: inability to sleep. He gave no history of injury, but an abscess was suspected, the cause of which was not clear. There was no external injury noticeable. His leg was flexed and slightly turned inwards, which was attributed to the tension of the upper thigh. After a day or two the patient became restless and wandering, making attempts to leave his cot. The delirium became gradually worse: subsultus tendineus and picking of bedclothes: tongue dry and brown coated: pulse small and frequent: ammoniacal odour. Drowsiness and coma set in, which continued till he sank and died.

At the autopsy the internal organs were found healthy. On dissecting the muscles in the position of SCARPA's triangle, and also the superficial muscles at back of right thigh, nothing was discovered, except a serous exudation from the oedematous tissues. Femoral glands were normal: the psoas muscle on that side was found free, so also the iliac muscle, but in dividing the gluteus maximus and plunging the scalpel into the muscles, it reached to back of thigh, about 8 ounces of pus, and slightly offensive, welled out—the situation led to the head of the bone. On inserting the finger there was a jagged fracture of neck of femur (above trochanter); the bone here was rough to the finger and devoid of covering.

Indian Medical Record.

23rd January 1901.

I. M. S. MEN IN PRIVATE PRACTICE. ITS LIMITATIONS BY GOVERNMENT ORDERS.

QUITE recently we commented on the subject of men of the Indian Medical Service being allowed by Government to engage in unrestricted general practice in large cities. It may be as well to quote the official pronouncement on this matter. The following quotation is an excerpt from "THE REPORT OF THE MEDICAL COMMISSION OF 1878," appointed to enquire into the expenditure and administration of public hospitals in Calcutta:—

Resolutions gazetted by the Bengal Government.—
"XVIII.—That, subject to the fullest responsibility for the administrative and professional control of the institution under their charge, medical officers, who are at present allowed to take *private practice*, shall continue free to do so, provided it does not interfere with their public duties.

"The Committee consider that *private practice* has had much to do with the irregularities mentioned, inasmuch as the time of the officers concerned has been so occupied as to make them trust too much to their subordinates. They consider, however, that it is impossible to abolish the privilege without increasing the pay of the appointments. These are at present the chief prizes of the Service, but they are so in virtue of the privilege, and the mere pay attached to them is quite inadequate, when regard is had to the expense of living in Calcutta, to secure the services of the class of men required to hold them. They think, too, that the interests of the public are entitled to consideration, and that the experience of officers holding important hospital appointments should be available to the community, and that, if Resolutions XIV and XVIII are accepted, the interests of Government will be sufficiently guarded. A certain limited class of officers—Resident Surgeons, the Health Officer of the Port, the Principal of the Medical College, &c.—are forbidden to practice. The pay of resident medical officers was raised on the express ground that they were to abstain from practice, and that of the Principal is Rs. 550 a month higher than the maximum pay of a professorship, and all three have rent-free residences. The Rule (B. ii) has been so far relaxed as to allow the Principal to engage in consultation practice, and for this the Committee think there are reasons of public advantage. The principle on which the relaxation was allowed is held by the resident medical officers at the College Hospital to allow them the same privilege, but the Committee think that this position is indefensible. It is contrary to the nature and intention of a resident surgeoncy that the incumbent should engage in practice outside the institution. The rules of Government in this respect have not been strictly observed, and the Committee think—

"XIX.—That the rule forbidding certain officers to engage in private practice should be enforced, and should apply to native as well as to European resident officers.

"The resident medical officers at the Medical College Hospital are at present *Professors of Pathology and Physiology*. In the opinion of the Committee the two professorships should be *full professorships held by independent teachers*; and the resident medical officers, holding, as they do, a subordinate position to the hospital staff, should, as a rule, be junior men, and should hold their appointments for a limited period—*not more than two years*—as originally laid down for the resident surgeon in Government Order No. 370 of 1867. The experience acquired in this period as resident medical officer to a great hospital is so valuable, that as many officers as possible should, in the interests of the State, have the advantage of it. *The same remark applies to the Resident Surgeons to the General Hospital* without attached duties. The Second Resident has charge of the Presidency Jail in addition to his hospital work, but the Committee think that this duty should be that of the First Resident Surgeon, and that he should be a permanent official. Present incumbents should not be disturbed, but the Committee think that on their obtaining preferment, the rule suggested should be adopted.

"The *Native Assistant Surgeons* who are teachers in the Sealdah Hospital exercise the privilege of practice. As the questions of medical education at the Campbell Medical School and of the rules under which Assistant Surgeons are now admitted into the service have still to be considered by the Committee, they refrain at present from making any recommendations as to these officers.

"XX.—That *no medical officer* of any grade whatever should be (under pain of dismissal from Government service) allowed to have an *interest in any dispensary or druggists' shop*."

These paragraphs contain the definite orders of Government. We find that (1) certain I. M. S. men are permitted private practice under the distinct proviso that it does not interfere with their public duties. (2) That the resident medical, surgical and obstetric appointments of the Medical College and Presidency General Hospitals should be held by *junior men for two years only*. (3) That the professorships of Physiology and Pathology should be *independent appointments*. (4) That the Resident Surgeons of the Presidency General Hospital are prohibited private practice. (5) That Government medical officers are *"prohibited from having any interest in a dispensary."* This prohibition naturally includes *"a private hospital."*

Now let us see how far these rules are adhered to, either in spirit or intention, or literally.

(1) *I. M. S. men are allowed private practice, "provided it does not interfere with their public duties."* In an article on "CONSULTANTS IN INDIA" in the *Record* of the 17th October 1900, we had the following remarks:—

"Taking Calcutta as an example, we find the "consulting" I.M.S. surgeons, physicians, gynaecologists, ophthalmologists, etc., doing the very mixed work of general practitioners. They are at the beck and call of every

family they have contracted to attend yearly for a stipulated fee, day or night. Of course, as old and experienced civil surgeons they are good "all-round" practitioners, and remarkably well fitted for such work. But as "specialists" and "consultants," they must and ought to assume their legitimate role as such, and eschew work which does not come within the domain of their "speciality." When one comes to consider the arduous and onerous duties of a physician or surgeon to a large public hospital, his labours as a clinical teacher of a large class of students, his liability to be called upon to attend any serious case in his hospital, and his moral as well as his legal obligation to be accessible for such important and urgent official duty, it becomes transparently clear that such a man should, in simple and honest regard for his official duties, for which he receives a fairly handsome State salary, be within call for such work. *To indulge in general and family practice renders honest execution of public duty of the kind here indicated either absolutely impossible, or at least a very precarious possibility.* But this fact in itself gives prominence to a clear and emphatic duty on the part of I.M.S. practitioners. They should, without any administrative pressure, which must come sooner or later, relinquish all yearly contracts as family doctors, and all general casual out-door practice."

The Director-General of the Indian Medical Service may close his eyes to the patent facts revealed in this quotation, but it is a universally felt grievance that I.M.S. men attached to the Medical College Hospital do not perform their "public duties" fully and satisfactorily, and that "private practice" does, very materially and seriously, hinder and "interfere with" the honest performance of their "public duties." A strong man and an honest man at the head of the I.M.S. would put a stop to "private practice" by I.M.S. men at once, in the interests of the public, and allow these G. Pa. or so-called consultants, nothing but consultative practice. No reform in this direction can take place, however, till the I. M. S. is presided over by an impartial and level-headed officer. A flippant courtier will simply wink at failings and wrong-doing, for fear of estranging the good-will of the men in his own Service.

(2 and 3.) *The resident appointments at the Medical College Hospital should not be linked to professorships.*—It is astounding how the orders of Government with regard to these posts have been disregarded. As things have been going on for some time, we find the Professorship of Physiology linked to the resident surgeoncy, and the Professorship of Pathology linked to the resident physicianship, and that both the men occupying these resident posts are not junior men, for one is a senior Major and the other a senior Captain of the I. M. S. No two other members of the I. M. S. could be better fitted for these professorships but, according to the orders of Government, they should not be held by resident officers, for the simple reason that the work of a professor in either of these allied sciences in Medicine, demands the *whole time* of its incumbent. The "wisdom of Government" has enunciated this principle, and it is sound and just, not only for this reason, but also for the reason that the patients in the hospital must

suffer in 'view of such burdens being thrust upon resident officers. We find also a *senior* I.M.S. Captain as the obstetric resident. Then again the rule of only *two years' incumbency* is not followed in the General Hospital also. It is clear that the object of Government is to give as many junior I. M. S. men as possible an opportunity for special training, by making these posts tenable only for two years. It is unjust, therefore, to allow matters to go on as they are at present. Will not Colonel HENDLEY, the Inspector-General of Civil Hospitals in Bengal, who is regarded as "a strong man," do his duty in this matter?

(4 and 5.) *Further prohibitions as to private practice and as to interest in private concerns.*—In this connection we find that the Resident Surgeons of the Presidency General Hospital are as strictly prohibited from private practice as are the residents of the Medical College Hospital, and we ask if it is not true that this rule is regarded in the breach rather than in the observance. We have no desire to specify instances, but since rules were made to be obeyed, and it is thought that their proper observance is for the public good, we venture to drop this hint *pro bono publico*. So likewise in the matter of I.M.S. men "linking themselves" by unwritten contracts, not actually with "private dispensaries," but with such a commercial institution as a "private hospital" with South African proclivities. Surely this is a breach of "service decorum," if it is not a barefaced, though cunningly devised, method of violating the spirit, as well as the letter, of Government orders, which are fringed with the ominous penalty "under pain of dismissal from Government Service." We venture to suggest that if two of the I.M.S. "professors" of the Medical College would spend as much of their time with the public patients under their care in the public hospitals as they do with patients in the "private hospital" referred to, there would be less ground for general complaint that their public duties are being interfered with and neglected.

DIAGNOSIS AND SURGICAL TREATMENT OF TROPICAL LIVER ABSCESS.

In the Section of Tropical Diseases at the last annual meeting of the British Medical Association, Mr. W. JOHNSON SMITH, F.R.C.S., Surgeon, Seamen's Hospital Society, spoke on the Diagnosis and Surgical Treatment of Tropical Liver Abscess. We cull the essentials of his observations. After indicating the marked improvement during the last quarter of a century in the operative treatment and diagnosis of certain morbid conditions of the liver, resulting necessarily in an improvement in their prognosis, the speaker, on the basis of statistics quoted, said that he believed there was no necessity at the present day to anticipate any serious questioning of the absolute necessity of bringing under surgical notice any case of supposed tropical or amœbic abscess of the liver. The spontaneous cure of such a condition, even though the collection was a small one, was very problematical, and though, perhaps, for the subject of such disease, spontaneous rupture through the lung might be the happiest

event, it could not be overlooked that, while waiting for such not improbable result, the abscess might extend in a much less favourable direction. The need for surgical aid in cases of supposed abscess of the liver was urgent, not only for strictly therapeutical purposes, but also in a large proportion of cases 'for the sake of obtaining a certain and precise diagnosis. Except in those cases—a small minority—in which the abscess formed a well-marked tumour in the right hypochondrium, the determination of hepatic suppuration and the localisation of the disease, and also of the existence of one or a plurality of collections, was almost always attended with difficulty and uncertainty. This uncertainty was mainly due to two causes: (1) Most of the symptoms given in text-books were met with in other morbid conditions of the liver; and (2) they were often associated with, and masked by, those of dysentery and malaria. The temperature, shoulder tip pain, rigidity of the rectos, localised tenderness, chemical examination of the urine, were each and all unreliable symptoms. The recent employment of skiagraphy as an aid in diagnosis did not afford much help, for, besides requiring the aid of an expert, it could not do more under the most favourable conditions than assist the not very difficult diagnosis between pleural effusion and an enlarged liver. The strictly clinical signs of liver abscess as given in text-books varied considerably in diagnostic importance. In his own experience, the speaker had relied on the following: Residence in a hot country (the key-note): history of dysentery or chronic diarrhoea: tenderness over the liver, most marked at one spot: shoulder tip pain: gastric irritation: emaciation with sallowiness: depression: irregular temperature, with tendency to the remittent type: characteristic position, the patient lying on his back with the chest raised and the lower limbs slightly flexed. If in addition the patient presented in the right hypochondrium a fluctuating swelling over the most prominent part of which the skin was oedematous and congested, nothing could be more simple; but, unfortunately, such cases were in a minority. The most difficult of all were the very rare instances in which a small, single abscess is situated in the left lobe of the liver. The most reliable aids to diagnosis, however, were exploratory puncture and exploratory laparotomy—the former for preference—for, though the latter, if performed with proper precautions and care, was a safe operation, the former was much less alarming and troublesome. It was doubtful also whether laparotomy could, in the majority of cases, afford more help than simple puncture, and in the subsequent plan of treatment it would be found necessary to attack the seat of the disease by the same methods and the same direction as when the presence of pus had been revealed by a simple puncture. Moreover—and this was a strong, though perhaps a sentimental, objection to laparotomy as an exploratory measure—there was the probability that the exposed and handled liver might be found to be quite healthy. It would of course be difficult without laparotomy to find out a small abscess in the left lobe, but such a condition occurred only once in fifty cases. In case of failure with exploratory puncture, should high fever, sweating and exhaustion still persist, after an interval of a few days it should be again tried, and, if still a failure,

esort be had to exploratory laparotomy. If, as is usual, the characteristic fluid of a liver abscess be drawn up into the syringe and the patient is anaesthetised, it was advisable to complete the operative treatment at the same sitting, and to substitute the scalpel for any variety of puncturing apparatus, and to have recourse, according to the situation of the cavity, either to thoracotomy or some form of abdominal section. Thoracotomy almost always implied a transpleural incision, which, notwithstanding its unsatisfactory nature and the increased risk of infection by opening up two large serous cavities and the possibility of collapse of the lung, had, in suitable and favorable cases, on the whole, been a satisfactory operation—perhaps more satisfactory than any other operation for liver abscess. The surgeon's chief care was to guard against the risk of subsequent infection of pleura and peritoneum. The speaker thought it would be well to apply in all cases tests for both general and local leucocytosis. Should the fluid at the exploratory puncture exhibit leucocytosis, an effort should be made to shut off both the right pleural and the abdominal cavities before the cavity in the liver was opened and emptied. The best plan was perhaps VOLKMANN's method of plugging the open wounds in the chest wall and diaphragm with sterilised or antiseptic gauze, and postponing, for two or three days—if such delay were free from risk—the final stage of the operation. Operative treatment of liver abscess revealed by puncture of the anterior wall of the abdomen consisted in an abdominal section to a limited extent. In consequence of the invariable presence of adhesions in such cases, the knife could often be directly passed into the abscess without any exposure of the peritoneal cavity. The only cases in which the speaker would refrain from operating, excluding those in which the patient was much exhausted and almost moribund, would be cases in which there were clear indications of a spontaneous rupture of the abscess into the right lung.

Etiology of Gall-Stones.

F. C. SHATTUCK (*Philadelphia Medical Journal*) enumerates the well-known causes of biliary calculi as: (1) Cholesterolin, bilirubin calcium precipitated by changed reaction, bacteria of various types, foreign bodies. FARRICHS and NAUNYN give stasis, catarrh and changed reaction as the three chief causes. (2) Age, very uncommon in childhood, rare under thirty, somewhat common between thirty and sixty, very usual after sixty years. (3) Females suffer from them in the ratio of four to two. (4) Anything predisposing to stasis; here are felt the influence of age with its less active or slightly pathological metabolism, of sex with the sedentary life of woman, of enforced quiet in heart disease, of confinement among the insane, of altered anatomical relations in floating kidney, gastroptosis, pregnancy and lactation. (5) Bacteria are very important. Modern methods show: (a) Sterile foreign bodies do not cause gall-stones, though a sterile gall-stone may be penetrated at least by the colon bacillus; (b) the contents of the hepatic and cystic ducts are usually sterile; (c) those of the common duct are usually infectious directly from the duodenum; (d) gall-stones have been experimentally produced; failures have followed the use of virulent cultures, while attenuated cultures with or without foreign bodies have succeeded; (e) bacteria are found in a very considerable number of gall-stones; (f) the clumping peculiarity of the typhoid bacillus seems to be a very active factor and has succeeded experimentally; (g) the bacillus coli communis and bacillus typhosus are the most potent generators of biliary calculi.

COMMENTS AND NEWS.

THE DOCTOR IN THE WAR.

IT matters not how, and it differs not when,
Or whither the story first came,
'Twas told in a letter—that's all that I ken,
I can't even give you the name.

"The night it was sultry and sweltering hot,
And crowded together we lay.
'Hospital,' call it? I tell you 'tis rot,
The papers can say what they may.
Tents that were struck by some yeomanry men,
Canvas that soon was soaked through,
A blanket apiece—I tell you, Boy Ben,
The veldt aint no pillow to woo!
Them orderlies, rough, and devilish raw,
When Mausers are lodged in your bones,
They're well meaning lads, but I'm hanged if I saw
Chaps ever so callous to groans!
reckon, my lad, that you don't know the worth
A woman's soft tenderness means,
When writhing in pain on bare Mother Earth,
'Taint a matter, I tell you, of dreams!
'Sister,' we called her—my God, what a face,
'Twas made for an angel above;
Each man, as she moved in that death-stricken place,
Thought of Christ, and of mercy, and love.
While raising some poor lad with tenderest care
To moisten lips parched with the thirst,
Her gentle 'Poor boy—may God help you bear!'
Just made our hearts ready to burst.

The doctor—Great Scott! what a fiend for work,
In the rear, or out under fire!
Should any bloke hint that his duty he'd shirk,
Just tell him from me he's a liar!
The puzzle of all was his devilish luck—
Cool as you please under fire,
Always in danger, yet never being struck.
Head or hand never seeming to tire.
That sultry night as he passed through the tent,
Full of wounded stretched out on the veldt,
He paused and he stooped by each bed as he went,
With a look that just made itself felt.
A gunner who lay on the opposite side
That day had been shot through the chest;
'Poor beggar,' he muttered, 'he's had his last ride,
Save the one to his long home and rest.'
How well I remember the look that he gave
That youngster a lying aside me!
I knew by his glance he was booked for the grave,
And his dreaming of home not to be.
By some he would kneel and ask how they felt,
Or see that a bandage was right,
Give them some stuff that he took from his belt,
And wish them good luck for the night.
Ah! Ben, of what's 'forrard' how little we know,
Or when our last message we'll send.
But if not 'on duty,' we're kept here below,
Be certain 'taint here it will end.
Next day we had news of a yeomanry mess,
While scouting a neighbouring hill;
They went out some twenty—they came back twelve less,
Some wounded were lying about still.

The doctor went off with his stretchers and men,
To get the poor injured chaps in,
(My pen just refuses to write it you, Ben.)
But he was the first they brought in!
No searching for bullets—for shot through the heart,
The doctor had passed to his rest,
Right bravely and nobly he'd acted his part—
'Taint meant we should know what is best.
"Rest" did I say, Ben? I'm blowed if I know
How ever our doctor could rest!
If now he is reaping what here he did sow,
Then the doctor, he's reaping his best!

But now it is time that I finished my tale—
The doctor just lost me my track;
There's but a short spell for the Kimberley mail,
And so to that night I'll hark back,
Not long had the doctor gone out of our sight,
In vain I had tried for a sleep,
The candles that lighted the tent for the night
Began in their sockets to weep—
When sounds of sweet music stole into my ear,
And startled me there as I lay.
The low tenor notes of the lad that lay near,
Broke in on the dawn of the day.
I listened in wonder, my heart it beat quick,
As I heard the sweet musical tones
Rising so soft midst the dying and the sick
And mingling along with their moans—
Of "England" and "Home" and of "Beauty" he sang,
That his "duty" that day he had done.
No wounded one there gave a thought to his pang,
For of thoughts, save of home, he had none.
While slowly the sounds died away on the air,
And nought but men's breathing was heard,
A candle flared out, and revealed to us there
The smile that the sleeper's face stirred,
And then came a pause while I waited to hear
What else the boy dreamer might sing,
And visions of loved ones to eyes drew a tear,
Only thoughts of those dear ones could bring.
My God, how my heart seemed to rise in my throat,
As again the sweet music awoke,
And sadly the notes through the air seemed to float,
In the strains that the soldier well knows.
For now 'tis of "Home, sweet home" that he sings,
And the bars of "where'er we may roam"
Seemed to grip and to clutch at my heart's very strings,
As he murmured, "there's no place like home!"
And now came a hush that was like unto death
'As the Sister came into the tent;
She heard but his rapid and fast failing breath
As over the singer she leant.
A gleam of soft light from the fast rising sun
Passed straight through a small canvas rent,
And lit up the face of the death-stricken one
As his last loving message he sent.
She knelt down beside him to catch his faint words,
And slipped her cool hand into his.
"Tell mother—my last thought—stay—hark to the birds!
Are they singing?—Be sure and tell Liz!
The Bible she marked—and the locket of hair—
Bob my revolver.....now sing me the hymn—
'Lead, kindly light'.....choir—she's sure to be there—
Mother—old father—God! all seems to swim!"

Then fainter he whispered, "Bend down very near—
Write to Liz—I died loving her best;
To Bob—say to him I sold life—very dear—
For England".....He'd gone to his rest!

—H. MACNAUGHTON-JONES.

SOME SUGGESTIONS FOR THE IMPROVEMENT OF SANITARY AND MEDICAL PRACTICE IN THE TROPICS.

DR. RONALD ROSS, D. P. H., M. B. C. S., of the Section of Tropical Diseases at the annual meeting of the British Medical Association for 1900, suggested some noteworthy improvements in medical organization in the tropics. We take the essentials of the paper from a report in the *British Medical Journal*.

1. *Instruction in Animal Parasitology.*—Few medical men had made a particular study of the organisms of the principal tropical diseases, such as malarial fever, dysentery, ankylostomiasis, elephantiasis, endemic hæmaturia, and a knowledge of comparative parasitology was still more rare. The only remedy for this was a greater attention to animal parasites in the ordinary pathological curriculum.

2. *Instruction in Tropical Medicine.*—This was essential not only in the case of those who had joined the medical services, but with all practitioners, for hundreds were called to serve as ship doctors or as private practitioners in the tropics, or suddenly enlisted in wars, such as in South Africa.

3. *Special Questions in Examinations.*—Every examination paper on pathology and medicine should contain at least one question on animal parasitology and one in tropical medicine.

4. *Literature.*—There was a crying necessity for greater facilities in the way of small up-to-date libraries in all the leading towns in the tropics, especially in connection with the principal Government hospitals. It was impossible to understand why such a want had not been attended to long ago. It would perhaps be possible to arrange, through the library of the British Medical Association, an agency for the supply of monographs to the tropics, either by loan or sale.

5. *Microscopes.*—Antitoxins, antivenene and apparatus for bacteriological diagnosis should exist in the principal towns.

6. *Medical Regulations.*—These should be compiled and issued with the greatest care: they were in a bad way now in the tropics.

7. *Municipal Sanitary Regulations.*—The same could be said of these. It seemed that these regulations should be in the charge of a skilled central authority.

8. *Organization of Research.*—This could be done in three ways: (a) By the foundation of research laboratories—a method too costly and not likely to give the best results for the least money. (b) By the appointment of specialists to prosecute certain definite lines of investigation—a better method, but also somewhat costly and often likely to fail on account of the difficulty of selecting the suitable man. (c) By the encouragement of private research by large pecuniary rewards. This was the best method. It was impossible for men who had to live by their profession to undertake such duties. The occasional donation of a prize of some thousands of pounds for really notable investigations was probably the most efficient, though not the only, way to secure rapid scientific advance in the profession.

9. *A Central Scientific Authority.*—There had long been felt a need of some such institution to encourage and support medical scientific research in the tropics and to insist on those reforms in medical and sanitary practice which the progress of science continually demanded. "Perhaps there was already the necessary organization. The Royal College of Physicians and the Royal Society were already stirring in the matter of tropical medical science, and these and other societies would, it was hoped, soon "force the running still more."

BOGUS AMERICAN DIPLOMAS.

THE *Hindu Patriot* says :—RAI SARADA KANTO LAHIRI, M.D., who is alleged to have been one of the party concerned with Dr. J. ARMSTRONG, of Chicago, for selling bogus diplomas in India, has recently published a declaration to the effect that he is quite ignorant of the charges against him, that he is not a holder of bogus diploma of M. D., that he does not want to defraud the people of India by selling them things worthless and fraudulent at the same time. He declares to have obtained the degree of *Doctor of Medicine* from the International University of Chicago, chartered by the State of Illinois, according to the laws of Illinois, after having passed duly the examination held for the degree and securing seventy-five per cent. of marks on the whole. He further declares to have been decorated with the degree from the halls of the University before a Council convened, and so it would be evident that he has not purchased it, but rather he has earned the fruits of his own labour—has secured the degree with all the rights and privileges pertaining to it everywhere, after adducing sufficient proofs of his wide knowledge and ability in the science and practice of medicine. By virtue of the International law he claims to be recognised here as he has been recognised in the State of Illinois, which granted charters to the University under whose bye laws again he has been graduated as an M. D. He has attached with the declaration printed copies of the diploma of M. D., the question papers, the certificate of the President of the University attested by the Secretary, and a few other letters in order to clear away the suspicion from the minds of the public that he is a holder of bogus diplomas, and to make them believe that he possesses the genuine degree of the International University of Chicago, incorporated under the State Laws of Illinois. In reply to the charge that though the International University of Chicago is a chartered one, still its President is a fraud, and he may have been cheated by him, he says that if Dr. ARMSTRONG be really a fraud and has really deceived him, it is not his fault, but of Dr. ARMSTRONG and that of the State which has granted charters to such a base, dishonest person as he may be; for he has received the degree from a chartered University of the State of Illinois, and not from Dr. ARMSTRONG and his associates. He is not in any way connected with the fraudulent traffic of the purchase and sale of bogus diplomas, either in this country or anywhere else. He did not know the President nor any of the office-bearers of the University at the time when he applied to the office of the University for being examined, in order to be able to get the degree and "ent graduate fees." He has petitioned His Excellency the Viceroy as well as the Secretary of State for India, Secretary of State for Foreign Affairs, and the Consul-General of the Republic of the United States of America, to consider his case, and to take such necessary action as may restore his professional reputation, and thereby secure the means of subsistence to him and of his family.

ABOLITION OF THE USELESS CORONER'S OFFICE.

THE *Journal of the American Medical Association* says :—The recent carelessness of coroner's officials in Chicago, in a widely exploited case of fraud against insurance companies, has directed attention again to this "relic of barbarism"—the coroner's office. It is being urged strongly that the office be abolished and the work the coroner now pretends to do turned over to the police and the health department. There is no question as to the antiquated and unsatisfactory nature of the inquiries carried on by the coroner's office. The jury system is abused and prostituted, and the entire affairs of the office, both medical and administrative, are handed over completely into the hands of politicians without a trace of training or expertness in medico-legal matters. It is no wonder that justice miscarries under these circumstances, that people have no confidence in the coroner's verdicts, and that stories are afloat of extortion carried on across the bodies of the dead. But the coroner is an elective officer, whose election and whose duties in general are prescribed by State law. On paper his powers are as autocratic as can be conceived. The words of the statute give him power to step in wherever he has reason to believe or suspect that a body lies dead from unnatural or unknown causes. To change the present law so as to provide for a modern, a more intelligent and a more economic method of inquiry into the nature of the causes of death under these circumstances, would require legislative action and submittal of the proposed change to the people at large—a cumbersome and difficult procedure, sure to be met by obstacles of diverse nature. The abuses and shortcomings of the present system are especially felt in the large cities. In the country, where most individuals die peacefully and naturally, the people are not discontented with the coroner, and they have no occasion to make close acquaintance with the workings of his office. In a large city like Chicago, however, the present coroner's system has outlived its usefulness long ago. Inasmuch as the essential part of the coroner's work is of a medical nature, namely, the determination of the cause of death in a variety of cases, it follows that physicians are interested, especially in the proper administration of this duty. The medical profession must take an active and leading part in the attempt at securing improvement in the present methods, which are inadequate. Local and State societies should bring up matters of this sort for study and discussion, in order that the most serviceable plan may be evolved. This phase of medico-civic affairs certainly merits careful investigation.

THE USE OF OPIUM, GANJA, AND INTOXICATING DRINKS.

DRUNKENNESS has always prevailed in India among certain classes; but, as a nation, the people have been temperate for many centuries.

It is deeply to be regretted that, of late years, drinking habits have been acquired by some educated Hindus, whose forefathers never touched intoxicating liquors. This is largely attributable to European example.

When English began to be studied in India, some young men thought that they must imitate English habits as well as learn the language. Among other things, it was considered a mark of manliness and a proof of advance in civilization to use intoxicating drinks; and a liquor generally selected was brandy, the strongest spirit. The effects have been most disastrous. As the *Hindu Patriot* says :—"Wealth, rank, honour and character, health and talents, have all perished in the blighting presence of this huge monster."

The Government revenue from spirits, toddy, opium, bhang, etc., is about 5½ crores a year, probably representing an expenditure of double that amount including the gains of the vendors. All this might be saved and turned to useful account.

Happily there is strong movement in England in favour of temperance reform. Numerous societies have been established, the members of which pledge themselves not to use intoxicating liquors. Associations of this kind for the young are called "Bands of Hope." In the United Kingdom they now number upwards of two millions of members.

Indians are earnestly advised to adhere to the temperate habits of their forefathers. The Greeks had a saying, "Water is best." They should also try to induce others to follow their example. Temperance reform should be promoted in India as well as in England. Mr. W. S. CAINE, a zealous friend of the cause, has visited this country more than once on its behalf, and a number of societies have been formed which should be heartily supported. Municipal Commissioners and others should seek to reduce, as far as possible, the number of arrack and opium shops.

ECONOMIC PRODUCTS.

We quote from the *Chemist and Druggist* :—The Government of India has recently established an Economic and Art Department to be located at the Museum of India, Calcutta. Dr. GEORGE WATT, O.I.E., F.L.S., is in charge, and Mr. DAVID HOOPER, F.I.C., F.L.S., has been appointed Curator. Dr. WATT's work during many years in the development of the economic resources of India, of which his "Dictionary of Economic Products of India" was an outcome, is a guarantee that results of value in materia medica and in more extensive departments of commerce may be looked for. Mr. HOOPER is well known as the author of many valuable researches in the same field, and as part author of *Pharmacographia Indica*. Some indication of the methods in which the specimens are made to speak for themselves in the re-arrangement of the museums is gleaned from a report which Dr. WATT has presented to the Government on the Economic Section, in the course of which he mentions that a correspondence was instituted by the Imperial Institute at the request of Messrs. ROWNTREE & Co. into the subject of edible gums, and a very fine set of commercial samples of the chief gums of this class has been brought to the museum from Burma, Bombay, North-Western Provinces and Oudh, the Punjab, and the Central Provinces. The gums collected were as follow :—*Acacia arabica*, *A. Catechu*, *A. Jacquemontii*, *A. modesta*, *Anogeissus latifolia*, *Cochlospermum Gossypium*, *Mangifera indica*, and *Moringa pterygosperma*. Speaking of kino, he says :—"Over the specimens of kino a stem of *Pterocarpus Marsupium* has similarly been fixed, showing the excoarited bark (something like the appearance of a fish-bone) with the receiving apparatus into which the fluid is collected in Malabar."

COMPOSITION OF INDIAN COWS' AND BUFFALOES' MILK.

We quote from the *Indian Daily News* :—Dr. WALTER LEATHER, Assistant Agricultural Chemist to the Government of India, furnishes some useful information in a recent number of the Agricultural Ledger, upon the subject of the composition of Indian cows' and buffaloes' milk. The composition of cows' milk has been found in England to be very regular for different breeds, and to possess a relationship between the several component parts for all the breeds. It is of importance, so Dr. LEATHER thinks, to know whether these relationships hold good for Indian breeds of cows, and

to what extent they vary in the case of the buffalo. The analyses published by the Madras Board of Revenue are only two in number, and are therefore quite insufficient for the purpose in any case. In addition, however, they show the proportions of proteids and lactose to be altogether different from anything met with in the case of English cows' milk. Dr. LEATHER finds that the milk of the Indian cow contains a high proportion of butter-fat, varying from 4 up to 6 per cent. Buffaloes' milk contains usually much more, varying from 5 or 6 per cent. up to as much as 10 per cent ; that the percentage of proteids (albumen and casein) usually varies in cows' milk from 8.1 up to 3.5 ; in buffaloes' milk from 3.5 up to 4.3—such proportions as 5.0 and 5.2 per cent. of proteid, as stated in the Madras publication referred to, are never found—and that the percentage of milk sugar (lactose) in the cows' milk varies from 4.4 to 5.0, and in buffaloes' milk it is present in about the same proportion. It is never so low as is stated in the Madras publication. The percentage of mineral matter in cows' and buffaloes' milk varies from about 7 to 8, as it does in English cows' milk.

DEBT, THE NORMAL CONDITION OF INDIA.

ABOUT 80 years ago, CAREY, the veteran pioneer missionary of India, wrote :—

"There may exist circumstances in the habits of a people sufficiently powerful to defeat the most benevolent views of its rulers, and to entail misery where there is every preparation for the enjoyment of happiness.

"Among the numerous causes which contribute to exclude happiness from the people of India is the universal tendency to borrow which pervades the country. This disposition to borrow is not confined to one province, to one town, or to one class of individuals. It pervades the whole country with all the inveteracy of a second nature. The country is separated into two classes—the borrower and the usurer.

"An independent husbandman, free from debt, and looking forward with delight to the whole of his little crop as his own, is almost a phenomenon in the country. Most of them, through the wretched system which now prevails among them, are in debt perhaps for the seed they sow, are supplied with food by their creditors during all the labours of the field, and look forward to the end of the harvest for the payment of a debt, to which at least forty per cent. is added, and which, through the way in which it is exacted, is often increased to fifty per cent."

REAL CAUSE OF FAMINE AND POVERTY IN INDIA.

"THE regular drainage of wealth out of India has been variously estimated at from 30 to 70 million pounds sterling a year. Sir CHARLES DILKE said : 'Our kingdom and people together draw from India some sixty or seventy millions sterling a year in direct income.' Madame JULIETTE ADAM writes : 'In 27 years India has been drained to the extent of 500 millions. We will be considerably within the mark if we reckon it at the rate of 50 millions a year.' Now, India has been drained to this extent for the last hundred years, and the process is going on with increased volume every year. What wonder then if India is pauperised to-day ? Lord CURZON calculated last year that the failure of the monsoon throughout India, with the exception of our two provinces, caused a terrible loss to the country. That was a great calamity indeed ; it represented the loss of the earnings of the majority of the Indian population. But according to the calculation of Lord CURZON himself, it was only about 25 millions. Compare with this exceptional and abnormal item the regular annual drainage of fifty millions, and will anyone still wonder at the cause of the famine ? As we have said the world over, whether in the past or the present, there is not a parallel to it."

SUBARACHNOID INJECTIONS OF COCAIN AS A SUBSTITUTE FOR GENERAL ANÆSTHESIA.

PROFESSOR A. M. PHELPS, M.D., A.M., of New York, says:—Every surgeon has patients upon whom he has operated under local cocaine anæsthesia administered hypodermically, and he knows that there is an idiosyncrasy in some of those patients against cocaine, and if profound anæsthesia was produced by the injection of a dose of cocaine to one individual, which would be a small dose in another individual, death would certainly be the result in certain cases if a full dose were given.

Then, in conclusion, let us hasten slowly. Let these experiments be done by men of mature judgment, of long experience, of clear heads. And so long as the profession has an anæsthetic in ether that has so low a rate of mortality, or in nitrous-oxid gas in which the mortality is almost nothing, they will be loath to substitute for it a method of anæsthesia which must necessarily have a great mortality.

I was fortunate enough to listen to the discussions upon this subject while in Paris last summer, and I must say that I was very favorably impressed with what I saw until I learned that two deaths had already occurred there during the summer from this method of administration of cocaine. And now that we are occasionally hearing the mutterings of dissent in the profession on this side of the water, and hearing of a death or extremely alarming symptoms, let the profession take warning.

ASSISTANT SURGEONS OF THE STRAITS SETTLEMENTS MEDICAL SERVICE.

It is very agreeable news to learn that that hard-worked and deserving band of medical men who form the backbone of the Straits Settlements Medical Service, and who hitherto have been styled "Apothecaries," are now to be designated Assistant Surgeons. They are all men who hold the diploma of the local Medical Colleges, chiefly of Madras, and they are therefore well rid of a designation that was a misnomer in every sense of the term. They owe their success in this matter to the newly appointed Principal Medical Officer of the Straits Settlements Medical Service—**Dr. T. S. KERR**—an officer who has already done 17 years of excellent and approved service in the Straits Settlements, during the whole period of which he has evinced the kindest interest in the junior members of his service. We congratulate our brethren of the Straits on their well-merited change of designation.

THE GREATEST MEDICAL NEED REQUIRING LEGISLATION.

The Canadian Practitioner, writing about the use of proprietary medicines by the public, says:—Here then is a crying evil. What is the remedy? One would be to prohibit the sale and advertising of proprietary medicines, but especially if they contain any of the drugs in the poison or noxious list. It may be some time before our legislators can be educated up to this standard. There then remains a partial remedy that should at once be put in force. The exact composition of every proprietary medicine should be printed in plain language on the wrappers. In this way the people could see for themselves that some greatly vaunted medicine was only ditch water. Further, these nostrums could be ordered off the market if they contained noxious or poisonous drugs.

SHORT ITEMS AND PERSONALITIES.

At a meeting of the Senate of the Bombay University, to be held in the Sir Cowasji Jehangir Hall of the University on Tuesday, the 29th instant, consideration will be given to an offer of Rs. 6,000, in three and a half per cent. Government paper, from Mrs. Byramjee Nusservanjee Koyajee, for the foundation of a scholarship and a silver medal in the name of her husband, the late Surgeon-Captain Byramjee Nusservanjee Koyajee, of Her Majesty's Indian Medical Service, to be awarded annually to the Parsee candidate who passes the matriculation examination with the highest number of marks in elementary science.

Dr. Turner, the newly-appointed Health Officer for Bombay, leaves England in the *India* on the 30th instant, and will enter upon his duties in the middle of February. **Mr. W. Maughan**, Associate Member of the Institute of Civil Engineers, who has recently been appointed Deputy Executive Engineer for Drainage, Ordinary Branch, Bombay, will arrive at the end of the month. **Mr. Maughan**, who was selected from about sixty applicants, has been for eight years in the office of **Mr. Santo Crimp**, and has been engaged on **Mr. Crimp's** latest drainage schemes as Resident Engineer.

We all know the story of the grocer who sold "new-laid eggs," "fresh eggs," "cooking eggs," and "eggs," and that of the dairyman who was prepared to supply either "pure milk" or "milk guaranteed pure," according to price. But, if we may believe a Belgian paper, there is a dairy in the outskirts of Brussels which exhibits the following price list:—"Ordinary milk, 40 centimes the litre; milk drawn from the cow in the presence of the customer, 75 centimes; drawn by the customer himself, one franc."

Dr. H. Beale Collins, the Medical Officer at Kingston-on-Thames, suggests in the *Municipal Journal* that there should be a city for consumptives only. It would be a rural city, governed by carefully prepared rules and bye-laws. The most important point would be the laying out of the site in straight, broad streets, running at right angles to each other, so as to allow free currents of air through the city. The inhabitants would spend their lives in the open air.

A gentleman who applied for the position of resident house surgeon to Cardiff Infirmary having been rejected by the Medical Board on the ground that he was too highly qualified, the ruling has been overturned by the executive committee, and the honorary medical staff are considering whether to resign in a body.

Massage as a separate and independent study is the latest novelty at the Berlin University. Two courses of massage—one of six months' duration for students and one of one month for doctors—will be held under Professor Zibudowski's direction at the new University institute for massage and Swedish gymnastics.

Several cases of rabies have occurred lately among dogs in Madras, many animals being destroyed in the S. P. C. A. Infirmary. One, being treated by the owner for distemper, bit two children and was brought to the infirmary. Under treatment it showed symptoms of madness in a few hours. The children were sent to Kasauli.

Calcutta has had some novel amusement in a walking match between the Health Officer and a pony. Anybody who has walked a few times alongside of a stud knows that there is as much credit to a pony in losing a walking match to a man, as there is to a school-boy in being an "Entrance fail."

Major Wyville Thomson, of the Indian Medical Service, who proceeded on active service to China, returned to Calcutta on Saturday. He has been ordered to rejoin his regiment, the 2nd Battalion of the 2nd Gurkhas, at Dehra Dun.

The equipment has now been completed of a plague hospital for Poona Cantonment at a cost for 150 beds of Rs. 19,778. Another thirty beds are to be added, should circumstances necessitate them, at a further outlay of Rs. 3,000.

There are several cases of enteric in Lahore, the latest sufferer being Dr. Ruther Williamson, an English medical missionary. This is unusual for Lahore, which, as a rule, is singularly free from enteric.

Major A. M. Davies, R. A. M. O., will continue in his present appointment of special Sanitary Officer with the Government of India until the end of the present cold weather.

A blizzard has taken place on the Continent and ten deaths from cold occurred in Paris yesterday.

WANTED—A THIRD GRADE HOSPITAL ASSISTANT to come to Burma on mutual transfer with the undersigned. Any one from Punjab or N.-W. P. will be accepted. For particulars, address :—

H. A.,
C/o Manager, "Indian Medical Record."

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE INDIAN MEDICAL RECORD will, upon publication, be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary, to elucidate the text, illustrations will be provided without cost to the authors. Address the Editor, JAMES R. WALLACE, M.D., F.R.C.S., 50, PARK STREET, CALCUTTA.

NOTICE.

All members of the Indian Medical Association are kindly requested to send their names in full with their present addresses, clearly written, to the Secretary.

Members who have paid their subscriptions and who have not received the membership certificates are kindly requested to notify the same to the Secretary.

Subscribers are requested to communicate any temporary change of address not to the Office of this Journal, but to the post-office through which they are accustomed to receive their Journals.

The Indian Medical Association fights the battles of the Medical Profession as a whole, and it takes up the cause of individual members as well. Join the Association and you will not be disappointed.

Medical Appointments, Transfers, Exchanges are easily and cheaply effected through our special short advertisement page. See terms and apply at once.

The *Indian Medical Record* offers the following prizes :—Rs. 10 to Rs. 16 for a good Original Article ; Rs. 5 to Rs. 10 for a good Clinical Report. Competitors must be subscribers to the *Record*.

Members of the Indian Medical Association will kindly note that while the entrance fee to the Association is fixed at Rs. 5, the annual subscription is reduced to Rs. 2.

Current Medical Literature.

MEDICINE.

Recurrent Insanity.

FROM a study of recurrent insanity, the following conclusions, among others, may be summarised :—

1. That recurrent cases form a large proportion of the curable cases admitted into asylums.
2. That in these cases hereditary predisposition to insanity is present in a greater number than in primary cases.
3. That alcoholic or other excess is a frequent factor in the causation of relapses.
4. That in cases in early life menstrual irregularities in the female and masturbation in the male are frequently present.
5. That the puerperal period and the periods of gestation and lactation account for a large proportion of female recurrent attacks.
6. That the climacteric period in both sexes is a potent predisposing or exciting cause.
7. That the majority of the attacks occur in middle life ; the first attack, however, is most frequent in the adolescent period, and is later in males than females.
8. That the prevailing forms of insanity are maniacal melancholic forms, being almost restricted to the middle period of life.
9. That the tendency is toward recovery, minor relapse being frequent before complete convalescence.
10. That the largest proportion of chronic cases is found in second attacks.
11. That in many of the cases a certain periodicity is established, the tendency, however, being toward chronic insanity.
12. That this class of patients furnishes many who are dangerous to themselves and others—a danger which is increased by the impulsive character of their acts and the frequent absence of marked premonitory symptoms before the onset of the attack.—HUGH KERR.—*Glasgow Med. Jour.*

Special Causes of Simple Fever in Children.

WORMS get more blame than they deserve for causing fevers and other disorders of childhood. In many cases the symptoms are due to other causes ; still worms are not a myth, and are sometimes the source of attacks of fever or other ailments. The worms most common in children are the round and pin worms. Their ova are taken into the body with the drinking-water, and from dirt swallowed by the child from the floor or ground containing some foul matter in which the ova are found. They may be taken in unclean milk, from particles of barnyard manure getting into it. Sterilising the milk, boiling the water, and seeing to it that the child has a clean place in which to play will prevent the disorder by keeping the worms from getting into the intestines. After they are once there, they must be gotten out by giving them something that will make them sick. The treatment for worms will be considered in another paper, so here I will simply add that the only sure symptoms

of worms is the finding of them in the stools, and that the secretions of a healthy digestive tract will usually destroy the ova of these troublesome parasites.

Local irritation is often a predisposing cause of simple fever. The excitement of the sexual organs arising from secret vice is sometimes the cause of fever in the young; eye-strain due to defective vision sometimes causes sickness at the stomach, vomiting, and fever whenever the child tries to study. This may often be remedied by properly adjusted glasses. In such cases a specialist ought to be consulted and the cause of the disturbance removed.

There are two diseases quite frequent in early childhood which often begin insidiously. These are tuberculosis and rheumatism. One of the first positive symptoms is the continuous moderate rise of temperature. It is not a simple, but a specific fever which marks the outset of these serious and often fatal disorders; but it is so often mistaken for such that it is well to mention it in this connection. The steady, daily continuance of temperature rise, with increase in the height of the fever, should lead a mother or nurse to suspect something more than a transient cause which can easily be removed, and should lead to consulting a physician. —*Good Health.*

Hæmorrhage from the Bowel.

THE passage of blood per rectum has been noticed as occurring in enteric fever, in ulcer of the stomach, and in dysentery; it may of course happen with any considerable breach of surface, but simple oozing without obvious rupture may also lead to considerable hæmorrhages. The way in which the blood is passed may give a clue as to the point whence it comes. In bleeding from gastric or duodenal ulcers the blood is considerably altered by the secretions, and forms a black, tarry, semi-liquid, or treacly mass (mælena); in hæmorrhages from typhoid ulcers the blood is equally unmixed with fæces, but brighter red and more fluid than in the former case, from the action of the alkaline contents; the blood in dysentery is in streaks or small clots, mixed up with mucous or pus or thin fecal matter, though from time to time small quantities of pure blood may be passed. Large quantities of blood may be lost from piles or from an ulcer of the rectum. Here the bleeding is generally caused by the act of defecation, the blood either streaking one side of the solid fecal mass or coming more or less pure in drops or streams after the motion is evacuated. In scorbutic, purpuric, and hæmorrhagic conditions (scurvy, purpura hæmorrhagica, acute yellow atrophy of the liver, malignant variola), blood comes from the rectum more or less mixed with fæces or pure, according to the part of the intestine yielding it or the freedom with which it escapes. —FREDERICK TAYLOR, M.D., F.R.C.P.—*New York Med. Rec.*

Hysteria in Childhood.

DR. HERMAN B. SHEFFIELD (*New York Medical Journal*) says the symptomatology of hysteria is characteristic for its changeability and multiplicity. In the United States it is observed, as a rule, in the following order of frequency: (a) Spasmodic affections (convulsions, spasm of the laryngeal muscles—croup—contractures, cataplexy); (b) sensory symptoms (painful sensations, anaesthesia, blindness, contracture of visual field, hemianopsia, deafness); (c) motor disturbances (paralysis of the extremities, paralysis of the laryngeal muscles—aphonia); (d) visceral and vasomotor disturbances (affections of the alimentary canal, dyspnoea, tachypnoea, hyperpyrexia).—*New York Med. Rec.*

SURGERY.

Fistula in Ano.

DR. COOKS (*Medical Monograph*) says:—

1. A careful physical examination of the lungs as well as of the entire rectum is to be made in every case.
2. Pulmonary tuberculosis is not necessarily a contraindication.
3. Do not stop until every sinus has been divided.
4. Remove all diseased tissue; large wounds are not to be feared.
5. Divide the sphincter but once, and then at a right angle.
6. Special attention is to be given to the mucous opening.
7. Invasion of the perineum is to be avoided, especially in females.
8. Systematic antisepsis is necessary.
9. Care and patience are required in the after-treatment.
10. In the after-treatment two warnings are to be heeded. Complaints of unusual pain, and increase in the discharge. Either of these may mean the formation of another abscess.
11. Hæmorrhage and incontinence are the chief dangers. Both are amenable to treatment and should not deter from operation.

Indications for the Mastoid Operations.

THE valuable paper read by BALLANCE on the conduct of the mastoid operation for the cure of chronic purulent otorrhoea before the Royal Medical Chirurgical Society has already been noticed in the *Medical Times* in the columns devoted to general surgery. The reading of this paper was followed by some remarks on the cases which require the operation, by Sir WILLIAM DALBY, who finally gave it as his opinion that the necessity for the radical operation would seem to exist in somewhat the following manner:

Firstly, undoubtedly in case where septicæmia has commenced.

Secondly, undoubtedly in cases where there is dead or carious bone in the tympanic cavity, accompanied by ominous symptoms often repeated.

Thirdly, wherever there is evidence of mastoid disease of long or short standing.

Fourthly, in a certain proportion of cases where there is evidence of dead or diseased bone, but a very doubtful history of ominous symptoms.

Fifthly, in a certain proportion of patients with intractable otorrhoea, in whom no bone disease can be detected, and in whom no history of ominous symptoms can be obtained.

DALBY'S concluding remarks are worthy of repetition. He spoke as follows:—"It will be seen, therefore, how very difficult it is to lay down definite rules as to local conditions only, which shall form a reliable guide in the selection of cases for operation;—how much allowance should be made for those surgeons who may be thought to operate without sufficient reason, as well as for those who have not seen sufficient reasons for so radical a treatment of what is apparently so common and not so serious a condition."

[The indications for opening the mastoid have received a very large amount of attention from many otologists. Sir WILLIAM DALBY'S words certainly give a fairly comprehensive review of the different conditions in suppurative middle-ear disease which should influence the surgeon in his

decision as to the advisability of an operation. We note, however, that Sir WILLIAM makes no allusion to the preliminary performance which occasionally in some cases averts the more serious procedure.]—*Medical Times and Hospital Gazette*.

Amputation of the Leg by Cocainizing the Spinal Cord.

WILLIAM E. LOWRE (*Cleveland Journal of Medicine*) reports the amputation of a leg without general anesthesia, but by cocainizing the spinal cord. The patient was a man, 64 years of age, and suffering from diabetic gangrene. With a long needle attached to an aspirating syringe, 2 drachms of a one-fifth of 1% solution of cocaine were injected into the spinal canal in the space between the last dorsal and first lumbar vertebra. In three minutes there was complete anesthesia of both feet and legs. The amputation was performed immediately and the patient felt no pain. In 20 minutes sensation was restored. At no time was motor power completely lost. There was no shock, as all afferent impulses were abolished. The pulse varied from 68 to 72 during the time of anesthesia. The patient suffered from headache and a tendency to fever and delirium the next day after the operation. After that the patient made an uninterrupted recovery.

Vasectomy for Enlarged Prostate.

REGINALD HARRISON, F.R.C.S., in the *Medical Fortnightly*, deduces the following conclusions: (1) That vasectomy has been shown to be specially effectual in the earlier stages of prostatic enlargement in effecting shrinkage of the gland and the restoration of the natural process of micturition. (2) That in cases in which there is evidence to show that the gland has in the course of degeneration assumed the form and structure of a fibrous growth the conditions are such, provided the symptoms of obstruction warrant the adoption of other measures than catheterism, as to render some form of prostatectomy preferable to either vasectomy or castration. (3) That when, as a consequence of sudden or protracted prostatic obstruction, secondary changes have taken place in the bladder itself, in the form of sacs, pouches, or trabeculation, the possibility of restoring its natural function by any means is extremely unlikely. Under such circumstances the induction of shrinkage of the enlarged gland will do good in affording a readier access for the catheter and in removing spasm, pain, or hæmorrhage connected with this or other similar process.

Prognosis of Dislocations at the Shoulder.

Do not be too quick to promise a perfect result after dislocation at the shoulder. The circumflex nerve passes closely around the surgical neck of the humerus, and often takes serious and lasting offence at the traumatism. Paralysis of the deltoid prevents abduction of the arm, permits gradual elongation of the capsular ligament, and recovery from it is usually slow and incomplete; hence the wisdom of a lagging prognosis.—WILLIAM V. MORGAN.

Wounds of Veins.

WOUNDS of veins are of importance both on account of the immediate and the remote effects they produce. The immediate troubles which have to be dealt with are: (a) dangerous hæmorrhage and (b) entry of air into the vein. The remote troubles are chiefly thrombosis, embolism, pyæmia and œdema of the part corresponding to the distribution of the vein. The immediate troubles are more common in connection with operation wounds, the remote troubles in accidental wounds.—OHENE AND BURGHARD.

OBSTETRICS AND GYNÆCOLOGY.

Remarkable Success in the Treatment of Eclampsia.

V. V. STROGANOFF says:—Out of ninety-two cases of eclampsia which he has had occasion to treat during the last three years, only five patients have died, and two of these were moribund when received. The third died from sepsis twenty-seven days after termination of the eclampsia, the fourth from pneumonia, and the fifth from atonic hæmorrhage four days after the eclampsia was over, the delivery being complicated in this case by a ventroflexion done four years previously. Seventy-nine out of the ninety-eight infants were saved. He considers eclampsia a self-limited infectious disease, the contagion air-borne, but so slightly virulent that no one except a woman in the puerperium is affected by it. His views have already been mentioned in the *Journal*, xxiv, pp. 735 and 1257. He treats it with a combination of morphin and chloral, the former for its influence on the sensory centres, and the latter to control the convulsions. By this means he arrests the attacks in twenty-four to forty-eight hours; the urine increases in quantity, and the secretion of mucous diminishes. He has evolved the following system, which he urgently advocates: First, a subcutaneous injection of .015 gm. morphin hydrochlorate during the first attack, or when first seen, repeated in one hour. The third hour a rectal injection of 2 or 3 gm. of chloral hydrate is administered and repeated the seventh hour. The thirteenth hour a similar rectal injection of 1.5 to 2.5 gm. chloral is given and repeated the twenty-first hour. The twenty-ninth hour another rectal injection of 1 to 2 gm. of chloral is administered and repeated the thirty-seventh and forty-fifth hours. If the comatose condition still continues with headache, especially if delivery is not terminated, the patient is still kept narcotized with small doses, .015 to .08 gm. of morphin and 4 gm chloral for the following twenty-four hours. Systematically proceeding in this manner, the recurrence of the attacks is prevented, and delivery occurs normally or can be hastened without danger to mother or child. His tabulated statistics show that the number of attacks in all his cases averaged only 2.4 to 3.3 per patient, while in other institutions they ranged from 6.9 to 9.5 during the same periods. He lays great stress on the importance of relieving the heart and lungs of every source of irritation—mechanical, physical or mental. The heart-action becomes very much depressed during an attack. Continuous reclining on the left side should not be allowed, nor even the pressure of the hand or arm on the heart or lung region. The clothing, blankets, or pillows should not be allowed to bind or weigh on the thorax in any way to impede the action of the heart or lungs. The mouth and nose must be kept free from obstruction from mucous. Fluids should be supplied by subcutaneous injection of 150 to 200 c.c. of salt solution or rectal injection of a litre in four or six parts during the day. Warm milk can be substituted for the salt solution in case of protracted eclampsia. Digitalis, inhalation of oxygen and other measures as indicated will also be found beneficial. The patient should be turned from the right to the left side and back again every hour or hour and a half, and other measures should be applied to loosen and favor the expulsion of mucous. If the lung symptoms become alarming and œdema is threatened, great

benefit can be derived from dry cupping. These minor points are all of great importance, but the chief aim in treatment is the suppression of the convulsions which can surely be accomplished by the system of administering morphia and chloral outlined above.

Arrested Labour from Distended Bladder in Fetus.

COUVEAIRE (*Bull. et Mem. de la Soc. Anat. de Paris.*) reports the delivery a little before term of a primipara, aged 24. Pregnancy had been normal. When she was admitted into hospital it was not certain how long the waters had escaped. There was slight albuminuria. The occiput presented to the right posteriorly, and there was some difficulty in delivering the head. Then the shoulders could not be extracted, even when the posterior arm was lowered. The child died during these manœuvres. The head midwife drew down the anterior arm, but the humerus was fractured and the shoulders remained fixed. On exploration the thorax appeared normal, but the abdomen was much swollen, and fixed above the pelvic inlet. The trocar was used, and 550 grams of fluid came away; it was clear, lemon-yellow in colour, and highly albuminous. Then the child was easily extracted. It weighed, excluding the urine already removed, over 6½ lbs., and measured 18½ inches; the biparietal measurement was 3½ inches. It was a female. The distention of the abdomen was due to retention of urine. The cause of the retention could not be detected; there was no malformation, and the urethra was quite free from stricture. The ureters and renal pelvis were dilated. GAUDON, CORNELLI, and LEFOUR have reported similar cases where no stricture existed. In PORAK's case the obstruction was due to a valvular fold in the mucous membrane, which HERGOTT of Nancy suspects must exist in all such cases, but is easy to overlook. As a rule retention of urine is due to complete congenital stricture.—*Brit. Med. Jour.*

Psychoses of the Menopause.

CHAPIN endeavours to show that the danger of insanity beginning during the menopause has been exaggerated. Out of 8,320 women admitted into various institutions, only 188 were specified as becoming insane at the menopause, nor was it clear how many out of the 188 went mad through the special changes in the genital tract at that period of life. The statistics of the Pennsylvania Hospital show that between the ages of 45 and 55, representing the usual range of the menopause, 975 men and only 876 women were admitted into that institution. S. WEIR MITCHELL, in his Analysis of 3,000 cases of melancholia, shows that the exact percentage of cases between the ages of 45 and 50 was 20·2 in men and 21·4 in women, the difference being very, very slight, and once more not due, on any distinct evidence, to the local changes of the menopause. The dread or risk of insanity at the approach of the menopause in a woman ordinarily of sound mental and physical health and inheritance has no better foundation than a popular delusion based on borrowed fears.—*Brit. Med. Jour.*

PHYSIOLOGY, PATHOLOGY, AND BACTERIOLOGY.

Cerebral Localization.

FROM the paper by SYDNEY KUH, in the *Journal of the American Medical Association*, reviewing the knowledge on this subject, the following points are gathered:—

Destruction of the prefrontal region is said to annihilate the power of directing one's attention entirely when the lesion is bilateral, while a unilateral lesion causes only a transitory mental change. Mental weakness, loss of memory and attention, apathy, and childish behaviour are common symptoms.

That cerebral centres may migrate from one side of the brain to the other was at least made probable by an observation of OPPENHEIM. His patient had been right-handed up to the age of seventeen, when an injury to the right hand compelled her to learn to write with the left one. When at the age of fifty-nine, a tumor developed in the right hemisphere; it caused left hemiparesis with aphasia.

Cerebral hemiplegia, whether it be due to a superficial or a deep-seated lesion, never means a complete paralysis of one-half of the body. Paralysis of cortical origin is flaccid in the beginning and presents late contractures due to secondary degeneration in the pyramidal tracts.

Monoplegias of the leg, which have been bilateral in a large percentage of cases, are explained by the close proximity of the two paracentral lobules.

Similarly, the immunity of the upper branch of the facial nerve in cerebral hemiplegia is given in explanation by the probable control exerted by each centre on both nerves, the muscles so supplied being among those generally used simultaneously on both halves of the body.

Centres for mastication and rotation of the head, located in animals, have not yet been satisfactorily determined in man.

While it may locate cortically the initial centre in true cases of JACKSONIAN epilepsy, not every localized spasm of organic nature may be regarded as conclusively cortical.

Valuable points in determining JACKSONIAN from idiopathic epilepsy are limited spasm at first, loss of consciousness late, if at all, epileptic cry, falling and biting tongue usually absent, post-epileptic coma slight and of short duration, etc.

Proliferation and Phagocytosis.

MALLORY first describes the different phagocytic actions observed from various infections, and in conclusion suggests the question whether the processes he has described are due directly to the action of toxins or reparative. In repair, cells proliferate for definite purposes—to cover denuded surfaces; to replace loss of tissue; form new blood-vessels, etc. The cells, however, which proliferate under the direct action of toxins multiply greatly in excess of need and show lack of definite purpose. They may exert some more or less beneficial action, possibly produce antitoxins, but they must not be regarded as reparative and may do great harm, block up lymphatics, produce necrosis, be carried to the liver as emboli and otherwise interfere with the organic economy. The phagocytic cells are phagocytic beyond all bounds of necessity and destroy great numbers of active, useful cells. They are all abnormal and, to a certain degree, malignant.

Bacteriological Diagnosis of Diphtheria.

DR. J. BRONSTEIN says (*Berlin. klin. Woch.*):—NEUSSER's staining method for the tinctorial differentiation of diphtheria bacilli and bacilli similar to them is not only of value for cultures, but also for smear preparations of diphtheritic membrane. Whenever bacilli containing stained granules were found in the pseudo-membrane, diphtheria bacilli were always found in the cultures made therefrom. It is advisable to stain for a longer time than is recommended by NEUSSER, that is, for half a minute with each of the two solutions. Distilled water is better for washing than ordinary water.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Infection from the Hands of Consumptives.

THE official bulletin of the State Board of Health, Maine, cites several instances in which tuberculous infection may be communicated by the hands. Experiments were made in the Adirondack Sanatorium to determine whether the hands of consumptives carry the bacillus of tuberculosis. The hands of only two out of ten patients in private practice were found free from infection, and those two persons were scrupulously careful by the use of cloths and cuspidors and frequent washing, to keep the hands perfectly clean. Two patients who only used handkerchiefs furnished an abundance of infection. These facts carry their own moral, and this one which may be commended to all who have charge of consumptive patients, or who live in close intercourse with such patients.—*Practitioner.*

Sanitation in the Home.

THE sanitary condition of the farm and country village house is often less carefully attended to than in large towns, because the system of plumbing and drainage compels the housewife in a city or town to live up to certain sanitary requirements, and necessitates a greater familiarity with the subject.

No matter how thoroughly a house and grounds were cleansed in the early spring, if they have not been properly cared for since, August is sure to find it beset with foes from without and within, for, in many respects, August and September are the most dangerous months of the year, and a most thorough inspection of the premises should be made, commencing at the cellar.

If this is dark and damp—and in city houses, where they are little used during the summer, even careful housewives are apt to neglect their ventilation—the foul air will permeate and make unhealthful the entire house. Throw open every door and window. If it was not given a coat of lime-wash in the spring, it should have one now; add to it a pound of copperas (in solution) as a disinfectant. Place open vessels containing copperas or charcoal in every dark corner, and see that the entire cellar is ventilated every day.

Every drain should be properly trapped, and the one connected with the kitchen sink should be provided with a grease-trap. But this does not lessen the housewife's responsibility to see that they are flushed with clear water every day and disinfected with chloride of lime, or scalding hot solution of washing soda, twice a week.

Carbolic acid is a better disinfectant for offal pails and water-closets; use in the proportion of one teaspoonful to a gallon of water. For an outside closet use lime, or dry earth, not sand, a little every day.

Next in importance to the disposition of sewage is that of the vegetable and other kitchen refuse. In large cities this is systematically gathered, and on a farm there are always animals who will eat it. When this is not the case, it should be burned in the kitchen stove, or in a weekly bonfire in the garden, or buried in a deep trench.

As you value the health of your family, never allow a pile of rubbish to accumulate in a corner of the garden, or behind an out-building, unless it is vegetable matter for a compost, and is made harmless by the frequent addition of earth, ashes, lime or copperas.

Never use wooden pails, or other receptacles for kitchen refuse, but galvanized iron, zinc, or tin, and see that they are thoroughly washed, scalded, and sundried at least every alternate day. The city housewife should use galvanized iron cans for garbage, and should sprinkle lime or copperas over the contents every day in hot weather, and thoroughly cleanse the cans whenever they are emptied.

Another frequent source of danger is the soiled clothing which awaits the weekly washing. Instead of being thoroughly aired and dried in the sun, and kept in a room remote from the bed-chambers and living rooms, it is thrown into a hamper kept standing in a bed-chamber, or in a pile in one corner of an adjoining closet, damp with poisonous exhalations from the body, and here the warmth of the room generates and throws off poisonous germs, which are inhaled by the occupants.

Every day the entire clothing should be removed from every bed that has been occupied, and, if possible, hung directly in the sun, the mattress turned, and the windows and blinds thrown open to admit the sun and pure air, and they should remain so at least two hours. In view of the care ordinarily given beds, and the garments worn during the night, one can only wonder that insomnia is not even more prevalent than it is.

Aride from the bed-chambers, every occupied room in a house should be disinfected every day by flooding it with sunshine and pure air. This done, with a clean, sweet cellar, and the attic windows open to give a free sweep of air at the top of the house, the rooms should be sweet, cool, and healthful.

Insurance Examiner's Knowledge of Prior Application.

AN applicant for fraternal benefit insurance, who warranted every statement made by him in his application to be true, stated therein that he had never before applied for membership in that order. The application was approved by the medical examiner-in-chief. But when suit was brought by the beneficiary to recover the insurance, the association set up a breach of warranty, and showed that about five years before the date of the application the insured had made a previous application to a different subordinate branch, and that such application had been rejected by the medical examiner-in-chief. To meet this line of defence, it was argued that the examiner-in-chief at the time he approved the application for the certificate in suit knew, or was chargeable with knowledge, of the prior application and rejection; that his knowledge was to be deemed the knowledge of the association; and that, therefore, the latter, having issued the certificate and received the assessments thereon with full knowledge of facts that would render it void, should not be permitted to defeat a recovery by proving such facts. This view was adopted by the trial court. The third appellate division of the Supreme Court of New York, however, rejects it, and reverses the judgment of the court below rendered in the beneficiary's favor. Even assuming that the medical examiner-in-chief knew, when he approved the second application, the circumstances of the previous transaction, the court holds, *Desmond v. Supreme Council, Catholic Benevolent Legion*, that his knowledge was not chargeable to the association, and that it had the right to avail itself of the defence of breach of warranty. Of course, it is left to be inferred, it might be otherwise, if his action had been more than a preliminary step in the transaction, and if it had been a part of his duty to issue or deliver the certificate.—*Jour. Amer. Med. Assoc.*

THERAPEUTICS & PHARMACOLOGY.

Intestinal Rest in Typhoid.

It is an axiomatic principle in both surgery and medicine that a congested or inflamed part needs rest.

The surgeon recognizes this when he immobilizes the fractured bone and retains the fragments in apposition; the physician likewise appreciates the great importance of this principle in cases of gastric ulcer when he feeds his patient by the rectum in order to avoid irritating the inflamed part either directly, or by exciting gastric motility. Although typhoid fever is essentially a systemic disease, its characteristic local lesion is the intestinal ulcer, which should, as far as possible, be kept at rest. Milk, which has heretofore been regarded as the only proper exclusive food, is, as a recent writer says, "not a liquid diet, but a deceptive solid"—capable of filling the small intestine with dense indigestible curds which scratch and irritate the ulcerated bowel, and in addition ferment and cause gaseous distention, tympanites, etc. Liquid peptonoids, on the other hand, is open to none of these objections. Its administration affords rest to the ulcerated intestinal tract, because:

1st.—It is predigested and therefore promptly absorbed from the stomach, leaving no residue for the bowel to dispose of.

2nd.—No curds are formed as from milk.

3rd.—It is absolutely aseptic and cannot cause fermentation, tympanites or increased peristalsis, resulting in diarrhoea.

4th.—It has the requisite nutritive power to maintain life for weeks and even months, especially in febrile conditions.

Another advantage of liquid peptonoids is its palatability, which renders it grateful to the patient, especially when given for food.

From one to two tablespoonfuls every two, three or four hours should be given as necessary. When an efficient intestinal antiseptic is required, as it very frequently is in this disease, liquid peptonoids with cresote provides both food and remedy at one and the same time. The unpleasant taste of the cresote is almost entirely abolished in this combination. Each tablespoonful contains two minims of pure beechwood cresote and one minim of guaiacol, its active principle.

Hypodermic Injections of Campher in Phthisis.

ALEXANDER (*Munch. Med. Woch.*) claims further good results from his method of injecting hypodermically the camphorated oil of the German pharmacopoeia, which contains 0.1 gm. of campher in each cubic centimetre (*Review*). Campher has a cumulative action, and may produce nervous disturbances, especially if pyrexia is present. He now, therefore, employs very small doses. When pyrexia is present, the quantity of oil injected daily should correspond to $\frac{1}{4}$ gr. or at most $\frac{1}{2}$ gr. The treatment can be continued uninterruptedly for weeks or months. In apyretic cases the same treatment may be adopted, or larger doses of campher, such as 1½ gr., may be given daily for four days at a time, and resumed after an interval of at least eight days. Campher given by the mouth causes anorexia, sweating, and cough.

VON CRINGEN (*Berlin. Klin. Woch.*) employed ALEXANDER's method for two years among the out-patients of the district polyclinic at Leipzig. He concludes that the treatment has no influence whatever on early cases of phthisis before the process of ulceration and breaking down has begun. He reaches conclusions which show that in the second stage, contrary to ALEXANDER's statement, the campher tends to induce hæmoptysis. In five cases slight hæmoptysis followed every injection, but did not occur when they were omitted. The injections were, however, useful in advanced cases in which cavities were present. They relieved the general prostration and enabled the patients to do more work. Though ALEXANDER claims that campher relieves insomnia, VON CRINGEN says it has no influence on sleep. Neither has it any sedative effect on pain, dyspnoea, or cough, though night sweats are sometimes lessened by it. The indications for the use of campher are therefore identical with those for the use of balsamic and mucous substances. The contraindications are also identical—renal disease and a tendency to hæmoptysis. The injections are frequently painful.

Value of Rest in Bed in the Treatment of Certain Digestive Disorders.

ALLEN draws attention to the frequency with which anaesthesia, anæmia, and malnutrition are associated, and the great amount of injury to the system at large that may be produced by such a triad. The deficiency in nerve energy and the consequent imperfect innervation of the tissues lead to a general lack of muscular tone, which finds expression in different ways according to the region of the body affected. In the abdomen the general relaxation has for its consequences visceroptosis and stony of the stomach and intestines with their attendant evils, and in proportion as the lack of proper nutrition increases the somatic weakness, the debilitating events move in a vicious circle of greater and greater circumference and constantly involve more remote regions in the disease. Under such conditions the evident indications are rest and feeding. But to be properly effective the patient must completely change his previous faulty mode of life and be treated in a wholly alien environment. As a routine for such cases, at least three weeks of absolute rest in bed, in some institution away from home, is to be advised, together with a full diet, for even though the state of the stomach may seem to contraindicate this over-feeding, in most cases it will relieve the symptoms more quickly than the most carefully adjusted, but quantitatively insufficient, régime. By these means bodily waste of all sorts, nerve and muscle, is reduced to a minimum, and the depleted cells are enabled to regain their normal tone and vigor.—*Zeitschrift für Krankenpflege*.

Indications for the Use of Gastric Lavage.

(1) To remove undigested food and foreign matters; (2) to cleanse the mucous membrane for the action of medicines; (3) to check hæmorrhage; (4) to give antiseptic douchings; (5) for sedative purposes; (6) for general tonic effects upon the gastric mucous membrane and paretics.—DR. J. M. G. CARTER, *Medical Fortnightly*.

For Nutritive Enemas after Abdominal Section.

Correspondence.

PURE DRINKING WATER.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—There is no lack of beliefs and traditions in India about water, showing that the people have thought about it and do believe in different qualities possessed by water that may be beneficial or otherwise. But unfortunately their ideas are mostly wrong, and they cause infinite mischief at times to the people.

Water from the sacred rivers—Ganges, Jumna, Godavari, and others—are reported to remain sweet when bottled for an indefinite period. This is an excellent test even if it lasts only a few days; but although it may have been true at some remote period, it cannot be true now, as these rivers receive the sewage of every town on their banks, and in the dry season the water of the Ganges below Cawnpore smells strongly of sewage that is discharged by two large and very foul sewers. It is open to any one to bottle some of this water for a week by way of experiment, but nobody does it—unless he be a sanitary official.

There is a current tradition that living (flowing) water purifies itself, however foul it may be. This is a half truth that is very misleading. A river will purify itself of sewage, but only after many miles of flow, but those people who bathe in a stream in which putrifying corpses lie only a few yards away above them, and who wash their mouths and even drink the water, should not be surprised if they are ill afterwards. There are hot springs in various parts of this country renowned for their curative properties, and there are wells in many places whose water is said to be better and more wholesome than other water; but the numerous devices the Indians have for defiling their sources of water-supply may be taken as a proof of a national indifference to really pure water. There are many wells in Guzerat that have each cost a lakh and upwards of rupees, approached by magnificent flights of steps, and decorated story after story downward with elaborate stone carvings. These wells have springs at a depth which should give perfect water-supplies, were it not that the men and women descend the steps with bare feet that have traversed streets and alleys, and after taking their supply of water they wash their feet and mouths and even spit in the water. When it rains, all the accumulated dirt on the steps is washed into the well, forming in course of years a deposit of very unwholesome mud at the bottom. Now and then a woman will drown herself in the well, but no cleansing process follows after the removal of the body.

The belief that wells should be open to the sun and air has much to answer for, and offers a very striking

commentary on a people who claim to have produced so many profound thinkers. In hill districts, where water issues from holes in the hillside, everyone knows that the best and cleanest water is to be had just where the water issues from the earth. If the spring is at the bottom of a well, the same rule ought to hold good; but, on the contrary, an opposite opinion prevails. The water is allowed every opportunity of defilement before it is drawn from the well. Trees overhang it and drop in sticks and leaves. Birds build their nests in crevices and add to the defilement. The wind blows dust of all kinds into the well, and the cords and vessels used by the people to draw their supplies are liable to many kinds of infection. No public drinking well in India can be safe from becoming a source of infection of cholera. It all depends on the chance of a single infected vessel or rope being dipped once in the water. Nothing but centuries of habit could reconcile any people to the habit of drinking water from a tank that is daily used for bathing by cattle and by men, as such is the case all over India. If this water is filtered, the process is only a mechanical one that does not touch the dissolved impurities. A rag (not always clean) and a layer of sand will only separate soiled matter. Occasionally chunks of wool about the size of the size of rod metal. These are quite useless, as the water passes between them and remains unaffected. Even if a European filter be used by the educated native, it will be generally found out of order and badly in need of a new charge. The Indian hotel-keeper always has a filter, and it is generally a fraud. Last May one hotel at Mahabeshwar had a filter through which water was daily passed for consumption. A visitor observing the very bad state of the drinking water insisted on seeing the inside of this filter. He found the carbon block lying loose in the upper chamber; the plug had been lost. In another hotel the English filter was filled with lumps of charcoal from the kitchen. A third hotel had excellent filters which were always in good order, but the Bishop's Well, the best reputed source of domestic supply on the hill, was in a shocking condition. The sand filter seemed not to have been cleaned since it was built.

All over India the intelligent observer may see examples of wanton neglect of precautions, which, if taken, would ensure a much more wholesome water-supply. The Muhammadan conquerors were much more careful in the construction of their wells than the Hindus, but as they had a habit of constructing deep cesspits in the vicinity of their wells, contamination from below neutralised all the precautions they took to keep the mouth of their wells closed. Ahmedabad, until the water-works were constructed, depended to a large

extent on wells that were contaminated with sewage. Although the natives of India are so reckless in allowing their source of drinking water to be polluted, they are continually using precautions to protect themselves from impurity. No trouble is too great in carrying out this duty. There are many reasons to suppose that in knowledge of practical hygiene the Indians have degenerated during recent centuries as they have in the industrial and the fine arts. Their customs of frequent bathing, the tradition that running water purifies itself, their precautions regarding their food, their mode of raising water from wells economically, all appear to date from a period of enlightenment that is now forgotten. It is therefore not a question of introducing new and foreign habits, but rather of returning to old and good customs of practical cleanliness that we advocate—customs that will commend themselves to all intelligent men, and will reduce the high death-rate that prevails generally in India.

Yours, etc.,

SANITARY ENGINEER.

THE INEFFICIENCY OF THE INDIAN MEDICAL SERVICE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—As a civilian medical practitioner of many years' experience in India, it appears to me that in it you have undoubtedly hit the right nail on the head when you suggest that apparently the only remedy is to separate the Civil from the Military branches of that service. Presumably, when men join the Indian Medical Service, they do so as Army surgeons, but as soon as they can possibly do so, they, for obvious reasons, take up civil work. Now, Sir, the question comes to be—is this the best training these men can get for work at the front? I fear not, as the majority of them, when they become civil surgeons, almost forget the fact that they are military men, and simply become civil practitioners, this being more particularly the case in the mofussil; and when in cases of emergency they are called back to military service, they must, I should imagine, feel like fish out of water. I believe the only remedy for this would be to form a separate Civil Medical Service for India, and confine the attention of the members of the Indian Medical Service to military work. The idea of bringing out medical men from home to act temporarily during these emergencies is not, I think, by any means a good one, as the terms offered by Government to men to fill these temporary appointments are quite inadequate to tempt good men to come out and fill them; and, added to this, there is the extremely unsettling effect a residence of a year or two in India has

on a man, especially a medical man. If, on the other hand, a new Civil Medical Service were formed, with a pension attached after a certain number of years' service, I am perfectly convinced that Government would have no difficulty in getting the right sort of men to join, as many who would object to joining the Indian Medical Service, on account of its being a military service, would join the service I suggest. Another point to be noticed in this connection is that, if the members of the I. M. S. were forbidden to take up private practice, numbers of private practitioners would set up on their own account in the large towns in India—as indeed a large number have already done. Judging from what we hear of the frightful congestion in the medical profession at home, and the enormous number of men who are year by year passing out from the various medical schools, I can't imagine there would be much difficulty in recruiting both the Indian Medical Service and the new service I suggest. The only other alternative would be to double the strength of the present I. M. S., which, I imagine, would be a very much more costly matter than establishing a new service on the lines I suggested.

Yours, &c.,
ÆSCULAPIUS.

DEALERS AND BUYERS OF BOGUS AMERICAN DIPLOMAS: ANOTHER EXPOSURE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—Your thorough exposure of the bogus American degrees in the *Indian Medical Record* is highly interesting. I can give you some information in this connection which may be useful to you. Babu BHUBAN MOHAN BANERJI, M. A., LL. D., the successful agent of the "Western University," is a translator in the Original Side of the Calcutta High Court. He lives in Bhoom Ghose's Lane, off Cornwallis Street. He has a brother—MAHENDRA NATH BANERJI—a man without any education, general or medical. This is Dr. M. N. BANERJI, M. D., the "consulting physician" attached to a dispensary named "Hahnemann's Home," in College Street at Bowbazar. He goes about in European dress and imposes on the credulous as a real medical man. Both the astute brothers are holders of American degrees.

It may interest you to know that the bogus degrees are not confined to the medical profession. A pleader of the Calcutta High Court, Babu SURENDRA NATH GHOSAL, residing at Bhowanipore, has recently imported an American degree in Law, LL. D., purporting to be from "Universitas Occidentalis." It is significant that this man is a relative of the brothers BANERJI.

In any investigation which you may be advised to make, I shall be ever ready to render you every assistance that lies in my power.

Yours, &c.,
ENQUIRER.

(We have already forwarded this information officially to the Commissioner of Police, and we trust that excellent official will do his duty in this matter.—ED., I. M. R.)

Government Medical Gazettes.

BENGAL.

Asst. Surgn. Akshoy Kumar Mukherjee did suppy. duty at the Dacca Mitford Hosp. from the 12th to the 23rd Nov. 1900.

Asst. Surgn. Akshoy Kumar Mukherjee's apptd. to act at the Meherpur Subdivn. and Dispy., in the Nadia dist., from the 25th Nov. 1900, during the absence, on leave, of Asst. Surgn. Kristo Charan Bose.

Asst. Surgn. Abinash Chandra Bandyopadhyay is apptd. tempy. to the Cholera Emigration Hosp. at Nalhati from the 18th Nov. 1900.

Asst. Surgn. Abinash Chandra Bandyopadhyay did suppy. duty at the Med. Col. Hosp., Calcutta, from the 27th Oct. to the 11th Nov. 1900.

The services of Lieut.-Col. R. N. Campbell, M.B., I.M.S. (Bengal), are placed at the disposal of the Govt. of Bengal.

The services of the undermentioned offrs. are placed tempy. at the disposal of the Milly. Dept. :—

Maj. Narendra Prasanna Sinha, I.M.S. (Bengal); Maj. R. J. Marks, I.M.S. (Bengal); Capt. H. Ainsworth, M.B., I.M.S. (Bengal); Capt. A. N. Fleming, M.B., I.M.S. (Madras); Lieut. J. L. Marjoribanks, M.B., I.M.S.

On relinquishing ch. of the civil med. duties of the Amritsar Dist., Capt. A. W. T. Buist, I.M.S., Civil Surgn., is posted to Gurdaspur as Plague Med. Offr. from the 16th Nov. 1900.

Asst. Surgn. Thakur Kedar Nath, in ch. of the Munaffargarh Dispy., officiated as Civil Surgn. of that sta., in addn. to his own duties, from the 8th to the 15th Nov. 1900.

PUNJAB.

Hosp. Asst. Mussaddi Mal, doing gen. duty at Hissar, was apptd. on itinerant duty in that dist. from the 16th Oct. 1900, *vice* 3rd Class Hosp. Asst. Sheikh Ahmad, who was placed on gen. duty at Hissar from the same date up to the 31st Oct. 1900, when he retired from the service.

Hosp. Asst. Brij Lal, doing gen. duty at Hissar, was apptd. on itinerant duty in that dist. from the 1st Nov. 1900, *vice* 1st Class Hosp. Asst. Mussaddi Mal, who was permitted to retire from the service.

On being relieved of the tempy. ch. of the Bewari Dispy., Gurgaon Dist., Asst. Surgn. Parmansand was placed on gen. duty at Delhi on the 14th Nov. 1900.

Hosp. Asst. Ali Ahmad was apptd. to do gen. duty at Jullundur on the 14th Nov. 1900.

Hosp. Asst. Karam Chand, Punjab Luthatic Asylum Hosp., has obtained one month's privilege leave, and was relieved of his duties on the 4th Nov. 1900 by Hosp. Asst. Bansil Lal, doing gen. duty at Lahore.

On being relieved of his duties on the Chenab Canal, Lyallpur Divn., Hosp. Asst. Iram Din was apptd. to the ch. of the Tochi Valley Dispy., Miranshah, on the 23rd Oct. 1900, *vice* Hosp. Asst. Aulad Hussain, who was granted one month's privilege leave.

Hosp. Asst. Diwan Chand, doing gen. duty at Umballa, was apptd. to the ch. of the Mooltan-Sidhnai Canal Dispy., Kakharhatti, from the 24th Oct. 1900, *vice* Hosp. Asst. Thandee Ram, who was placed under suspension from the 21st Oct. 1900.

Hosp. Asst. Thandee Ram, under suspension, was dismissed from the service of Govt. from the 14th Nov. 1900.

Hosp. Asst. Sheikh Abdullah Travelling Hosp. Asst., N.W. Ry., Lahore Sec., was granted one month's privilege leave from the 1st Oct. 1900.

Hosp. Asst. Sheikh Abdullah rejoined his duties on the N.W. Ry., Lahore Sec., on the 31st Oct. 1900, relieving Hosp. Asst. Kale Khan.

On being relieved of the ch. of the Gobana Dispy., Rohtak Dist., Hosp. Asst. Muzraiz Khan was transferred to the Upper Sutlej Inundation Canal from the 23rd Sept. 1900, and relieved Hosp. Asst. Khada Baksh on the 30th Sept. 1900.

Asst. Surgn. Ramji Lal, doing gen. duty at the Mayo Hosp., Lahore, was transferred to the ch. of the Hissar Dispy. on the 18th Nov. 1900, relieving tempy. Asst. Surgn. Thakur Das.

1st Class Hosp. Asst. Kale Khan, doing gen. duty at Wazirabad, Gujranwala Dist., was transferred to Lahore for gen. duty on the 18th Nov. 1900.

Asst. Surgn. Abdul Aziz was apptd. to do gen. duty at Amritsar from the 6th Oct. 1900.

Asst. Surgn. Jugal Kishore was apptd. to do gen. duty at the Bupar Dispy., Umballa Dist., on the 11th Oct. 1900.

Asst. Surgn. Jugal Kishore, doing gen. duty at the Bupar Dispy., Umballa Dist., was apptd. to the ch. of that institution from the 18th Oct. 1900, relieving Asst. Surgn. Mala Ram.

Hosp. Asst. Zulficar, Ajnala Dispy., Amritsar Dist., has obtained privilege leave for three months, and was relieved of his duties on the 15th Nov. 1900 by Hosp. Asst. Muhammad Shafi, transferred from gen. duty, Amritsar.

Hosp. Asst. Baber Khan, doing gen. duty at Umballa, was apptd. to the ch. of the Jail Hosp., Amritsar, on the 12th Oct. 1900, *vice* Hosp. Asst. Abdulla Khan, who was granted privilege leave for 25 days from the 1st Oct. 1900.

Hosp. Asst. Abdulla Khan rejoined the Jail Hosp., Amritsar, on the 25th Oct. 1900, relieving Hosp. Asst. Baber Khan, who was placed on gen. duty at that sta.

On the termination of his itinerant duty in the Jullundur Dist., Hosp. Asst. Bindraban was placed on gen. duty at the Civil Hosp., Jullundur, on the 16th Nov. 1900.

Asst. Surgn. Maya Das held ch. of the current duties of Supdt. of the Mooltan Dist. Jail from the 6th to the 15th Nov. 1900, both days inclusive, during the absence of Maj. D. M. Davidson, M.D., I. M. S., on inspection duty in the dist.

Capt. A. W. T. Buist, I. M. S., made over ch. of the duties of Supdt. of the Amritsar Jail to Senior Asst. Surgn. Mehr Chand, Rai Bahadur, on the 12th Nov. 1900.

Senior Asst. Surgn. Mehr Chand, Rai Bahadur, made over ch. of the duties of Supdt. of the Amritsar Jail to Lieut.-Col. T. R. Mulroney, M.D., I. M. S., on the 18th Nov. 1900.

Capt. C. H. James, I. M. S., made over ch. of the duties of Supdt. of the Umballa Jail to Asst. Surgn. Krishen Chand on the 20th Nov. 1900.

The undermentioned gentleman is apptd. a non-official visitor of the Sialkot Jail, *vice* Sardar Udharn Singh Chhabbi, who has left the station :—

Mr. Joseph Greenwood, Secretary, Dist. Board, Sialkot.

Capt. J. Stephenson, I. M. S., made over ch. of the duties of Supdt. of the Peshawar Jail to Lieut. W. H. C. Forster, I. M. S., on the 29th Aug. 1900.

Lieut. W. H. C. Forster, I. M. S., made over ch. of the duties of Supdt. of the Peshawar Jail to Lieut. W. J. Keen, B.C.S., Asst. Commr., on the 4th Sept. 1900.

Consequent on his return from furlough on med. certificate, Lieut.-Col. T. R. Mulroney, I. M. S., Civil Surgn., 2nd class, is promoted to the 1st class with effect from the 13th Nov. 1900, and Lieut.-Col. S. Little, I. M. S., Civil Surgn., 1st class, is reverted to the 2nd class.

On return from privilege leave Lieut. J. F. Weston, Senior Asst. Surgn., resumed ch. of the duties of Civil Surgn., Hissar, on the 8th Decem. 1900, relieving Asst. Surgn. Jowahir Singh.

Asst. Surgn. Feroz-ud-din, doing gen. duty at the Ferozepore Civil Hosp., was apptd. as a tempy. arrangement to the ch. of the Umballa Civil Hosp. on the 22nd Nov. 1900, relieving Asst. Surgn. Krishen Chand.

Asst. Surgn. Muhammad Hussain did gen. duty at the Mayo Hospital, Lahore, from the 28th Sept. to the 3rd Oct. 1900.

The services of Hosp. Asst. Abdul Wahab Soffy, doing gen. duty at Karnal, were placed at the disposal of the Govt. of India, Foreign Dept., for employment in the Somali Coast Protectorate from the 21st Nov. 1900.

On being relieved of the ch. of the Rohtak Dispy., Hosp. Asst. Bukn-ud-din was transferred to Ludhiana for gen. duty on the 30th Oct. 1900.

Hosp. Asst. Baka-ud-din, doing gen. duty at Ludhiana, was apptd. to the ch. of the Ludhiana Police Hosp. from the 18th Nov. 1900, relieving Hosp. Asst. Feroze-ud-din, who reverted to gen. duty in the Ludhiana Jail.

Asst. Surgn. Khazan Chand resumed ch. of the Civil Hosp., Sialkot, on the 23rd Nov. 1900, relieving Asst. Surgn. Abdul Aziz, who was placed on gen. duty at that institution.

On being relieved of the tempy. ch. of the Khewra Dispy., Jhelum Dist., Hosp. Asst. Baber Khan reverted to gen. duty, Amritsar, on the 10th Nov. 1900.

Hosp. Asst. Baber Khan, doing gen. duty at Amritsar, was granted two months' privilege leave from the 12th Nov. 1900.

Asst. Surgn. Umrao Raja Lal, doing gen. duty at Karnal, was granted one month's privilege leave from the 18th Nov. 1900.

Hosp. Asst. Hara-ud-din, doing cholera duty in the Dera Ghazi Khan Dist., was apptd. to the Lalgarh Dispy. in the same dist. on the 13th Nov. 1900, relieving Hosp. Asst. Sham Lal.

On being relieved of the ch. of the Lalgarh Dispy., Dera Ghazi Khan Dist., Hosp. Asst. Sham Lal reverted to the ch. of the Police Hosp., Dera Ghazi Khan, on the 20th Nov. 1900, relieving Hosp. Asst. Vasu Ram, Dera Ghazi Khan Jail Hosp., of the additional ch.

On being relieved of the ch. of the Ludhiana Civil Hosp., Asst. Surgn. Udal Bhan, Imperial List, was deputed tempy. for plague duty in the Jullundur Dist. on the 19th Nov. 1900.

Hosp. Asst. Imam-ud-din resumed ch. of the Attock Dispy., Hazara Dist., and med. ch. of the Look-up, on the 28th Nov. 1900, relieving Hosp. Asst. Jaggan Nath.

The undermentioned Hosp. Assts. were transferred for special plague duty in the Gurdaspur Dist. from the stns. and on the dates noted against their names:—

Amar Singh, cholera duty, Gurdaspur Dist., 31st Oct.; Sultan Ali, gen. duty, Batala, 4th Nov.; Harbhagwan Das, plague duty, Jullundur Dist., 18th Nov.; Muhammad Rafik, plague duty, Jullundur Dist., 18th Nov.; Goverdhan Das, plague duty, Jullundur Dist., 18th Nov. 1900.

The following Asst. Surgns. were transferred for special plague duty in the Gurdaspur Dist. from the stns. and on the dates noted against their names:—

Vidy Nath Singh, plague duty, Jullundur Dist., 14th Nov.; Tempy. Asst. Surgn. Thakur Das, Hissar Dispy., 20th Nov. 1900.

Hosp. Asst. Feroze-ud-din, doing gen. duty at the Ludhiana Jail, was apptd. as a tempy. measure to the ch. of the Ludhiana Police Hosp. on the 14th Nov. 1900, relieving Hosp. Asst. Abdul Rahman.

The following Hosp. Assts. were transferred for plague duty in the Jullundur Dist. from the stns. and on the dates noted against their names:—

Abdul Rahman, Police Hosp., Ludhiana, 15th Nov.; Permeshri Das, gen. duty, Jullundur, 21st Nov.; Lekh Nath, gen. duty, Shahpur, 22nd Nov. 1900.

Hosp. Asst. Faqir Chand, doing gen. duty at Gujrat, was placed under suspension without allowances for the 1st and 2nd Nov. 1900. He was released from suspension from the latter date and placed on gen. duty at Gujrat.

On the termination of his special plague duty in the Jullundur Dist., Hosp. Asst. Asa Ram reverted to the Montgomery Dist., and was apptd. to the ch. of the Shah Niwaz Dispy. on the 30th July 1900.

Hosp. Asst. Shankar Das, doing gen. duty at Shahpur, was transferred to the Jhelum Canal on the 12th Nov. 1900, and relieved Hosp. Asst. Ghulam Hussain of the Canal Dispy., Ala, on the 15th Nov. 1900.

Hosp. Asst. Ghulam Hussain was granted privilege leave for two months from the latter date.

Hosp. Asst. Hovan Das resumed ch. of the Shabkadr Dispy., Ferozepur Dist., on the 4th Dec. 1900, relieving Hosp. Asst. Nawab Ali.

Hosp. Asst. Abdulla Khan, Arnauli Dispy., Karnal Dist., was placed under suspension, without allowances, from the 2nd to 21st Nov. 1900. He was released from suspension on the latter date, when he rejoined his dispy.

The services of Hosp. Asst. Abdul Hamid being no longer required for itinerant duty in the Umballa City, he was placed on gen. duty at the Civil Hosp., Umballa, on the 7th Dec. 1900.

Hosp. Asst. Ghulam Haider, doing gen. duty at Jhelum, was apptd. to do gen. duty at Rawalpindi from the 5th Dec. 1900.

Hosp. Asst. Mirza Imdad Beg, Police Hosp., Rawalpindi, has obtained three months' privilege leave, and was relieved of his duties on the 9th Dec. 1900 by Hosp. Asst. Ghulam Haider, doing gen. duty at Rawalpindi.

Hosp. Asst. Wasfi Ibrahim did gen. duty at the Simla Jail Hosp. from the 27th Sept. to the 5th Oct. 1900.

Asst. Surgn. Jogendra Nath Biswas, in med. ch. of the Native Establishments attached to the Govt. of India Secretariate, Simla, was granted three months' privilege leave from the 6th Dec. 1900.

Asst. Surgn. Asghar Ali resumed ch. of the Chinist Dispy., Jhang Dist., on the 17th Nov. 1900, relieving Tempy. Asst. Surgn. Uttam Chand.

Hosp. Asst. Aulad Hussain, doing gen. duty at Sialkot, was placed on plague duty in the Sialkot and Gurdaspur Dist., from the 8th Dec. 1900.

Hosp. Asst. Kale Khan, at present attached to the Hoshiarpur Police Hosp., was reduced to the 2nd class of Hosp. Asst. from the 1st Sept. to the 3rd Dec. 1900.

BOMBAY.

The Governor in Council is pleased to appoint Dr. E. H. Moore, on relief of his duties as Dist. Med. Offr., Khandesh, to be Dist. Med. Offr. under the Famine Code for the dist. of Bijapur.

Asst. Surgn. Ramchandra Shivaji Poredi, L. M. & S., has been apptd. to the med. ch. of the Malegaon Dispy. from the 5th Dec. 1900.

Asst. Surgn. Rastamji Jamshedji Petigara, L. M. & S., has been apptd. Teacher in the Med. School, Hyderabad, from the 2nd Dec. 1900.

BURMA.

Asst. Surgn. F. X. DeAttaides having qualified himself for promotion to the next higher grade, is entitled to the pay and allowances of the 1st grade from the 2nd June 1901.

The following Hosp. Assts. having qualified for promotion to the next higher grade, are entitled to the pay and allowances of that grade from the date noted against them:—

Hosp. Asst. Kutbuddin—promoted to 1st grade from the 15th April 1901; Hosp. Asst. Shaik Abdul Aziz—promoted to second grade from the 4th August 1901.

Hosp. Asst. Daulat Ram availed himself of the leave granted him from the 30th Nov. 1900.

The leave granted to Hosp. Asst. Mazhar Ally is commuted into leave on med. certificate and further extended by two months.

Hosp. Asst. S. Bastian relinquished ch. at the Police Hosp., Kundat, Upper Chindwin dist., on the 31st Oct. 1900, and assumed ch. at the Police Hosp., Falam, Chin Hills, on the 15th Nov. 1900.

Hosp. Assts. Naziruddin Ahmed and Abdul Karim assumed ch. at the Police Hosp., Bhamo, on the 5th Dec. 1900.

Hosp. Asst. Hem Chandra Koyal relinquished ch. at the Police Hosp., Bhamo, on the 4th Dec. 1900, and assumed ch. at the Outpost Hosp., Warabum, Bhamo dist., on the 8th Dec. 1900.

Hosp. Asst. Andrew Po Saw assumed ch. at the Civil Dispy., Yenangyaung, Magwe dist., on the 5th Dec. 1900.

Hosp. Asst. A. B. Mukerji relinquished ch. of his duties with the Bassein-Henzada Ry. Construction at Bassein on the 5th Nov. 1900, and assumed ch. at the Outpost Hosp., Nampaung, Bhamo dist., on the 19th Nov. 1900.

DOMESTIC OCCURRENCE.

ORIGINAL ARTICLES.

METHODS OF TEACHING GYNÆCOLOGY.

BY HOWARD A. KELLY, M.D.,

Baltimore, Md., U.S.A.

Professor of Gynecology in the Johns Hopkins University.

THE question as to the best methods of teaching any particular branch of our art is always one of burning interest, which should command the serious attention of teachers everywhere. Such a topic is also especially timely at this juncture, inasmuch as while, on the one hand, gynecology has now been taught regularly in various schools for a quarter of a century or more, and the methods of teaching gynecology have largely settled into well-defined rut, on the other hand the evolution of scientific pedagogy has in the same period taken remarkable strides. It behoves all teachers, therefore, to question their systems and to decide whether they are really advancing on the best lines, in accord with what is recognised as good teaching in schools and colleges.

I believe that gynecology is, as a rule, very badly taught, and the medical student gains but little from this part of his course. This fact would be evident at once to anyone familiar with thorough scientific methods of teaching employed in other departments; but, unfortunately, the object-lessons of this sort in America are still few and far between.

Before we can decide what are the best methods of teaching gynecology, we must consider a few of the difficulties in the way of securing anything like a consensus of opinion among the teachers.

And the first of these difficulties lies in the fact that so many schools have reorganised their plans of instruction in extending the two-year course to one of three years, and others the three-year course to four.

Advanced as the University of Pennsylvania has ever been in the lines of medical instruction, my own class was the first which graduated as a class with three years of compulsory study. As a rule, the professor of gynecology, continuing on from the old system into the new, made no corresponding change in his method of teaching to meet the altered conditions.

Another even more serious difficulty, and one which will, I believe, in the end swamp gynecology as a specialty in the sense in which it has been practised, is the encroachments of the general surgeon in the field of abdominal surgery, leaving the gynecologist no particular settled ground which he can consider as peculiarly his own. It is foreign to my purpose to consider this question here, or to assume the prophetic role; but I may briefly state my conviction that the unification of surgery brought about by the general adoption of the principles of asepsis leaves the barrier between general surgery and gynecology a purely artificial one, and one which must inevitably, sooner or later, be broken down. My advice, therefore, to all gynecologists is to study general surgery and become general surgeons first.

Three classes of men come to me for instruction in gynecology, and I feel obliged to provide to the best of my ability for each. They are:—

I. Students preparing for graduation.

II. Post-graduate students re-visiting schools for better equipment.

III. Graduates desiring to become specialists.

1. Students preparing to take the degree of Doctor of Medicine. How much should a student know at graduation? or how little may he know?

I think the tendency of most of our schools is to give entirely too much instruction in this purely special branch. One year's instruction is ample, even in a course graduated to extend over four years. This leaves the student free to devote more time to the fundamental branches and laboratory courses in general medicine and in the principles of surgery.

But few students ever become gynecologists, and it is a waste of valuable time to treat the whole class as if they were working with this end in view. I shall refer later to the training necessary to build up a specialist.

In the last year, when medical specialties are taken up in the natural order after a thorough preliminary training in the fundamental branches, from three to four hours a week may be devoted to the class in gynecology, divided as follows:—

1. History-taking and ward work, attending to dressings and removing sutures, and studying the sequels of operations, the convalescence.

2. A touch course once a week in which gynecological diagnosis is taught with the patient preferably under anaesthesia.

3. An hour a week in the pathological laboratory studying scrapings and cultures and examining gross specimens.

4. Watching gynecological operations, the class divided into small sections.

5. Lectures.

I think the day for teaching gynecology by performing operations in an amphitheatre before a large class of students has long since gone by. The students see practically nothing of what is going on, absolutely nothing in a deep, abdominal, or vaginal operation, and their very presence is a serious menace to the life of a patient.

The history taking, the ward work, the touch course, all of which demand personal instruction, are the most valuable methods, bringing student and patient together, as they must meet in the natural course of events after graduation, and carrying the student up to the point beyond which he will not be apt to go, that is, up to the point of deciding upon the line of surgical treatment to be followed.

It must be borne in mind that, with our present conception, gynecology is essentially a surgical specialty, and making a diagnosis of a gynecological affection means, as a rule, an operation, while, with the vaguer methods of diagnosis of our predecessors, the very uncertainty allowed delay for weeks or months, during which time all sorts of so-called palliatives were employed—a line of treatment easily carried out by the general practitioner. I well remember the first instructions I had in a special course, when all I learned was

to give the woman much pain by the examination, and to paint the vault of the vagina with CHURCHILL'S dis-
 ture of iodine in one case, and the next woman, without
 rhyme or reason for the change, with a carbolic acid
 and chloral mixture, and so on *ad infinitum*, completing
 each treatment with a ball of absorbent cotton. Many
 were the cases of "cellulitis" which owed their origin
 to such a course of treatment, associated with "intra-
 uterine applications."

I cannot dismiss the touch course without urging
 that the number who make the examination should be
 limited to several working under the watchful eye of
 the teacher, lest harm be done.

The early recognition of cancer as taught by the study
 of endometrial and cervical scrapings in the laboratory
 (perhaps the most important function of the teacher
 of gynecology) constitutes a leading feature in my
 own teaching as ably conducted by Dr. THOMAS S. CULLEN.

The use made of the lecture-room should depend
 upon the lecturer; if he is an inspiring teacher, who well
 comprehends the modern definition of a teacher, not as
 one who talks volubly, but as "one who causes another to
 know," he may make his lectures, associated with demon-
 strations and specimens, diagrams and lantern-slides, a
 great attraction to the students. If he is a poor, dry
 talker, he would better relegate this part of his work to a
 good quiz master, and confine himself to the more practical
 lines of teaching.

"Seeing operations," especially the major gynecologi-
 cal operations, is perhaps the most abused of all methods
 of teaching. It is utterly useless for the student to see
 over and over again a hysterectomy or an ovariectomy
 which he will never do himself, and which, if he did
 attempt to do, it would be of but slight service in mak-
 ing him a safe operator. What he most needs to see
 repeatedly are the various minor operations which he
 may have to do, such as curettage and suture of the
 relaxed vaginal outlet.

It may be more convenient and profitable to divide the
 class into small sections, and to double or even treble the
 amount of instruction in a given space of time. This
 involves repetition with each succeeding group, but it
 saturates the students for the time being with the sub-
 ject and brings them individually closer to their work.

II. The plan of teaching for post-graduates must, as
 far as practicable, imitate the laboratory methods so
 widely used in other departments. Lecturing must be
 subordinated to demonstrations *in anima vivâ*. The place
 of the lecture is a short informal talk about topics with
 which the hearers are not likely to be familiar, which are
 about to be demonstrated in practice.

The operator will then do well as he goes along in
 his practical work at the operating table if he remem-
 bers the needs of the by-standers and tells them from
 time to time precisely what he is doing, and his reasons
 for doing it.

I do not consider it right, in the interests of the
 patient, to utilize men who enter a clinic for a few weeks
 only as assistants in important operations.

Unfortunately, too, for the same reason (the patient's
 rights), only a limited number can be allowed to examine
 the patient beforehand. The surgeon must try to sup-
 ply this want as far as possible by giving graphically
 both the history and results of his own examination.

A great need which we feel most keenly in this country
 is that of female cadavers enough to supply the demand
 for special dissections and for demonstrating operations
 to both students and post-graduates. An abundant sup-
 ply of such material would greatly enrich our teaching
 facilities.

It is my own custom to receive post-graduates as on-
 lookers at any time in the course, and for any period,
 to provide for them abundant demonstrations of the
 various gynecological operations, and an opportunity to
 study scrapings in the pathological laboratory.

III. I come now finally to a class which I think has
 not yet received sufficient attention in other clinics—
 a class, however, which I am personally inclined to
 regard as really the most important of all to us teachers,
 that is to say, those men who are to be built up to
 become specialists in gynecology. In order to train a
 man this way, the chief must be careful to select men
 who have real surgical ability; he must keep them for
 periods of from four to six or even eight years; they
 must receive exceptional opportunities in the operating-
 room (some of my assistants perform upwards of two
 hundred abdominal operations while acting as first and
 second assistants in the hospital). The chief must treat
 his capable men with the utmost generosity in this particu-
 lar.

He must further supervise the development of a good
 man in his laboratory work, in his ward work, and in his
 teaching, and finally often end by sending him abroad to
 give him that assurance in his own powers which often
 only comes after witnessing the work of others. One
 of the greatest pleasures of my life has come from the
 association through a period of years, with just such men
 who have afterwards gone elsewhere to render distin-
 guished services.

The man who in this way looks not only to his own
 success, but endeavors to stimulate and to develop others,
 much as he would himself have wished to have been
 treated early in his career, will not only command the
 respect of his own generation, but will surely be reckoned
 by the men who follow him among those who have done
 the most to promote the best interests of his specialty.

The following is a summary of the course in gynecology
 as conducted for under-graduates in the John Hopkins
 University and Hospital.

At the Johns Hopkins Medical School the fourth-year
 class is divided into four sections, each of which devotes
 a large portion of its time for two months in turn to
 practical work in medicine, surgery, gynecology, and
 obstetrics, while in all those subjects lectures and quizzes
 are given to the whole class throughout the year.

The graduating class of last June numbered about 40.

The instruction in gynecology during the university
 year 1899-1900 was conducted as follows:—

Lectures.—In gynaecology, two didactic lectures were delivered each week to the fourth-year students. Dr. KELLY lectured once a week, and Dr. RUSSELL once, and between them the whole range of the subject was gone over.

The lectures were illustrated by blackboard sketches, diagrams, pathological specimens, and, whenever practicable, by the demonstration of cases. Quizzes were occasionally substituted for the lectures, in order that the instructors might keep informed as to the students' progress.

Clinics.—Dr. KELLY operated three days a week throughout the year, and Dr. RUSSELL one day.

The operating room was open to as many of the class as cared to attend, and the gynaecological section was required to be present.

Before and during the operation the cases were discussed, opportunity given for a limited number of the students to make examinations under ether, and so arrive at their own diagnosis.

Special care was taken to impress the students during the operation with the importance of careful aseptic technique.

Ward Work.—To each member of the gynaecological group several cases in the public wards were assigned during their two months' service.

The students took the histories of these cases, made the examinations under the supervision of the resident, witnessed the operation, and followed the after-treatment progress of their cases.

Rounds were made with the gynaecological group by the resident twice a week, during which dressings were made, and the reasons for the treatment adopted explained.

Touch Course.—Once a week throughout the year a "touch course" was conducted by Dr. RUSSELL. Here from three to six dispensary patients, whose condition without an anæsthetic was uncertain, were carefully examined under ether by two to four members of the gynaecologic section, who made their diagnosis under Dr. RUSSELL's direction. This course has for years proved of the greatest service to students.

Experience has shown that it was better for all concerned that the gynaecological dispensary be conducted by a limited number of experienced men; hence this department has not been opened to the under-graduates.

Pathology.—For four months during the year a course in gynaecological pathology was conducted by Dr. CULLEN.

After an introductory lecture at each exercise, sections were given out for microscopic study. Whenever possible, the history of the patient, the operative interference, and the subsequent treatment were reviewed, while the preparations were being examined and demonstrated under the microscope. The pathological laboratory was open throughout the year for any student who cared to carry out original investigations.

Examination.—At the close of the term a final examination, both practical and written, was held, covering the work of the year.

FOUR CASES OF DIABETES MELLITUS OF APPARENT BACTERIAL ORIGIN, AND THEIR SUCCESSFUL TREATMENT.

By J. P. SHERIDAN, M. D.

In the latter part of 1898, a writer in the *New York Medical Record* related his experience with bichloride of mercury in the treatment of diabetes mellitus, and advanced the novel theory of the bacterial origin of this affection.

At the time of publication of the article in question, I had some diabetics under treatment. As a moderately rigid anti-diabetic diet and the time-honored remedies did not check the glycosuria in my patients, I adopted the newly proffered theory, and eagerly prescribed the advocated chemical.

To-day, after a year's trial of germicidal remedies in diabetes, I have become a firm believer in the bacterial origin of diabetes. It is true the bichloride of mercury did not prove a success in my hands, but this only tends to demonstrate the existence of a peculiar diabetic toxine, which has to be combated by other means. This toxine, in my opinion, is particularly apt to attack the nervous matter, which in turn gives rise to the well-known disturbance of metabolism in diabetes—namely, preventing the deposition of glycogen in the liver and muscles, and causing its discharge by the kidneys in the form of grape sugar. The irritation of the vasomotor centres, to which may be attributed all the symptoms of diabetes, seems to be caused by this toxine. It is plainly the physician's duty to eliminate the toxic influences, for he thereby relieves the irritation of the nervous centres. However, he must be most careful in the selection of the proper remedy, and in the administration of its indicated dose. The failures in diabetic therapy have to be ascribed either to a wrong medicine, or its improper administration, or to both. The ideal anti-diabetic drug should not only exert distinct germicidal and antiseptic powers, but should be a powerful alterative. At the same time the system should not become weakened and emaciated by its prolonged administration. On the contrary, the ideal diabetic remedy should afford great tonic properties.

Bichloride of mercury and auri et sodii chloridum, which latter is so much lauded of late by a Chicago physician, possess some of these desiderata; but neither proved of any success in my hands in the treatment of diabetes mellitus. This non-success is due to three factors:—

A. The specific toxine of diabetes is affected only by a specific antiseptic.

B. Bichloride of mercury or auri et sodii chloridum, when pushed to their physiological tolerance, do not effect the decline of the glycosuria.

C. Bichloride of mercury as well as chloride of gold and sodium, when administered for any length of time and in larger doses, reduce the oxidising power of the red blood cells, thereby weakening the system and producing rapid emaciation.

The remedy answering all the demands for an ideal anti-diabetic I find in a combination of bromide of gold

with bromide of arsenic, called by its makers "arsenauro." This preparation undoubtedly exerts a specific influence upon the bacteria and the toxine of diabetes mellitus, which is elucidated by the following four cases:—

Case I.—Mr. C. L., aged fifty, American, clerk, consulted me on June 8th, 1898. Family history was negative. Patient complained of polyuria, the existence of which dated back about three months. The frequency in urination he thought to be due to a stricture, the possible result of a neglected gonorrhoea. Patient had a moderate appetite, felt quite thirsty at times, and had lost some weight. The urine (which was voided to the amount of about seven pints daily) on June 10th, 1898, showed a specific gravity of 1.038, and contained 7.1 per cent. of sugar, as ascertained by means of STERN'S urinoglucometer. A restricted diet and the administration of codeine caused only a moderate improvement of the symptoms. Bichloride of mercury, which was given for the last three weeks of December 1898, in the doses recommended, not only produced no beneficial influence whatsoever upon the diabetic condition, but actually aggravated the condition of the patient. Early in July 1898 my attention was drawn to the chloride of gold and sodium, which was handed to the patient in tablet form and administered first in doses of a fiftieth of a grain. The dose was gradually increased to a twentieth of a grain. After five weeks' trial of this drug it had to be abandoned, as the condition of the patient had become alarming in the meantime.

At about this period I ran across an article in the *New York Medical Journal* regarding the use of arsenauo in diabetes and determined to test this product, having previously used it with satisfactory results in malarial toxæmia.

On February 7th, 1899, eight drops of arsenauo were given in half a glass of water three times daily. The restricted diet was ordered to be continued. Patient reported to me in one week. The glycosuria and polyuria were greatly diminished. The feeling of thirst was not experienced any longer, and he expressed himself as feeling perfectly well. The dose of arsenauo was gradually increased until he reached his full limit of toleration, which supervened at fifty drops. The quantity was lessened to forty-five drops, and continued in this dose for sixteen weeks. After this period I examined the urine, which revealed a specific gravity of 1.020, and was absolutely free of sugar. Patient was discharged as cured, with the instruction to continue the arsenauo for at least six months.

Case II.—M. H., a woman, aged thirty-four, American, unmarried, came to consult me September 11th, 1898. July previous, during the hot spell, she perspired greatly and suffered from excessive thirst. Her weight, which normally was a hundred and sixty-five pounds, had diminished to a hundred and thirty-five pounds. Frequent micturition was distressing her greatly. Appetite was voracious for some time, and her strength gradually declined. When first seen by me, the daily quantity of her urine amounted to eight pints. Specific gravity 1.046; sugar 7.538 grains a day. She complained of incessant thirst, inordinate appetite, pain in back, and extreme feebleness.

She was put on a restricted diet on September 20th, but no medication given her. Patient improved somewhat, but not sufficiently. In December 1898, bichloride of mercury was given, and the same diet continued without effecting any noticeable change in the patient's condition. In February 1899 she was put on arsenauo, and the same diet still continued. The medicine was started in eight-drop doses three times daily, to be taken in a glassful of Vichy water. Ten days after great improvement had taken place. The urine became reduced to forty-nine ounces, specific gravity 1.028, and the sugar output to two hundred and ten grains in twenty-four hours. After this the dose of arsenauo was gradually increased until the patient reached her full physiological limit; this took place at forty-drop doses—that is, after the administration of two drachms a day. Patient was instructed to occasionally discontinue the administration of the remedy for twenty-four hours, and then to start again on thirty-five drops.

This latter dose was taken for some months, with the result of rendering the urine entirely free of sugar. She was advised to continue with the medicine for at least six months longer. I examined her urine of late, and found it absolutely normal and free of sugar.

Case III.—H. E. B., a man, aged thirty-seven, American, railroad conductor, consulted me in March 1899 on account of an irritable bladder. Patient was compelled to urinate quite frequently during the day as well as during the night. His other symptoms left no doubt as to his real affection—diabetes mellitus. The disease, so far as I could ascertain, dated back for about a year, and seemed to be devoid of further complications. The quantity of urine voided varied from twelve to fifteen pints a day, with an average specific gravity of 1.042. Sugar averaged four thousand grains for the twenty-four hours. The treatment consisted in restriction of diet and the administration of arsenauo, ten drops of which were ordered to be taken in half a goblet of water three times a day. This dose was gradually increased until patient took sixty drops three times daily. When this quantity, three drachms, was taken every day, the patient's lids began to puff and his bowels became loose and caused griping. The medicine was discontinued for twenty-four hours, but again ordered to be taken in fifty-five-drop doses. Patient had taken the fifty-five-drop doses for eight weeks, when I again examined his urine, which contained only a trace of sugar. One month later he was perfectly well, and all vesical irritation had disappeared—in fact, I pronounced him well. I advised patient to report to me from time to time, but to continue the arsenauo for at least six months.

Case IV.—B. R., aged forty-seven, a woman, unmarried, American, milliner, thin and emaciated, able to attend to her business, consulted me April 12th, 1899. Patient complained of great weakness, which had gradually increased for several months. She had excessive thirst and had voided a greatly increased quantity of urine, but her appetite was moderate. Her skin was dry and she complained of intense pains in the calves of her legs, especially in the morning. There was distressing pruritus vulvæ present. The specimen of urine sent to me for

examination presented a specific gravity of 1.045 and contained 8.1 per cent. of sugar. I restricted the patient's diet as to starches and sugar and placed her at once on ten-drop doses of arsenauo, to be taken in a half tumblerful of water three times daily. After one week the dose of arsenauo was increased three drops every day until she reached its toleration. Physiological saturation was obtained when forty-five drops were taken three times a day. The administration of the remedy was then stopped (as I am in the habit of doing) for twenty-four hours, after the lapse of which it was again ordered to be taken in forty-drop doses. This dose was kept up for six weeks. On July 3d she had gained seven pounds in weight; uranalysis demonstrated entire absence of sugar; the pruritus had entirely disappeared, and there were no evidences whatsoever of symptoms pertaining to diabetes mellitus. Patient was advised to continue the medication for at least another six months.

The four cases which so readily yielded to this anti-toxic treatment were apparently of bacterial origin. Arsenauo, by saturating the system, arrested bacterial activity, or killed the germs, or neutralized their toxins. However, only by saturation with the proper medicine—and, by the way, arsenauo is the only powerful alternative neutralizer which can be pushed to an almost incredible dose without doing bodily harm—can such results as are recorded in the foregoing be obtained.

SEXUAL IRRITABILITY IN THE MALE.

By A. SANDNER, M.D., M.R.C.S., ENG., L.R.C.P., LOND.,
Chicago, Ill., U. S. A.

No other morbid condition has proved so rich a harvest for the quack on the one hand, and so humiliating to the honest practitioner on the other, than the one with which, in my opinion, about twenty-five per cent. of young men in this country are at some time or another of their adolescent years affected—sexual irritability. I have treated, and am treating now, cases to which numbers of reputable members of the profession have repeatedly stated that there is nothing the matter with them, and have found them in a really pitiable condition. What is the reason for such action? I can only explain it by a mistaken modesty of the attending physician, for I cannot for a moment believe that ignorance of the necessary sequelæ is the real cause of the neglect. In a certain number of cases—those resulting from gonorrhœa—the tendency to use too many of the new remedies without paying proper attention to the dilution and application of them may account for some of the ill-results. Now, I am not for standstill, but I believe in giving preference to, and retaining, well-approved and efficacious remedies and methods; and while I do not believe in a physician adopting a routine treatment for a certain malady, I think it is well to have a well-tested outline of treatment at hand for ready reference. The application of experimental methods in private practice is detrimental to the reputation of the family physician.

When considering the prophylaxis and treatment of a disease, we must first have a definite idea as to its

etiology, for it is impossible to avoid and counteract unknown causes. The subjects of our discussion can readily be divided into three distinct etiological categories.

The first class of patients belong to the lithemic type. They are, as a rule, blondes, with blue eyes, flabby muscular tissue, and large stature, and look, according to the laity, the picture of health. But their assimilative power is so ill-balanced that the slightest indiscretion in regard to the consumption of nitrogenous food and malt liquors will cause an irritation of the urinary apparatus. It matters little whether we believe with GARROD that the nervous system is too weak to control the conversion of uric acid into the soluble sodium urate, or agree with LUFF that the kidneys neglect to perform this duty; the fact remains that large quantities of insoluble urates are eliminated whenever the slightest disturbance of the digestive function occurs. With those periodical eliminations an irritation of the urinary tract, and, during adolescent years, of the sexual apparatus, concurs, causing frequent and painful micturition and nocturnal emissions, with their sequelæ, which latter are not intended to be discussed in this paper.

The second class is the nervous type. They are rather thin, mentally active, are inclined to great variation of emotional excitement, and, as a rule, of dark complexion. Their nervous system has outgrown their physical constitution. Like every other impulse of their unstable nervous system, the sexual desire becomes an uncontrollable factor, and masturbation or excessive venery is resorted to.

The third class is the one whose sexual irritability can be traced to an antecedent attack of gonorrhœa.

It is only purposed to discuss the management of these cases up to when they have resulted in an inflammation of the prostate (veru montanum) and the seminal vesicles, but it is desirable to know the different course these three varieties run if left to themselves, or if improperly treated.

In the first class the sexual symptoms are obliterated after a while by the urinary troubles; the patient becomes a renal invalid. In the second the patient is considered "hysterical," and later "neurasthenic," with the adjective "sexual" if the true cause be recognised, and he has to bear all the miseries those constitutions entail. The subsequent history of the third class may include all possible sequelæ of gonorrhœa.

The greatest benefit to the first and second classes of these patients results from a knowledge of hygienic and dietetic means suitable to their respective conditions. The first requisite is a moderate and regulated amount of exercise. These patients should not be tired out, but they should enjoy at least two hours per day of exercise, preferably walking, in the open air. The lithemic patient can even perform more laborious tasks without any injurious consequences, but the nervous patient is better off if he takes everything, muscular as well as mental work, in a quiet and leisurely manner. I am thoroughly convinced that a good deal of nervous irritability is kept up with these patients by the excitement incidental to some games—football, for instance—whereas the lithemic, frequently melancholy inclined individual,

can hardly get exhilarated with any game; the reaction following muscular overstrain in the neurasthenic is sometimes just as depressing as a severe mental effort. It is by no means always an easy task to restore the patient's emotional equilibrium, but by proper moral support and auxiliary medicinal measures, a great deal of good can be accomplished.

The diet of the lithemic must consist of fruits and green vegetables, spinach being the best, mainly, and he should be very particular to avoid too much meat, coffee and alcohol. Such vague injunctions as "eat a light supper" should not form a part of the dietetic instruction to these patients, for the youthful possessor of a gouty constitution has inherited a desire for large meals, and has a far different idea of a light supper than the instructor. Fish and poultry should be substituted for meat, weak tea for coffee and buttermilk, or a little whisky in lemonade, if absolute abstinence cannot be practised for malt liquors and other alcoholic drinks. Eggs may be allowed in moderation. With the neurasthenic a nourishing and supporting diet is indicated. The heaviest meal should be the midday dinner, the supper consisting only of tea, bread and butter and fruit.

The medicinal treatment indicated in the first class resolves itself in the eliminative and supporting. As far as the former is concerned, I am strongly opposed to the customary Epsom salts and iron for pelvic congestion, for in my experience Epsom salts rather increases the supply of blood to the pelvic organs, and iron is generally not well borne by gouty subjects. I have had good results from—

R	Sodii et Pot. Tartar 2 ounces.
	Potass. Tartras. Acid 1 ounce.

M. Sig. One teaspoonful in a tumblerful of hot water every morning.

Plenty of fresh water is an excellent adjuvant. Another good remedy is LAMBERT'S Lithiated Hydrangea, one teaspoonful, freely diluted, twice daily. It combines a solvent effect upon the gouty deposits with a slightly laxative action. As a hematinic I use enemas of saline solution, one teaspoonful of salt to a pint of hot water, one-half to one pint every evening. Syrup calcii lactophosphate two drachms in one ounce of water, three times daily, is another suitable tonic.

In the neurasthenic it is of the utmost importance to allay the sexual passion. This may be accomplished by one-half to one drachm doses of fluid extract of *salix nigra* one-half hour before retiring. To build up the jaded nervous system I have obtained good results from arsenic in the following combination:

R	Sol. Fowler's ...	1 to 1½ drachms.
	Ext. Ergotæ ...	fl 3 drachms.
	Tr. Capsici 10 minims.
	Glycerini 1 ounce.
	Aque ...	q. s. ad 8 ounces.

M. Sig. One tablespoonful three times daily after meals.

Of nothing I am more certain than that a great deal of harm is done by the too frequent resort to local treatment. The passage of the sound I hold to be particularly injurious. The pathological condition is an inflammation of the prostate and seminal vesicles, and the only admissible local interference consists in the expression of the irritating secretion from these parts.

If I have spoken rather dogmatically about the classification of the etiological varieties, I wish it to be understood that I did so for the purpose of demonstration only, and that combinations exist which will only be brought to a successful issue by the proper discrimination of the attending physician. The prophylaxis of the third class of cases consists in the proper treatment of gonorrhœa, and I shall take leave to discuss this subject at some future occasion.

A MIRROR OF PRACTICE.

OVARIAN TUMOUR IN A GIRL THIRTEEN YEARS OLD: OPERATION: RECOVERY.

(REPORTED BY MISS K. BONNAR, L. M. S.),

Grigg Female Hospital, Barabanki.

KASALI, a Hindoo girl, aged 13 years, was admitted into the Grigg Female Hospital, Barabanki, on December 13th, 1900, with an abdominal tumour and symptoms of dyspepsia.

Personal History.—She is unmarried, and has never menstruated. There is no history of any serious previous illness.

Present Illness.—The patient states, and the statement is corroborated by the father, that four years ago she had an acute attack of colic, from which she recovered, but it was the beginning of a series of similar attacks, each one more severe than the last: abdominal massage generally relieved her. A week or two after the first seizure of pain she noticed a small tumour in the lower part of the abdomen, which gradually reached the size of a large marsh melon. The severity of the colic pains forced her to seek relief in hospital.

Present Condition.—The patient is fairly well developed and in fairly good condition: there is no marked emaciation, anæmia or any other indication of interference with nutrition. In the lower part of the abdomen below the umbilicus, and almost in middle line is a well-defined globular freely moveable tumour, the upper part of which is on a level with the umbilicus. It is dull on percussion, and has a distinct fluid thrill. It is not tender to the touch, its position is not influenced much by posture, and not at all by respiration. The only subjective symptoms complained of were pain and uneasiness in the epigastrium after food. The tongue was coated.

Diagnosis.—It was considered that the tumour was either an ovarian or one connected with the mesentery. It was decided that an operation was the only means of curing the girl of this tumour, and the consent of the patient and of the father having been obtained, preparations were made for the operation. On the day previous to the operation she had a soap and water bath and a change of clothes. The abdomen was washed with turpentine and covered with a pad of muslin soaked in perchloride lotion 1:2000. Castor-oil 3ii was given at night. On the morning of the operation, i.e. December 17th, a soap and water enema was given and then change of clothes. The instruments used were boiled and then put into carbolic lotion 1:20. A few minutes before the operation they were taken out and put in salt solution grs. 5 to 3i. Chinese twist was also boiled and put in carbolic lotion 1:20. Muslin pads 8" x 8", six folds each, were prepared for use as sponges, the muslin having previously been soaked in perchloride lotion 1:2000. The hands of the operator and assistants were first soaked in CONDY'S fluid and then in a solution of oxalic acid. Everything having been got ready, the patient was put on the table and the bladder relieved by means of a catheter. Chloroform having been administered, the abdo-

men was again washed with carbolic lotion 1:20. An incision was then made 2" long by Dr. M. N. OHDEDAR, and all bleeding points having been secured by SPENCER-WELLS' pressure forceps, the peritoneum was carefully opened, and two fingers introduced to explore the nature of the tumour. It was found that it was an ovarian tumour springing from the left side, and that the intestines were extensively adherent to it, especially towards the back. The incision was then enlarged upwards, and the anterior surface of the tumour made to present through the incision. An ordinary trocar cannula in the absence of SPENCER-WELLS' trocar were pushed in. On removing the trocar, about 25 ozs. of chocolate-coloured fluid came out. The tumour was then pulled out and several coils of small intestines which were adherent to it came out also. It was noticed that on account of these adhesions the complete removal of the tumour was impossible. The pedicle was then ligatured, and as much of the tumour as could safely be done was removed. About a fifth of the wall of the tumour was left adherent to the intestines as a permanent appendage. It was thoroughly scraped. The abdominal cavity was then flushed out with sterilised water. All fluid, especially from the DOUGLAS' pouch, was carefully removed by means of the muslin pads, one bleeding point was ligatured with catgut. The edges of the abdominal wound were then brought together carefully by means of deep silk-worm guts and superficial horse-hair sutures. The silk-worm sutures, which were six in number, were passed through the entire thickness of the abdominal wall, including the peritoneum. The wound was then dusted with iodoform, four folds of ALENSBROTH gauze and a pad of antiseptic cotton were laid on and secured by means of a broad bandage. That patient bore the operation well.

After-treatment.—For the first twenty-four hours after operation the patient was given nothing, though she complained of thirst. Urine was drawn off by a catheter every twelve hours. The evening temperature was 99.4°.

The next morning the temperature was normal, though the patient complained of some pain in the wound. Half a teaspoonful of milk and an equal quantity of soda-water were given every hour. Both in the morning and evening the temperature remained normal.

On the third day the quantity of soda-water and milk was increased, and from the fourth day BRAND's essence of chicken, a teaspoonful at a time, was given every hour, besides milk and soda in the morning and evening. On the fifth day she passed urine without the aid of a catheter.

On the sixth day, as the bowels had not acted, a plain hot water enema, 10 ozs., was given much against the patient's wishes. She fretted much and this caused a rise in temperature; in the evening the thermometer registering 99.8. The bowels were relieved, and from the next day she was allowed dal and rice cooked very soft, besides a tin of BRAND's essence of chicken per day. Beyond the rise in the temperature on the two occasions mentioned, she made an uninterrupted recovery, and

the sutures were removed on the tenth day. The wound healed by first intention. Fresh dressings were put on, and the patient being anxious to return home was allowed to leave the hospital on January 3rd, 1901—the eighteenth day after operation.

INTRAPERITONEAL RUPTURE OF THE BLADDER: OPERATION FOUR DAYS AFTER INJURY: RECOVERY.

BY W. PERCY BLUMER, F. R. C. S., EDIN.,

Surgeon to the Sunderland Infirmary.

J. P. B., labourer, single, aged 35, was admitted into the Sunderland Infirmary at 1.30 P. M. on August 2nd, 1900, complaining of pain in the abdomen and inability to pass urine.

History.—On the evening of July 29th, while walking along a street, he was seized with a feeling of giddiness and fell, striking his abdomen on the kerbstone. On recovery, he felt little the worse for his accident, and walked home. On reaching home he discovered that all attempts at micturition were fruitless; there was, however, a slight escape of what he took to be blood. On July 30th he stayed in bed and sent for a doctor, who prescribed a pill and saw him only once. He remained in bed till August 2nd, and feeling no better, walked to the infirmary, a distance of over two miles. He had been drinking heavily just before his accident, and said his bladder was full at the time.

Condition on Examination.—The abdomen was greatly distended all over, somewhat tender on palpation, and absolutely dull in both flanks and across the abdomen to little above the umbilicus. There was no extravasation into the perineum. Hiccough was constant and distressing; this had been the case for the three days prior to admission. He appeared very ill; the face was pale and drawn, with sunken eyes. No food had been taken, except milk and water, since the accident. Pulse 60 per minute, regular and fairly full. Temperature 96° F.

A soft rubber catheter passed easily, and immediately bloody urine flowed, 196 ounces in all being drawn out (quantity carefully measured). The abdomen thereafter resumed a more normal appearance. There was no doubt as to the nature of the injury.

Operation.—Laparotomy was performed at 4 P. M. with the assistance of Mr. T. F. HOGGOOD. The patient having been put under chloroform, an incision was made in the middle line just above the pubis, and the abdominal cavity entered in the usual way. A quantity of fluid similar in character to that previously drawn off flowed out. The bladder was lightly contracted, and showed a vertical tear on the posterior wall, which admitted two fingers easily, the peritoneum covering its wall being torn an inch lower down. There was no peritonitis.

The rent was closed with continuous sutures, the bladder tested, the abdominal cavity flushed out with hot boracic solution and the abdominal wound stitched up, a KEITH's drainage tube being inserted, and a soft catheter tied into the bladder.

After-history.—The tube was exhausted one hour afterwards (fluid $\frac{1}{2}$ ounce), then again in two hours (fluid 1 ounce). Thereafter exhaustion was made every four hours. The tube was withdrawn at the end of forty-eight hours, and the opening closed with a flying suture.

On the evening of August 5th the patient became very noisy and restless, attempting to get out of bed, pulling out the catheter and threatening the nurses; he suffered also from slight hallucinations. A hypodermic injection of morphine, $\frac{1}{4}$ grain, followed by $\frac{1}{4}$ grain one hour later, had the effect of quieting him, and that night he slept better. On August 6th he was quiet, and slept seven hours.

On August 7th, when dressing the wound, the lower stitches appeared very tense, and on cutting two drachms or so of pus, and what was evidently urine, escaped. The opening was syringed with 1 in 5000 corrosive solution and drained with iodoform gauze. That evening a consultation was held as to the advisability of opening up the abdominal wound; it was, however, deemed inexpedient on account of the sloughing state of the tissues and the almost entire absence of symptoms of peritonitis. A fine rubber drainage tube was inserted instead of the iodoform gauze, and hot boracic fomentations applied every two hours. A seidlitz powder was administered.

There was evidently a little leakage from the bladder, and small quantities of urine continued to flow through the tube in the abdominal wall, the channel being cut off from the general peritoneal cavity.

The remaining stitches were taken out on the tenth day, when the whole length of the wound burst open, and a large slough was taken out. The urine was now very alkaline. On August 9th, 99 ounces of urine were secreted in the twenty-four hours. The bladder was syringed out with boracic lotion, and boracic acid, 10 grains, was given thrice daily. This treatment was continued for ten days, after which salol was administered in 5-grain doses every two hours, in place of boracic acid, up to 60 grains in the day. Under this treatment the cystitis rapidly yielded.

The temperature was generally subnormal for the first ten days, but on the third and tenth days it reached 99° F. On the sixteenth and twenty-first days it reached 101° F. It then fell to normal, and remained so until the end.

The fistula was rather slow in healing, but the patient was discharged quite well on October 29th. During the last week of his convalescence he had three epileptic fits of a transitory nature.

Remarks.—I have not been able to find on record such a case. The points calling for special mention are—

1. The length of time between the injury and operation.
2. The large amount of fluid in the abdomen causing comparatively little trouble.
3. That four days after the injury the patient walked over two miles.
4. The absence of symptoms of peritonitis.

I am indebted to Dr. C. G. WERRINGSPOON, house surgeon, for the notes of this case. His care and attention materially contributed to the patient's recovery.

NOTES ON A CASE OF PROFUSE HYDROPERITONEUM * TONEUM COMPLICATING UTERINE FIBROIDS.

BY A. C. BUTLER-SMYTHE, F.R.C.S., EDIN.,

Surgeon to the Samaritan Free Hospital for Women and Children, and to the Grosvenor Hospital for Women and Children, Westminster.

In abdominal surgery one frequently meets with cases in which uterine fibroids are accompanied by varying quantities of hydroperitoneum, the amount seeming to depend more on the mobility of the growth than on its size. Instances of profuse hydroperitoneum occurring in patients free from thoracic or other abdominal disease are, however, uncommon, and therefore I have ventured to publish this case.

Mrs. T., aged 40, consulted me in December 1895 on account of an abdominal swelling.

History.—She had been married seventeen years and had had three children, the youngest being then 14 years of age. Menstruation began at 15, and her periods had always been regular and painless, the loes being free and the flow lasting usually seven days. Her last period had occurred in November 1895. In her early life she had had the usual minor ailments, and after marriage pneumonia. She had also two attacks of influenza. Six months previous to her visit to me she experienced some abdominal pain, and later on a swelling was noticed in her right side. This swelling seemed to become bigger before each period, and in the intervals it decreased in size. Of late she suffered from constipation, and there were symptoms of bladder pressure. There had been no loss of flesh within the last six months, her weight being now 8 st. 11 lb. Up to December she had enjoyed good health, and was well able to attend to her business and household duties.

Condition when first seen.—Medium height, pallid features, skin moist, tongue clean, pulse regular and of fair volume, temperature normal, respirations natural, slight hæmic murmur at base, but otherwise the heart seems healthy, bowels constipated, urine free from albumen and sugar, liver normal. Bimanual examination revealed two moveable tumours in the abdomen—one situated in the right iliac and lumbar regions, the other occupying the hypogastric and left iliac regions. Pressure on one or both of the tumours was communicated to the uterus, showing them to be closely connected with that organ. The cervix uteri was hard and granular, the os patulous, and the uterine cavity measured 3½ inches. The diagnosis arrived at was "subperitoneal uterine fibroids," and it was agreed that operative interference was uncalled for in the absence of severe symptoms. The patient was therefore put upon ergot and iron, and advised to live frugally, avoiding wines, and stimulating diet.

Progress.—The patient remained in fair health until August 1896, when she had an attack of peritonitis, and in my absence from town consulted Sir SPENCER WELLS, and later on Mr. ALBAN DORAN, both of whom advised against operative measures. During the following ten months she had little to complain of, and continued at

her business, being able to take long walks and look after her house. On June 28th, however, she met with an accident, being knocked down by a cart when crossing the road. She was much bruised on the abdomen, thighs, legs, and arms, and narrowly escaped being killed. The accident was followed by abdominal pain, and from that date she rapidly lost ground.

Repeated Aspirations.—The tumours became tender, emaciation was marked, and on August 24th free fluid was detected in the abdomen. By September 13th she was much distended, and 18 pints of clear amber-coloured fluid were removed by aspiration. On September 24th she was again relieved, 20 pints being withdrawn. At the end of two weeks, on October 6th, the aspirator was again necessary, and about 20 pints were evacuated. On October 25th the patient was admitted into the Grosvenor Hospital for Women, Westminster, and two days later she was for the fourth time aspirated, 21 pints being removed. The re-accumulation of fluid, however, was so rapid that on November 2nd about 14 pints were taken away.

Operation.—The patient now decided to have the tumours removed. Accordingly, on November 6th, I operated. On opening the abdomen about a gallon and a half of fluid escaped. The parietal peritoneum was unusually thick and injected. The omentum was adherent to the parietes and also to the anterior surfaces of both tumours. There was much intestinal adhesion, the cæcum and appendix cæci having to be dissected off the lower part of the right tumour before it could be brought outside the abdomen. The *serre-naud* was then placed in position, and the operation completed. Chiefly owing to the extent of intestinal adhesions the operation occupied two hours, and the patient when put to bed was in a very collapsed condition.

Recovery.—She rallied steadily and made a good recovery. There has been no return of the hydroperitoneum, and at the present time the patient enjoys the best of health.

To my mind it is clear that the hydroperitoneum was directly caused by the injury to the peritoneum covering the fibroids, inasmuch as up to the date of the accident the patient was in very fair health, whereas all the bad symptoms rapidly developed after the injury, and were at once relieved, and the patient cured by the removal of the uterus and tumours. The following points seem to me to be worthy of consideration, and may be of interest to my hearers:—

1. The ovaries and tubes were healthy.
2. The tumours removed were simple fibromyomata, and showed no signs of malignant or other degeneration, but the peritoneum covering them was thick and injected. The tumours were not oedematous.
3. Up to the date of the accident no free fluid had been detected, and there was no loss of weight.
4. Emaciation was first noticed, and free fluid in the abdomen first detected about six weeks after the accident.
5. So far as could be ascertained, the patient was free from thoracic or abdominal disease.
6. Though aspiration had to be performed five times in six weeks, and about 20 pints of fluid were evacuated each time, yet there was no re-accumulation of fluid after the supra-vaginal hysterectomy, and the patient remains in perfect health.

Indian Medical Record.

30th January 1901.

THE DEATH OF OUR BELOVED QUEEN.

"HER MOST GRACIOUS MAJESTY THE QUEEN IS DEAD"—Such was the sad message flashed from London to all the ends of the earth, when at Osborne, at 6-30 P. M. on Tuesday, the 22nd January, the Queen-Empress breathed her last and fell asleep in death. That fervent, soul-stirring prayer of a nation and an Empire—

"God save our Gracious Queen,
"Long live our Noble Queen,
"God save our Queen.
"Send Her victorious,
"Happy and glorious,
"Long to reign over us,
"God save our Queen."

will no more be sung. But how thankfully and reverently should every British heart acknowledge that never was prayer more fully answered. Long life and reign, "victorious, happy and glorious," beyond comparison in history, has been, and is, the record of an unblemished, ideal, queenly life. It were vain to dwell at length on such a record in a medical journal. Authors, poets, orators, journalists of the highest order in every realm and in every clime, will recite and indite the story of the life of Victoria, the Great, the Good. We only venture to express the deep sorrow of every heart in this Empire, the genuine and poignant grief of every member of our profession, for the great and inestimable loss which every subject of the world-wide British Empire now suffers by this dread calamity. The Victorian era has been one of "victorious and glorious" triumph for the peaceful and gigantic strides of medical science, not more in any country than in Britain and in India. Side by side with the march of Science in the Indian Empire, there has advanced an ever-enlarging, ever-expanding stream of civilization, carrying with it light and education, peace and progress and contentment. Such has been England's mission in India, and for the completed record of its work during the reign of Victoria, the millions of India have loved and venerated their Queen-Empress with a devotion that is akin to holy, almost deified reverence. May nothing ever occur to mar their respect and love for England's monarchy, for in these two factors is bound up the peace and contentment of this Indian Empire. "Righteousness exalteth a nation." Even so the righteous life of our beloved Queen has been the ideal for India's faith in our Government. This ideal must find a living reflection in our rulers, the representatives of England's Government. There must be justice, there must be honest dealing, there must be no duplicity. May the same God who has wisely and mercifully and lavishly dispensed His bountiful blessings on the dominions and peoples of our beloved Queen-Empress, continue to bless in like manner the great and glorious Empire of England; and may the prayerful song of the Empire's millions ascend for him of whom "the Governor-General in Council announces that His Most Gracious MAJESTY KING EDWARD THE SEVENTH has been proclaimed KING OF GREAT BRITAIN and IRELAND, and EMPEROR OF INDIA."

ANNUAL REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR THE YEAR 1899.

I.

We are glad to note that the Annual Report of the Sanitary Commissioner with the Government of India appears much earlier in the year than usual. It is indeed no small monument to the energy of those responsible for its production that this mass of vital statistics, embracing the whole of the Indian Empire, should be ready for publication within a year of the time to which it refers.

It is, as we have remarked before, a formidable-looking volume, and no doubt the portentous array of figures which go to make up the second half of it will not readily appeal to the general reader. We are certain, however, that not one of the fifty-three tables of vital statistics could be spared; they have been evolved from years of well-directed labour; they are wonderful compilations and cannot be surpassed for comprehensiveness or lucidity.

There is hardly a fact regarding the health of any corps or station, or the prevalence of any particular disease, that cannot be found in a minute by an intelligent use of these tables. As to the value of this report, there can be no two opinions, and it is safe to say that no medical officer can do his duty to the State, or justice to himself, who does not study and constantly refer to its pages. To such it is full of interest and information, and we would not wish to see it curtailed in any way.

The comments and criticisms of the Sanitary Commissioner are valuable, and often in sympathy with the difficulties encountered by medical officers bound down by many restrictions and an unsatisfactory nomenclature. The references to current European literature are well chosen and are no doubt useful to many who would not otherwise have the opportunity of keeping up with the latest developments in special subjects.

The volume may be considered in four parts, dealing respectively with the health statistics of European troops, native troops, the jail population of India, and the general population. Although the last cannot compare with the others in accuracy, still much is to be gathered from it, and it is no doubt convenient to have all the vital and health statistics brought together within the compass of a single volume.

It has long been the custom to seek

METEOROLOGICAL CONDITIONS.

There are many at the present day who deny the climatic origin of diseases, and seek to explain every pathological condition on the supposition of some specific micro-organism. Whether this is carrying the bacteriological craze too far is still open to question; but there can be no doubt that the experience of years has shown that the health of the year and the prevalence of many diseases is profoundly affected by the prevailing meteorological conditions. Whether this effect of the atmospheric phenomena is direct or indirect, whether it acts directly upon the human organism or indirectly through the medium of minute forms of life by favouring or retarding

their development, it is as yet impossible to say. All that can be said with certainty is that certain diseases are profoundly affected by meteorological or climatic conditions.

The year 1899 is no exception to this rule. The most marked meteorological feature of the year was a deficient rainfall, for "the rainfall of the whole of India for the whole year was in defect by 11.14 inches."

This deficiency was, however, not universal, for in parts of the Empire the total rainfall was in excess, as in Lower Bengal, Upper Burma and the greater part of the North-West Provinces. Speaking generally, the monsoon rainfall was abundant in the east, while in the west and south it was deficient.

METEOROLOGICAL EFFECTS.

Ague, no doubt, is the disease that is most sensitive to climatic vicissitudes, and the result of a dry hot year is very marked in the statistics of European and native troops. In the former, the admission-rate fell from 394 in 1898 to 235 in 1899: in the latter, the fall was from 335 to 260.

Again, amongst European troops we have an increase of ague with an abundant monsoon, and *vice versa*. In Bengal and Orissa the admission-rate increased from 603.5 to 658.1, and in Burma Coast and Bay Islands from 56.3 to 187.4, while there was a reduction from 766.3 to 276.9 in the N.-W. Frontier, Indus Valley and North-Western Rajputana.

Amongst native troops the regiment that suffered most was the 12th Bengal Infantry, which was quartered in Calcutta. "It is stated," the Sanitary Commissioner informs us, "that some of the villages in *that part of the country* (*sic!*) were being deserted on account of malaria."

"*That part of the country*" is certainly a curiously vague way of alluding to the neighbourhood of Alipore, a suburb of Calcutta, where this regiment was stationed.

In all four divisions of the Sanitary Commissioner's Report we have the fact emphasised that the year 1899 was an unusually healthy one, and it is interesting to note that the dreaded scourge of cholera was much less prevalent than usual.

CHOLERA.

Amongst the whole of the European troops in India there was only one case which proved fatal. Commenting upon this, the Sanitary Commissioner says: "This phenomenal freedom from the disease has no parallel in the medical annals of the army in India."

Amongst native troops, on the other hand, there were 124 admissions with 68 deaths, against 44 admissions with 42 deaths in 1898. The figures for prisoners were 101 admissions with 62 deaths, against 23 admissions with 14 deaths in 1898. These figures are taken from the statistical tables at the end of the report. Curiously enough, they do not agree with those given by the Sanitary Commissioner in his remarks in the first-half of the volume.

Amongst the general population, cholera was much less prevalent than usual, though, as in the case of native troops and prisoners, it was more prevalent than in 1898.

In 1898 the number of deaths in the whole of India was 152,703, and in 1899 it was 171,410; the latter figure is said to be "considerably less than that recorded in an average year in Bengal alone.

No explanation is given to account for the great falling off in cholera in 1898 and 1899.

INFLUENZA.

A disease which appears to have taken a considerable hold in the country is influenza. In 1894 the Sanitary Commissioner was sanguine enough to express the opinion that there is "some ground for hope that the disease is gradually wearing itself out." This hope has, however, not been realised; and the year 1899 is marked by an increase both in European and native troops, while there is a falling-off amongst prisoners.

The year 1890 was the first year that influenza became epidemic. In that year there were 2,263 admissions amongst European troops, 8,217 amongst native troops, and 7,643 amongst prisoners.

Nothing like this has occurred since, but during the last three years the figures have steadily increased: in 1897 they were 272, 695 and 987 for European troops, native troops, and prisoners respectively; in 1899 the figures are 674, 1,586 and 1,622.

The disease has also spread further and apparently taken a more extensive hold upon the country. A weak point in the report is that no mention is made as to the prevalence of the disease amongst the general population. That they are not exempt from it we may assume from the fact that native troops and prisoners suffer; but we are in complete darkness as to the extent of its ravages.

There can be no doubt that the accurate diagnosis of influenza is a matter of much difficulty, and we should very much like to have some information as to the symptoms that are most reliable in this respect. We gather from the report that the difficulty has been freely admitted by several medical officers, but we look in vain for any assistance, with the exception of a remark about bacteriological methods, which unfortunately are out of the reach of most military hospitals. At Barrackpore the likeness of some of the cases to dengue was noted; we should like to have some information as to the differential diagnosis. Again, in 1899, the Jhansi report states that the diagnosis between influenza and simple continued fever is variable; and the Medical Officer at Rangoon states that some of the cases returned as ague were probably influenza.

The death-rate amongst troops is, as might be expected, very low; for influenza is not a fatal disease amongst people in the prime of life, unless neglected. It is more to the point to notice that it is nearly twice as high amongst prisoners as amongst native troops, and again it might be expected to be very much higher amongst the aged and broken-down in the general population.

PLAGUE.

Amongst European troops there were seven cases of plague with two deaths, against nine cases with two deaths the previous year. The stations which returned cases were Poona, Kirkee, Ahmednagar and Deolali.

In the native army there were 76 cases with 45 deaths, against 94 cases with 58 deaths in 1898. The regiment that suffered most was the 21st Madras Infantry at Belgaum.

We are at a loss to understand why these cases are not shown in Tables IV and XXIX with all other diseases.

In the jails of India, only five cases occurred with two deaths.

Amongst the general population, as far as the returns sent in go, there were 139,009 deaths in 1899, against 116,285 in 1898.

There was a very large increase of plague in Bengal, from 219 to 3,264; in Madras Presidency, from 557 to 1,568; in Bombay, from 86,191 to 96,596; in Mysore, from 5,335 to 10,810; and in Hyderabad, from 3,868 to 6,378. Of the 3,264 deaths recorded in Bengal, Calcutta was responsible for 2,681.

PERSONAL EXPERIENCES IN APPENDICITIS.

MR. HERBERT W. ALLINGHAM, F.R.C.S., Surgeon to the Household of H. R. H. The Prince of Wales, Surgeon to the great Northern Hospital, and Assistant Surgeon and Lecturer on Operative Surgery to St. George's Hospital, contributes a valuable and interesting paper to an English contemporary, detailing his personal experience on the much-discussed subject of appendicitis. We give the essentials. In such cases, it is pointed out, statistics are of little or no value, because many cases appeared well for the time and were lost sight of: cases of third or fourth attack would be reported in their second or third attacks as cured without operation. In the writer's opinion the great majority, if not the whole, of such cases should be looked upon from a surgical point of view. The seriousness to life of the affection was due to the position of the appendix in the abdominal cavity, where, if an abscess burst, the pus must either make its way into some neighbouring hollow viscus, or infect the general peritoneum, and so give rise to one of the worst forms of sepsis. For practical purposes, there were three sets of causes: (1) Foreign bodies, such as seeds of fruits, hardened faecal matters, and pins or beads, etc. (2) Different forms of ulceration—catarrhal, tubercular, syphilitic, dysenteric, or even typhoid. (3) Malposition of the appendix, causing it to become strangulated on itself, or to favour retention of foreign bodies. The pathology was the pathology of inflammation from any of these three causes. If the inflammation was moderate, the attack was only catarrhal: if severe the condition might proceed to ulceration: if grave, gangrene might supervene. In women, doubt in diagnosis often arose on account of disease of the right ovary, extrauterine gestation, or, in both sexes, some irritation in the course of the ureter. At times it was impossible

to be absolutely certain that the appendix was at fault. In these cases the speaker's plan was, on the appendix being found normal, to systematically examine the ovary and tube on the right side by enlarging the ordinary incision downwards. If in doubt, it was far safer to operate, because operation, if too early, did no harm, and if too late, was generally hopeless. Mr. ALLINGHAM's experience enabled him to make three main divisions of appendicitis:—

I. *Extremely acute appendicitis*.—No history of previous attack: condition—abdomen rigid and tender, greatest tenderness over right iliac fossa: legs drawn up: abdominal aspect: temperature above normal, not necessarily high: pulse out of proportion to temperature: *rapidity of pulse was of the greatest importance*, and was the most reliable symptom: vomiting might be present, but constipation or diarrhoea was of no moment as a symptom. The history was always a sudden seizure. In these cases pus was in all probability free in the abdominal cavity.

Treatment.—Immediate operation before the pus could infect the general peritoneum so as to render the patient septic. Every case operated on by the writer, in which general septic infection had thoroughly got hold of the patient, had died; whereas in those cases in which operation had been immediate, or within a few hours after perforation, recovery had followed without exception.

II. *Recurrent chronic appendicitis*.—History of one or two previous slight attacks: general condition revealed practically no indication of mischief: fever slight, and pulse not out of proportion to the temperature, abdomen soft, with often some tenderness over right iliac fossa and slight rigidity of abdominal muscles there.

Treatment.—If temperature and pulse taken every four hours show after 24 hours that there is a tendency towards falling, leave patient surgically alone, and wait a week or a fortnight and then remove appendix.

III. *Acute attack supervening upon a chronic appendicitis*.—History of two or three previous attacks: present attack much severer, with symptoms resembling those of the first class.

Treatment.—Immediate operation. There was everything to gain in operating early, the adhesions being recent and easily separated: after each attack more adhesions formed, and the old ones became firmer, rendering the operation more difficult and dangerous.

The appendix might be found in different positions in the abdomen: (a) Free and quite moveable in the abdominal cavity—the commonest. (b) Resting in one of the pouches round and about the cæcum, and liable thus to escape notice. (c) In recurrent appendicitis, hidden or incorporated in and with adhesions between the cæcum and the abdominal wall, and thus very easily overlooked. One important feature alluded to by the writer is that the presence of a mass in the right iliac fossa is not necessary as a proof of appendicitis. The most serious and dangerous cases were those in which no mass whatever was felt.

Operation.—The best incision was the usual oblique one, made on a level with the anterior superior spine of the ilium, and about one and a half to two inches to the inner side of it: skin divided: abdominal muscles separated with the fingers, thus interfering as little as possible with them, and rendering subsequent hernia less liable: abdomen opened: appendix sought for and freed from connections by the fingers, for it could thus be best appreciated what parts were giving way, and there was less likelihood of tearing the gut or neighbouring parts. The best treatment of the appendix was to make a sleeve of peritoneum as advocated by BARKER, to ligature the appendix near its base, to touch the end of the stump with some pure carbolic acid, and then to bring the sleeve of peritoneum over and tie a ligature round the end of the sleeve. If a friable appendix be torn away from the cæcum, invert the stump into the cæcum, and put in a couple of stitches, sewing the peritoneal surfaces over: if not possible, pack abscess cavity with iodoform gauze: fistula in such cases was unavoidable: a spontaneous closure in the course of time could, however, be anticipated. If the appendix were curled up underneath the cæcum, free the adhesions binding the cæcum to the iliac fossa, so that the cæcum could be turned over into the abdominal cavity. If a large abscess had formed, blocked off from the general peritoneal cavity by adhesions, the treatment was that of any other abscess. If the appendix was easily seen and not very adherent, it might be removed then and there: if, however, there was the slightest difficulty in finding it attended with any risk of opening up the general peritoneal cavity, it was far better to leave the diseased appendix alone. In acute cases, where the appendix had burst and pus was free in the general peritoneal cavity, the best procedure was to sponge away the pus and then fill the abdomen up with sterilized water. The water diluted the poison if there were any left, became absorbed and improved the general condition of the patient. The surgical treatment could only be carried out satisfactorily by the common sense of the surgeon: fixed rules were impossible in the greatly varying conditions to which the appendix was liable in disease and in health. The *after-treatment* consisted in treating symptoms. If the patient be thirsty, give him drink: if restless or in pain, small doses of morphia ($\frac{1}{4}$ gr.) repeated if necessary: if distension occurred, means should be taken to overcome it, the use of the rectal tube for two hours at a time every six hours being the most useful, or a turpentine enema repeatedly given: should these fail, and vomiting be not present, castor-oil, followed by repeated doses of sulphate of soda or magnesia, was beneficial, and, with vomiting, repeated small doses of calomel (3 grs.) placed upon the tongue. Lastly, Mr. ALLINGHAM advocated allowing the patient to lie in bed in any position. There was a rule that a patient, after an abdominal section, should be kept on the back: the writer had often found this detrimental, creating much discomfort attended with sleepless nights; whereas liberty to the patient to sleep in any position often ensured a perfectly good night. In those cases where untoward after-effects were happily absent, the wisest course was to avoid any active treatment.

COMMENTS AND NEWS.

REMARKS ON PROPER AND IMPROPER BURIAL, WITH SPECIAL REFERENCE TO CREMATION.

In a communication to the *British Medical Journal*, Sir FRANCIS SEYMOUR HADEN, F.R.C.S., England, the well-known advocate for "earth" burial, summarises his views expressed in numerous controversies during over 20 years with eminent supporters of cremation as the method of disposal of the dead. We extract the essentials. The case for earth burial might be shortly put thus: (1) The natural destination of all organised bodies that have lived on the earth, and that die on the earth's surface, is the earth. (2) The evils supposed to be inseparable from the principle of interment are independent of that principle and of our own creation. (3) The source of these evils is to be found, not in the burial of the dead, but in the unreasoning sentiment which prompts us to keep them unburied as long as possible, and then to bury them in such a way that the earth (or rather the air) can have no access to them. (4) The principle of burial supposes the resolution of the body by the agency of the earth to which we commit it, and that the earth is competent to effect that resolution and to effect it innocuously. (5) To seek to prevent the beneficent agency of the earth by enclosing the dead in imperishable coffins, brick graves and vaults is in the highest degree irrational, since it engages us in a vain resistance to an inevitable dispensation, and has led us to accumulate in our midst a vast store of human remains in every stage and condition of decay. (6) Unwarned and undeterred by this magnitude of evils, we were still extending and perpetuating them. (7) Were the dead only properly buried, not one of those evils would have any existence, not a single dead body would remain to encumber the soil, and a quantity of land of incalculable value, now hopelessly alienated, would be liberated for purposes of hygiene or of utility. (8) The remedy for such evils was, therefore, not in cremation, or in any of the alternatives that have been proposed for burial, but in a sensible recognition of, and a timely submission to, a well-defined law of nature, and since some of these alternatives were dangerous in legislative action to enforce the provisions of that law. (9) The claim that earth had upon its dead, no less than that which the dead had upon the earth, was in short, a proposition too obvious to merit discussion. To understand it, we need only consider the properties with which the soil at our feet and everywhere had been endowed: that it was the most potent disinfectant known, and the readiest of application, and that by a combination of forces inherent in it, which might well appear contradictory but for the wonderful purposes they are destined to effect, it is resolute and reformatory as well: that that which under the influence of the air was putrefaction, in the earth is resolution: that which was offensive becomes inoffensive: that which was mere decay a process of revivification. To question the competency of the earth thus endowed, to effect the resolution and conversion of its dead, or to fail to perceive and profit by that competency, would pass comprehension if habit had not taught us to shut our eyes to it, and if the advocates of cremation had not stepped in to tell us that we might improve on it. The conclusions arrived at by the writer at the end of the prolonged discussion were: (1) That the Cremation Society had created a very general impression that there was only one kind of burial and only one remedy for it—cremation—a statement which was quite misleading. (2) That this belief had been greatly asserted by the systematic suppression on the part of an influential portion of the

press of all effectual answers to the cremationists' statements, and that in this way the country had become flooded with these unopposed fallacious statements. (3) That the Government was equally to blame for allowing the abuses referred to to go on, and was therefore, to that extent, responsible for the cremationist agitation. (4) That burial, as at present carried out in coffins which prevented the resolution of the body, was equally a reproach to the intelligence of the country, and to the Government which permitted and prescribed such a practice. (5) That to make the practice of burial perfectly harmless, and to do away with all excuse for cremation, nothing more was necessary than to take the whole management out of the hands of the undertaker and speculator, and to make it a matter of State or Municipal regulation. (6) That while the earth, properly used, was capable of disposing of any number of dead bodies insensibly and with advantage, both to its own substance and to the air above it, the practice of cremation, on a scale large enough to have even the slightest influence on burial, either as a rite or a custom, supposed the necessity not of one, but of many furnaces, the use of which in or near towns no municipal authority would for a moment permit, and which, even in the open country, would cause such a consumption and carbonisation of pure air as to render (changes of wind considered) a large area in the neighbourhood uninhabitable. (7) That the cremationist statement that burial, however conducted, was "a propagator of infection and a cause of increase in the zymotic death-rate," was not only untrue, but abundantly disproved by expert evidence from all parts of the country. (8) That there was no definite statistical evidence to show (a) that the general death-rate, or (b) the zymotic death-rate, or (c) the death-rate of any group of diseases, or (d) the death-rate from any single disease, zymotic or otherwise, had ever been affected by burial, even under the present objectionable conditions. (9) That statements of the number of exhumations practised, and of murders discovered by them, is incorrect. (10) That the statement in *modern cremation* which allowed the reader to infer that, "though exceedingly rare in this country," it could not be altogether denied that premature burial was possible, while "with cremation no such catastrophe could ever occur," was fairly disposed of by the negative reply to Mr. HADEN's questions on the subject of trance by such eminent men as GEORGE BURROWS, M.D., President of the Royal College of Physicians, WILLIAM FERGUSSON, WILLIAM GULF, M.D., WILLIAM JUNNER, JAMES PAGET, and THOMAS WATSON, M.D.

MODERN ANATOMY.

In a paper read before the Philadelphia County Medical Society, Dr. EDMUND HOLMES animadverted against the present system of tuition in anatomy at medical schools. We extract the important observations from a report in the *Journal of the American Medical Association*. There were three fallacies in the present method of teaching: (1) A large public clinic for so-called practical clinical instruction. (2) A main reliance upon didactic methods in all branches. (3) An old style dissection room. It was pointed out that the time for the didactic lecture was passed, owing to the greater equality in intelligence between the teacher and the taught. Although anatomy was the basis of the whole medical fabric, it was also the most difficult, and received the least practical attention. The modern dissecting room should be clean, accessible, under strict supervision, open during certain hours only for earnest individual work: the daily task outlined upon the blackboard presupposing two hours' study at home the evening before in preparation for the following day's dissection, not with a single man, but

with a large corps of competent assistants, all in attendance throughout the assigned hours of dissection, material in abundance, the bodies well preserved and thoroughly cleaned. The student must know something of anatomy before he commences to dissect, and the dissection of the whole body during each of the first and second years, and a re-dissection for applied anatomy during the third year, should be the minimum of requirement. Modern anatomic education required the highest intellectual training as a preliminary in which histology, embryology and comparative anatomy form part. With the modern methods of precision in diagnosis and practice, the knowledge of the facts of anatomy was never so important, yet in medical schools human anatomy was often pushed aside by the less important glogies and isms. The teaching of a medical school should be mainly upon human anatomy, and should be mostly upon cadavers, with didactic lectures only as an adjunct, the stock drilling and teaching being by younger men, who should have decent remuneration, while the professor, freed from the exhaustion of elementary work, should have time to devote himself to original research and to the instruction in the higher elements of his art. The scope of this branch had enlarged so tremendously that the tendency was to lead its teachers not, as formerly, into practice or surgery, but into the fields of scientific research. The medical profession was lamentably weak in this subject—far weaker than they would dare to confess to the general public, or perhaps even to each other—and this not because they had forgotten, but because they never knew it: they were never properly taught it: they were never given sufficient facilities for study or review, were never sufficiently impressed with its importance, and because they were taught by hearing, and not by touch, by faith, and not by sight. The instruction should be practical, and communicated not only through the ear, but also by the eye and by the hand. It should not be forgotten that the majority of students must necessarily be practitioners, not scientists, and in schools, therefore, devoted to the evolution of the everyday physician, the facts taught should be broad, major, practical, rather than minute, scientific or theoretic.

FREQUENCY OF CRIMINAL ABORTION AMONG THE MARRIED.

THE *New York Medical Journal* discusses in a leader the disquieting frequency of criminal abortion, especially as occurring among respectable married women, who were often in other respects of high moral character, great natural refinement and culture. We give the essentials. The existence of this practice was apparent from the large and lucrative trade in abortifacients. The primary error lay in a misconception of the term "love." Two views were admitted: (1) That love with the vast majority was a means of purely sensual gratification, which was legitimised by "marriage." (2) That the performance of the sexual act was mainly and primarily for the procreation of the race. Any fraud concealing the fact of a known incapacity for motherhood—as after oöphorectomy—was of course a just and reasonable ground for the annulment of the marriage bond; but this view alone reduced the glorified companionship of matrimony to the principles of a stud farm. Neither of the above views was consistent with the true ideal of love. The true idea of love was an earnest yearning for the most complete and intimate union, harmony of vibration and mutual absorption attainable between two beings, each of whom is both the lover and the beloved. As between man and his religion the mode of union would be purely spiritual: in a solely material existence it would be purely

sensual: in man it partook of both in direct proportion to the balance between the physical and spiritual natures of the individual. Were women as (physically) passionate as men? The reply was "yes" and "no." The normal woman was ready to yield herself wholly to the man she loved intuitively, realising the inner significance of the act. But when she came to recognize the sensual character of man's interest in it, even when he is genuinely attached to her, that which should be the cup of sweetness often become bitter as wormwood. The act of sexual union, undertaken solely for the production of a physical sensation, was as impure and lustful, whether legal or not, as an act of communion would be unholy in the Christian if done solely from a desire to appease hunger with the material bread, or to gratify the palate with the sensuous flavour of the wine, no matter though the act were done with all due observance of the rites and ceremonies prescribed by the religious body to which the individual happened to belong. Such an exultation of emotional desire in the sexual act was often wanting, and the after-effect was undoubtedly a blunting of the moral sensibilities as regards the eventualities of such congress, and the transmission of an excessive sensuality to the progeny. From the social side the difficulties placed in the way of young people mating, in whom the real higher emotion existed, led not infrequently to "illicit" intercourse and an illicit union (which was by no means necessarily lustful in itself, though it probably arose from lust rather than love in the large majority of cases), and possibly an unexpected and unwelcome pregnancy entailing social outlawry unless obviated. The result was abortion, regarded by the distracted sufferers as the lesser of two evils. When the congress was the result of lust, even in the married, pregnancy was invariably unwelcome. A more thorough understanding and appreciative practice of actual purity, which was a matter of motive, not of act, among the married, together with the proper and progressive enlightenment of children on the subject, would change the entire public estimate of marriage, and by removing social and other impediments to the lawful expression of the imperious emotion of love, would at least relegate criminal abortion to the class of the essentially depraved.

TOBACCO AS A LUXURY.

A STRONG and standard medical authority, the *Lancet*, has recently come out emphatically in support of tobacco as a luxury, which has been proved in the Transvaal to have great power in enabling men to bear hunger and fatigue. This will horrify those enthusiasts who persuade themselves and try to persuade others that tobacco is of the Evil One as much as intoxicating drink, notwithstanding the obvious fact that tobacco at its worst does less harm to body and soul than drink at its best. But where the *Lancet's* position will stagger people who read the papers is in its opposition to the copiously published opinions of doctors and laymen that smoking is useless, deceptive, and hurtful, so much so that certain of those funny States across the Atlantic have legislated against the practice. We should have more confidence in the opinion of the *Lancet* were it not that only one generation ago equally high medical authorities were unanimous in commending alcoholic stimulants in a way which scarcely one medical man of repute would do now, and that they were always ready to prove what they said.

DEPUTY SURGEON-GENERAL GEORGE**MACKAY, M.D., J.P.**

THE *Edinburgh Medical Journal* says:—By the death of Deputy Surgeon-General GEORGE MACKAY on the 20th of November, Edinburgh has to deplore the loss of one who played no minor part in the branch of medicine chosen as his role in life, and who, after retirement, continued to employ his time for the good of his fellow-men.

Fittingly a child of the army, GEORGE MACKAY was a son of Major MACKAY, of H. M. 70th Regiment, then (in 1820) stationed at Aberdeen, and a grandson of Colonel MACKAY, of Bighouse. While still of tender years, his father's regiment was ordered to Canada. Hence he received his early education in that colony, but he was later sent to the Madras College at St. Andrews. Resolving to enter the medical profession, he entered Edinburgh University, and graduated in 1841 as M.D.

Hereditary instincts it may have been which caused him to aspire to a military career; and soon after graduating, he applied for and obtained a commission as surgeon in the Honourable East India Company's service. During the course of his duties in this capacity he saw active warfare in the campaigns against the Mahrattas in 1844, and in Burmah in 1852. The medal and clasp for Pegu were conferred on him, and he was specially thanked for his services during the campaign.

After this last war service he settled at Coimbatore as a civil surgeon, later on proceeding to Ootacamund. Raised to the rank of Surgeon-Major in 1864, those in authority marked their appreciation of his abilities by appointing him to the post of Examiner of Medical Accounts in the Military Finance Department—an appreciation evinced further by his subsequent appointment to the Secretaryship of the Madras Medical Fund and Military Fund.

Privileged to read a record of service personally written by the late Deputy Surgeon-General, the writer is able to testify to the very varied experiences which fell to his lot, and the constant devotion to duty characterising his entire career. Among a number of points of interest, the fact of his having in 1845 had the courage to attack the then customary and universal method of treating cases of heat apoplexy by copious bleedings and detergents—notwithstanding the almost invariable fatal result—by advocating and successfully applying a method of treatment of cold to the head, moderate stimulation, and a following purge very similar to that adopted generally at the present time, bespeaks a man of mettle.

In India he was one of those who first advocated more thorough training of native medical subordinates—a movement leading in time to the institution of the Madras Medical College. His philanthropic turn of mind induced him to fill many honorary posts in societies formed for the public weal in India in addition to his official work. Having served for practically thirty-three years, thirty of which on actual duty, he retired in 1875, first settling in Inverness, but latterly residing in Edinburgh. His leisure time he occupied in aiding the Soldiers' and Sailors' Home, as well as many other philanthropic enterprises.

CERTAIN OBSERVATIONS ON THUNDERSTORMS.

THE *Indian Meteorological Memoirs* (Part ix. vol. vi.) contains an interesting discussion of the thunderstorm observations recorded in 1897 at ten selected stations of this country, by Mr. W. L. DALLAS, as will be observed from the following note reproduced from *Nature* (August 23, 1900):—

"The results for the year have been divided into five-day periods. The storm-frequency varies considerably in different parts, but, generally speaking, the number of storms is unimportant during February and the early part of March; but after the middle of March the thunderstorm season commences, and continues until the middle of October, the maxima occurring towards the end of May and September. After October 23 no storms are reported. Storms are much more frequent in the afternoon than in the morning, and when a storm occurs in the forenoon it is followed, almost without exception, by another in the afternoon. There is a belief that the damage done by lightning in the tropics is slight compared with that done in temperate zones, and the fact that at ten observatories in the year in question only four instances of damage being recorded gives support to this belief."

As observed before, electrical variations and disturbances form an important part among meteorological phenomena, and meteorology has a great bearing on morbi-geneesis. It is therefore necessary for our profession that observations like the above should be made and recorded on an extended basis.

SALTPETRE IN INDIA.

MR. J. E. O'CONNOR, Director-General of Statistics, in a report on mineral production in India, states that saltpetre, which is largely produced for export, was in former years of much greater importance, than now, the decline in its employment for gunpowder and the preservation of food having led to a restriction of production. The average production, of which the bulk is made in Behar, amounts to only about 250,000 cwt.; of this a considerable proportion is exported after refining in Calcutta.

SHORT ITEMS AND PERSONALITIES.

The Church Mission in the Punjab is being reinforced by Dr. Sidney Gaster, M.A.C.S., B.S.C.P., who is expected at Dera Ghazi Khan in January, and who has been working in London in connection with the Islington Medical Mission; and by Miss Minnie Gomery, M.D., at Islamabad. Dr. A. H. Browne probably returns from famine work in the Bhili country to Amritsar in January. In Amritsar, Major H. A. Haines, B.A.M.C., is a valued helper in the work.

The habit of drinking petroleum is spreading to an alarming extent in many districts of France. It has apparently been prevalent for some considerable time without being recognised, and is quite as persistent a habit as alcoholism. Though petroleum does not make the drinker brutal, but morose, there is no doubt that, so far as the victim of the vice himself is concerned, it is even more deadly than ordinary drunkenness.

We are requested to state that the Central Committee of the Dufferin Fund has at the moment several applicants upon its list of candidates for employment who are available for early employment. Native States and Local Committees who are in need of the services of Lady Doctors, Assistant Surgeons, or Hospital Assistants, are invited to apply to Colonel E. H. Fenn, Honorary Secretary, Viceroy's Camp.

There were 2,463 reported plague deaths in India for the week ending the 5th January, as against 1,386 last year during the same period. Of these, 1,500 occurred in Patna, Saran, Monghyr and Gaya districts in Bengal. The Bombay Presidency reported 261 deaths, Mysore 414, and Bombay City 171. There were 25 deaths in the Madras Presidency, 14 in Hyderabad State, and 11 in the Punjab.

Stuttering is considered contagious in Germany. There are over 80,000 stuttering children in the schools of that country, and the number is steadily increasing.

It is said by his friends in Calcutta that Lieut.-Colonel R. D. Murray, I.M.S., the "Professor" of Surgery at the Medical College Hospital, goes home "to qualify" for his post in March. He will, it is reported, write his "thesis" for his M.D., and "take" the Fellowship of the Royal College of Surgeons of Edinburgh "by election." Why not by "examination"?

Miss A. E. Kemp, of the Medical School, Ludhiana, writes: "Dr. Edith Brown is proceeding to England per S.S. *Ellis* on January 27th, for a much needed rest. Dr. Eleanor Dodson, whose death from cholera was erroneously reported in an Indian paper some time ago, has recovered, and hopes to sail for home in March."

We understand that the Government of India will shortly partially reopen the granting of leave to officers of the Indian Medical Service, but it is impossible to reopen the granting of usual leave just now in consequence of a large number of officers now employed in China as well as on famine and plague operations in India.

The hospital ship *Gwalior*, according to present arrangements, will sail from Calcutta for China on the 6th proximo. Several improvements have been carried out on board, and special accommodation for European patients has been provided.

A scientist, after years of experimenting, has succeeded in colouring the plumage of birds by the administration of food mixed with aniline dyes. In this way he has, it is stated, produced red and blue pigeons, and has imparted to canaries all the tints of the rainbow.

The native Hospital Assistant in Bangalore, who recently created a certain amount of sensation by professing the possession of a perfect cure for plague, has been examined by the Medical Board under the presidency of the Senior Surgeon to the Mysore Government, and pronounced insane.

The Government of India have sanctioned the issue of two field stretchers to each hill depot and standing camp in the hills, in order that men may be trained as stretcher-bearers during the summer months.

Plague is raging in all parts of the town of Monghyr, and in consequence about half of the residents have already left it. In Basudeopore and Madhupur many houses where plague cases occurred have been burnt down.

The Government of India is making all arrangements for the Field Hospital with the Ogaden-Somali Expedition, and some Volunteer Medical Officers as well as hospital assistants will be taken if required.

The Pasteur Institute at Kasauli is working well, and since its opening more than 110 patients have undergone the treatment under Major Semple, B.A.M.C.

The Chinese never wear wool—not even in the depth of winter; and, generally speaking, the entire population clothe themselves in cotton all the year round.

Medical Appointments, Transfers, Exchanges are easily and cheaply effected through our special short advertisement page. See terms and apply at once.

The *Indian Medical Record* offers the following prizes:—Rs. 10 to Rs. 16 for a good Original Article; Rs. 5 to Rs. 10 for a good Clinical Report. Competitors must be subscribers to the *Record*.

Members of the Indian Medical Association will kindly note that while the entrance fee to the Association is fixed at Rs. 5, the annual subscription is reduced to Rs. 2.

Current Medical Literature.

MEDICINE.

Epilepsy: Its Etiology and Pathology.

AFTER reviewing briefly the various theories of the causation and pathology of epilepsy, W. HOUSE (*Phil. Med. Jour.*), believing that "like causes produce like effects," compares the symptoms of epilepsy with those of diseases which produce or are accompanied by convulsive seizures, resembling more or less the seizures of epilepsy. These diseases are hysteria, tetany, the eclampsias, alcoholism, cerebral hæmorrhage, and the apoplectiform and epileptiform convulsions of general paresis. The pathology of the three latter conditions is well known, and in certain respects the lesions are of a similar nature. The symptoms of an epileptic seizure, of an epileptiform parietic convulsion, of an alcoholic convulsion, and of cerebral hæmorrhage, present a marked similarity, so much so that sometimes it is difficult to make a differential diagnosis. Symptoms of cerebral pressure are present in these three conditions, and also in epilepsy. In the brain of an alcoholic there is an excessive quantity of cerebrospinal fluid, the ventricles are distended, the brain-substance drips with fluid, and the membranes are dropsical. This is called the "wet brain." In general paresis the ventricles are distended with fluid, there is an increased quantity of fluid in the subdural space, and the whole brain is surrounded with an excessive quantity of turbid cerebrospinal fluid. In both these conditions the excessive fluid seems to the author to be the logical cause of the pressure symptoms recognised in convulsions from these diseases. HOUSE has witnessed the autopsies of five cases of status epilepticus, and in each instance there was found an excessive quantity of cerebrospinal fluid. Arguing from analogy, HOUSE is forced to the conviction that this increase in the quantity of cerebrospinal fluid must bear a causal relation to the convulsions of epilepsy. According to physiologic findings, if the cerebrospinal fluid be suddenly withdrawn, convulsions may ensue; if rapidly increased, coma may be produced. From observation of over two hundred epileptics, and comparing their symptoms with those of sixty alcoholics and those of a large number of parietics from the findings in the above five autopsies, and from an analysis of recent literature, he concludes that: (1) There is no record of pathologic findings which logically explain the symptoms of epilepsy. (2) An increase of cerebrospinal fluid would readily account for the seizures. In many instances it is analogous to the marked increase of fluid in the crania of alcoholics and parietics, and is not dissimilar in clinical effects to the more localized lesions of hæmorrhage or abscess. (3) This fluid, physiologically subject to more or less variation in quantity from day to day, is fully capable of pathologic increase, and from analogy must bear exciting relation to the convulsion. (4) Its increase is probably gradual, and to this we may ascribe the *auræ*. (5) Its absorption probably begins with the third stage of the convulsion.

(relation and coma), and if this fails, repeated convulsions (status epilepticus) ensue. (6) Its superabundance may be due to lymphatic spasm, or to marked disturbance of equilibrium between lymphatic and general circulatory activity, which may be favored by heredity, toxæmia, or any of the recognized predisposing causes. (7) This creed applies to the so-called idiopathic epilepsy, as distinguished from the convulsion of JACKSONIAN epilepsy, although even in such cases this condition will help to explain some otherwise unexplainable symptoms.

Acetonuria.

THE most useful clinical test for acetone in the urine, according to RONSSE (*Annales de gyn. et d'obstét.*), is that of LUGOL, which is performed by adding a few drops of LUGOL's solution to the first 10 c.c. obtained by distilling 400 c.c. of fresh urine, then adding sodium hydroxide solution until the brown color disappears. In the presence of acetone a milky precipitate of iodoform is produced, and may be recognized by its violet coloration with caustic soda and thymol, or by its yellow hexagonal crystals under the microscope. Acetone is found in small quantities in the urine normally, and it occurs pathologically in diabetes, cancer, phosphorus or chronic lead-poisoning, certain digestive troubles, hysteria, in prolonged fevers, the acute exanthemata, in eclampsia, and during pregnancy. It is especially marked during prolonged labor, and many writers claim that it indicates death of the fetus, but in a study of fifty-three cases RONSSE finds that it has no such significance.

Early Symptom of Measles.

SLAWYK, of HEUBNER'S clinic, draws attention to the eruption present in the mouth during the early days of measles, first described by KOPLIK. It consists of shining red spots, in the middle of which there are very minute bluish-white efflorescences. SLAWYK says that KOPLIK'S spots have not received the attention which they deserve, and that they represent an absolutely trustworthy and early indication of the disease. During last winter an epidemic of measles broke out in some of the clinics of the Berlin Charité. These cases, along with those of HEUBNER'S clinic, numbered 52 cases, and in 45 of these KOPLIK'S spots were observed. In two of the remaining cases the patients were too ill to permit of a satisfactory examination of the mouth. The spots appeared on the mucous membrane of the cheek and sometimes of the lips. They are mostly few in number. A bright light is necessary, as they are not visible in a yellow light. They practically never run together. They are distinguished from thrush by their colour and their rounded contour. They may be picked off with the forceps without pain or bleeding, and they are then seen under the microscope to consist of large masses of epithelium undergoing fatty changes. They have not been observed in other acute illnesses. In every case where they were seen the measles rash followed, so that whenever they were present the child was at once transferred to the measles ward. KOPLIK'S spots appear on the first or second day of the disease, and increase in numbers up to the time of the skin eruption; they usually further remain for three or four days, so that they last from three to six days. They produce no discomfort. In some cases of measles followed by a stomatitis they were absent. No prognostic significance can be attached to them, as they were present both in mild and severe cases. Details of eight illustrative cases are given.—*Brit. Med. Jour.*

SURGERY.

Post-marital Amblyopia.

JONATHAN HUTCHINSON, F.R.S. (*Archives of Surgery*), reports three cases of young, robust men who developed sudden amblyopia amounting to almost total blindness within from ten days to three weeks after excessive sexual intercourse. "These three cases, so remarkably alike, seem to show that this form of amblyopia, like that due to smoking, is usually recovered from, and is not liable to relapse. It differs from tobacco amblyopia, in that it is much more rapid in its development, and in that it passes to a much higher degree. Tobacco amblyopia usually requires months to develop, and rarely approaches blindness. Recovery from it is also much slower. In both forms, however, there are possibly a few cases in which the disease advances to complete and permanent blindness. Possibly this happens when the cause is never suspected and never removed. The cases under notice are not, as a rule, attended by any failure of sexual power, nor are the tobacco cases attended by any distaste for smoking or consciousness of the patient that it is injuring him." This affection Mr. HUTCHINSON terms "post-marital amblyopia." Possibly the failure of sight sometimes observed after parturition is similar. Rapidly produced and all but complete blindness without visible changes, and rapid and complete recovery, are features of all. Sexual excess under any circumstances may induce failure of sight and derange the nutrition of the eyeball; but the post-marital form of amblyopia is quite distinct, and never occurs except in those newly placed under conditions tempting to excessive indulgence.

Radical Treatment for Curvature of the Penis.

DR. EUGENE FULLER says:—The patient, a young man, at twelve years of age had contracted gonorrhœa from his nurse. Tight stricture followed, necessitating internal urethrotomy. Much inflammation ensued, and an indurated area caused the urethra to stand out like a bow on erection. The perineum was laid open from just above the rectum on to the uplifted scrotum. The urethra was then cut across very obliquely in the bulbous region. The penile end, in order to facilitate its retraction, was dissected free from the surrounding tissues for three-quarters of an inch, after which the penis was pulled up and bent back over the pubes, thus inducing a maximum separation of the cut urethral ends. The penis remaining in that position, the penile end of the urethral roof was stitched with fine catgut to its surrounding tissues, while a longitudinal half-inch cut was made along its floor. A perineal vesical drainage tube was inserted, and the author's usual urethral tube adjusted, the perineal incision being sutured. The penis was kept bent back upon the pubes by plaster. The wound healed well and the operation was a distinct success. Two years afterwards the patient had a good free stream on urination and a penis nearly straight on erection, enabling the sexual act to be accomplished.—*New York Med. Rec.*

Chronic Tuberculous Peritonitis in Childhood.

M. EUGENE TERRIEN (*Presse Médicale*) says that these cases may be divided into three clinical stages: (1) The stage of irritative exudation, that is, of free ascites; (2) the period of membranous formation, corresponding to the encystment of the ascitic fluid; (3) the stage of agglutination of the viscera, corresponding to the fibrocaseous condition. The last form is only exceptionally seen. The author speaks of the remarkable enhancement of recovery by opening the abdomen in the ascitic stage of the disease, but decries laparotomy

in the last stage of the disease. If a fluid is shown to be present, simple puncture is advised, followed by lavage with boiled water, or an injection of camphor naphthol, as recommended by RENDU. If the puncture reveals a beginning encystment, laparotomy must again be performed at once. Sometimes hygienic measures and drugs will suffice to bring about a cure in the first stage of the disease.

Recent Progress in Treatment of Scoliosis.

DR. A. HOFFA (*Centralbl. f. Chirurgie*) describes his success in mobilising the rigid scoliotic spinal column with suitable apparatus, the general and special gymnastic exercises by which he stimulates and restores strength to the muscles of the back, until the patient can voluntarily assume the normal position, and the apparatus which he uses to hold the spine in the normal or over-corrected position. This apparatus consists of an iron pad covered with leather, which is applied to the kyphos and held by a leather strap over the shoulder, and a stout iron rod which screws up and down in a threefold slide at the base of the spine, modifying its position in three different directions. The slide is fastened immovably in a long corset which embraces the pelvis. The firm support afforded by this is the chief feature of the apparatus. The article is profusely illustrated.

Inflammation-producing Agents in the Treatment of Wounds.

G. MEYER takes the stand that absolute asepsis is impossible, and that, no matter how nearly perfect the operative technique, there will still inevitably be some infection of the wound. Inflammation is now universally regarded as a conservative process, and its production in a mild degree means an increased power of resistance of the organism through the more active formation of bacterioid toxins. Arguing along these lines, he advocates the use of some mildly irritant application to the neighbourhood of the wound; tincture of iodine answers every purpose, and gives the required stimulus without in any way jeopardizing asepsis.—*Centralblatt für Chirurgie*.

Coxa Vara.

DR. O. B. KENTLEY (*The Lancet*) defines coxa vara as a deformity of the upper epiphyseal region of the femur, in which the caput femoris sinks to a lower level than normal, in extreme cases almost touching the trochanter minor. He believes that this affection is closely associated with, if not always due to, rickets. He states that he has obtained better results from removal of wedge than from linear osteotomy. Author claims priority in description and treatment of coxa vara by virtue of an article published in September 1898, showing relation between rickets and coxa vara.

Danger of Lumbar Puncture.

WE are too apt to overlook the fact that considerable danger is often connected with procedures that are simple and apparently harmless. GUMPERT (*Deutsche medizinische Wochenschrift*) adds two cases of his own to the fifteen of sudden death after lumbar puncture that he finds on record. Most of these deaths occurred in cases of cerebral tumor.

OBSTETRICS AND GYNÆCOLOGY.

Management of Pregnancy occurring in Connection with Myo-Fibromata of the Uterus.

ALEXANDER J. C. SKENE, M. D., LL. D., (*Transactions of the Brooklyn Pathological Society*) says: "In the submucous variety of myo-fibromata pregnancy is exceedingly rare, less so in the interstitial, and most common when the tumor is of the subperitoneal variety."

The size and location of these tumours are also the chief factors in causing the complications which demand special treatment. The presence of small tumours of the sub-peritoneal variety does not, as a rule, seriously complicate pregnancy or labour. It is safe to allow the gestation to go on in such cases. In the early months, conditions may arise which require attention. The neoplasm sometimes causes displacement of the uterus and prevents it rising out of the pelvis as it increases in size. In this way the uterus becomes incarcerated in the pelvis, and if not promptly relieved, the symptoms become urgent. If the uterus is raised and kept in position, the gestation may go on to time. Labour is not interfered with when the tumour is separated from the wall of the uterus (by pedimentation) sufficiently to permit equal muscular contraction. When the tumour is closely connected with the muscular wall of the uterus, expulsive contractions are inefficient and aid to delivery is required.

Large tumours, especially when connected wholly or in part with the middle layer of the muscular coat of the uterine wall, are more dangerous to pregnant women. Such cases never go to the full times of gestation. They either miscarry or die from secondary affections. Miscarriage under such circumstances is very dangerous. Hemorrhage, both during and after the delivery, is liable to be alarmingly profuse, as the contraction of the uterus is imperfect. It may be necessary to pack the uterus to prevent the patient bleeding to death. Sepsis is very liable to develop from an incomplete emptying of the uterine cavity.

Myo-fibromata of the uterus in relation to child-bearing may be classified as follows:—

First, submucous tumours, large or small, cause sterility as a rule.

Second, small subperitoneal myo-fibromata do not always cause sterility, nor complicate child-bearing to a very dangerous degree.

Third, interstitial tumours, and large subperitoneal tumours closely connected with the muscular tissue of the uterus, do not cause sterility in all cases; but they are most dangerous complications of gestation, because they predispose to miscarriage and render delivery always difficult, often impossible, and always exceedingly dangerous.

With regard to treatment, the first class may be disregarded in this discussion.

The second class requires attention in the early months of gestation, in order to keep the uterus in position and aid in its escape from the pelvis up to the abdominal cavity.

The third class demands hysterectomy as the surest means of saving them. The danger attending miscarriages is so great that few survive the peril, and those few are left with their tumours, which may eventually require hysterectomy.

The time to operate is still a question for consideration. In general terms it may be stated that when gestation has been recognised in cases of the third class given above, the operation should be done. Some who would refrain from sacrificing a living fetus prefer to wait until the first indications of miscarriage appear.

Placenta Prævia.

THE *British Medical Journal* says:—AMADEI AND FERRI reported to the Italian Gynecological Congress a series of 97 cases of placenta prævia in 5,136 cases at the Milan Maternity Hospital, a proportion of 1.89 per cent. Eleven were in primiparæ and 86 in multiparæ, and in only 24 cases did the mother reach the full term, all but 1 of these 24 being marginal. In five cases the mother died:

(1) Severe anæmia due to hæmorrhage from the placental site and from a laceration of the cervix; (2) embolism on the second day; (3) embolism during intra-uterine irrigation after delivery; (4) severe anæmia during podalic extraction; (5) acute pleuro-pneumonia on seventeenth day, after dilatation of cervix and use of forceps. The treatment was varied; in two cases it was medical only. Plugging was used in ten cases, loss of one mother and one child; rupture of amnion in 16 cases of longitudinal position of the foetus, no mother and five children lost; in two cases of rupture of the sac after external version one child was lost. In many cases the rupture of the amnion failed to stop the hæmorrhage. Podalic extraction was practised in cases of marginal placenta prævia, where the cervix was more or less dilated, enough to permit the bringing down of the limb. In a case of central placenta prævia, TARNIER'S method was used. (In this hospital continuous traction by means of a weight is often adopted to secure slow extraction with great advantage to the mother.) Turning was done 42 times: 23 by the classical method and 19 by BRAXTON HICK'S method, with eight and seven foetal deaths respectively. Forceps were used in seven marginal cases; in one case the mother died (pleuro-pneumonia). There were three craniotomies in cases of dead foetuses with excellent results as regards the mother.

Operative Treatment of Procidentia Uteri in Elderly Women.

A. LAPHORN SMITH says that in the majority of these cases we find a lacerated cervix, and that this, together with a lacerated perineum, forms the initial lesions which brings about the prolapse. The laceration prevents involution of the uterus, and the latter organ, instead of becoming small and light, remains large and heavy. Owing to the too general practice of keeping women lying on their backs after confinement, the subinvolved uterus becomes a retroverted one by gravity, and when the woman gets up the bowels fall in front of the womb, and the round ligaments are unable to pull the fundus forward again, so that the uterus is forced on to a lower plane in the pelvis. There being no perineal support to oppose both gravity and intra-abdominal pressure, the cervix appears at the vulva, bringing the bladder and rectum with it, causing a chronic cystitis and a dragging pain in the back. In regard to operative measures, we may follow one of two plans, according to the degree of the prolapse and the size of the uterus. If the latter is small and not far enough out of the body to become ulcerated, the safest operation is to make a small incision in the abdomen, and catching the fundus with the bullet forceps, draw it up to the incision and scarify the whole anterior surface of the fundus, and then to sew it to the abdominal wall with buried, chromicised catgut, after which the vaginal outlet is narrowed by a large anterior and posterior colporrhaphy. If, however, the uterus is very long, sometimes the sound measures seven or eight inches deep, and especially if it is badly ulcerated, it is better to amputate all but the upper two inches of it, and then to narrow the outlet.—*Canadian Practitioner and Review*.

PHYSIOLOGY, PATHOLOGY, AND BACTERIOLOGY.

Two Cases of Extraordinary Movement of the Tongue.

DR. F. PLÜDER (*Arch. f. Laryng. u. Rhin.*) describes the two cases coming under his observation of a condition which has been described before, but which is always of interest. One of these patients came to him with a description of a structure which the patient could feel with the end of his tongue. The description which the patient gave was so distinctly that picture which is ordinarily seen by the physician in examining the posterior nares, viz., a description of the locality of the inferior middle turbinate location of the eustachian tube and of ROSENMULLER'S groove, that there was no doubt but that the patient was in the habit of introducing the tip of his tongue behind the uvula and into the nose. This was proven by direct observation, for the end of the tongue could be seen by looking with a speculum and light through the nose. This patient, since his twelfth year of life, had been in the habit of introducing his tongue into the nasal pharynx, and stated that he was in the habit of doing so for the purpose of making manipulations which cleansed the parts.

The second patient was 24 years of age, a merchant, who was intensely neurosthenic, with various nervous manifestations. It was possible in this patient, while the mouth was open, to introduce the tip of tongue into the nasal pharynx.

These cases must be regarded as physiological cases, in no way the result of disease. Such an unrestricted movement of the tongue depends either upon the patient having more or less absolute control over the muscular movement of the tongue upon the floor of the mouth, allowing more than the ordinary amount of movement, or upon the presence of a very long frænum.

Cortical Localization of Sight and Hearing.

CLARENCE A. GOOD (*Amer. Jour. of Med. Sc.*) reports the case of a woman fifty-five years old. About seventeen years previous to her admission to the asylum she had fits at night. These lasted for about two years. When admitted to the hospital she was practically blind. The pupils were equal, reacting to light. She was deaf. The sense of smell was keen. The speech was drawing and the gait lame. She was slightly paretic in all limbs. Cutaneous sensibility was normal so far as could be determined. Mental action was slow and incoherent, memory nil. From April 1892, to her death in November 1893, she suffered from convulsions. The brain was carefully examined, and the writer draws the following conclusions: (1) Destruction of the cortical visual areas will lead to a degeneration of the cells in the geniculate ganglia and the corpora quadrigemina, and to a degeneration of the nerve fibres of the optic tracts and nerves. (2) The macula lutea of one eye is in connection with the opposite angular gyrus.

Granular Degeneration of the Red Blood Corpuscles and its Significance in Clinical Pathology.

MUCH attention has been given to the shape, size, and colour of the red blood corpuscles—generally called erythrocytes when spoken of under one name—and much valuable information as to anæmia can be obtained from them; but few observations with a practical clinical bearing have, so far, been made upon the contents of the erythrocytes other than the hæmoglobin. GRAY'S (*Amer. Jour. of Med. Sc.*) has entered this field, and points out that the

erythrocytes frequently show basophile granules. He thinks that they include a degenerative change in the red cells, due to a degeneration in the blood. They are seen only in cases which lead to degeneration of the blood, and vary directly therewith, increasing or diminishing as it increases or diminishes. Hence they may form an index of the patient's progress. They are probably due to the action of deleterious substances in the blood, and are seen in the following diseases:—(1) *Chronic lead poisoning*, often before any other sign or symptom appears. (2) *Malaria*—They are also to be found in Europeans long resident in the tropics, who have not suffered from malaria; but in such cases the granules are larger and not so numerous as in malaria. (3) *Mang fevers*, as he found it in mice, in which he produced a high temperature artificially. (4) *Pernicious anemia* and *late lymphadenoma* and *leukemia*, but not in chlorosis. (5) *Cancer of stomach or intestine*, where absorption takes place. (6) *Septic diseases*—It was absent from phthisis pulmonalis, unless suppurating cavities were present. A number of other diseases, such as syphilis, mercurialism, chronic nephritis, chronic hepatic diseases, diabetes, typhoid and diphtheria, do not cause it.

Micro-organisms of Vaccine Materials.

J. B. BUIET records his experiments made in the course of the last fifteen years to determine the cause of opacity of vaccine lymph. All he is prepared to say is that this opacity was due to spores from unknown sources, of a yellow, brown, white, or orange color, even in specimens which had been kept fifteen years. These he regards as the active ingredient of the lymph. Some authorities have isolated these spores and inoculated them into calves, the virus from which would "take in children, but direct inoculation of the spore products into the human being were failures.—*New York Med. Rec.*

Acid-resisting Bacilli in the Lower Animals.

MURRAY COWIE (*Jour. Exper. Med.*) communicates a preliminary study on this subject, in which he comes to the following conclusions:—(1) Acid resisting bacilli are found in many of the lower animals, more especially the horse, cow, dog, guinea-pig, and white rat. In the case of the rabbit and cat no such organisms were detected. (2) Many of these acid-resisting bacilli resemble the tubercle bacillus and the smegma bacillus of man. (3) The acid-resisting organisms are undoubtedly of different species, and there is good reason to believe that the term smegma bacillus denotes not a definite species, but rather a group of bacilli having common staining properties. His results need not be given here in more detail, except in the case of the cow, as they go to still further demonstrate the comparative difficulty and unreliability of all attempts to demonstrate microscopically the presence of tubercle bacilli in milk. In the cows chosen there was no evidence of any tuberculous or other disease of the teats or udders, and they had passed the tuberculous test. Scrapings from the moistened teats were stained as for the tubercle bacillus, and many bacilli were found, some of which resembled the tubercle bacillus very closely. Prolonged exposure to the acid did not cause their decolorization. In all, eight cows were examined for acid-resisting bacilli, with positive results in five, negative in three. Eight preparations were made from the sediment obtained from a centrifugal separator. Each specimen showed many acid-resisting bacilli, some of which might easily be mistaken for the tubercle bacillus, particularly if decolorization with methylated spirits was not employed. COWIE'S results serve to strongly support the opinion of experts, that the only reliable method of detecting the tubercle bacillus in milk is by animal inoculation.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Prophylactic Measures in Malarial Districts.

FERMI and LUMBAO (*Centralbl. f. Bakteriöl. u. Parasitenk.*) describe the measures adopted for freeing the town of Sassari from mosquitoes. There is first the search for the larvæ. They were most frequently found in the cellars, cisterns, washing-troughs in the yards, etc., of houses known to be infested with mosquitoes. They observed that in winter *Culex pipiens* generally laid its eggs in the cellars or cisterns, on account of these places being warmer at that season. In the case of water not used for drinking purposes they used petroleum oil, 5 c.c. for each square metre of surface. This spreads uniformly over the surface, forming a thin impermeable layer, quite sufficient to prevent the larvæ breathing. In summer, owing to evaporation, the protective covering did not last more than six days, but since the larvæ take fifteen to twenty days to develop, the layer of petroleum need not be renewed oftener than once a fortnight. In cisterns and wells with drinking water they used the powdered chrysanthemum flowers, as recommended by CELLI, and with excellent results.

For killing the fully formed mosquitoes in a house, they found gaseous chlorine the best means, but it could only be used in cellars, unoccupied houses, or when the house could be vacated for some hours during the day. In dwelling-houses they prefer fumigation by means of setting fire to a mixture of ground chrysanthemum, pellitory, valerian, and saltpetre. The mosquitoes were found on the walls of the cellars or in corners near the windows. In sleeping or living-rooms they searched for them near the bed and windows. Sometimes they only found them by setting fire to the fumigating powder, which brought out the mosquitoes from concealment to the windows, evidently in the hope of escaping.

The results got at the prison settlement of the Island of Asinara near Sardinia are striking. (*Ztschr. f. Hyg. u. Infektionskrankh.*) Larvæ were killed by petroleum oil; horse ponds and surface wells were pumped dry every ten or fifteen days to keep the surface soil as dry as possible. In the houses of the officials, etc., the chrysanthemum powder was burned to kill the mosquitoes, but in the cells, etc., of the prison, chlorine was developed from chloride of lime and sulphuric acid. The cells were large, and suited for about forty occupants, and were vacated by the prisoners during the whole day. For preventing the entrance of mosquitoes, a strong durable curtain, stretched on a frame, was placed in front of each window space. Each morning the chambers were treated with chlorine gas, then after an hour or two the windows were opened for ventilation.

The following are the results:—Total absence of *anopheles* from any of the rooms, and a great decrease in the numbers of *C. pipiens*. There were no newly infected cases of malaria, while in the previous year there were forty such cases.

MATTEI (*Centralbl. f. Bakteriöl. u. Parasitenk.*) describes a very successful experiment at Valsavia, a railway station on the line from Catania. It is situated in a strongly malarial district, consisting for the most of clayey land under cultivation, and apt in dry weather to become cracked and fissured, and these fissures, by the over-flowing of the river or heavy rainfall, are readily converted into pools. Towards evening the mosquitoes come out, and increase greatly as twilight sets in. The numbers are so enormous that they appear to form clouds, and, entirely surrounding the person, make successful attempts at protection very

difficult. The time of year (October 7 to November 8) most favourable for malarial attack was chosen. The weather was warm, and as the first rain of the season had fallen, the soil was being prepared for sowing. This time is always dreaded by the inhabitants.

The experiment was carried out in a large shed, built directly on the ground, and with its windows and doors replaced by wire-netting, fine enough to keep back any mosquitoes. It was conducted on four men, between 35 and 45 years of age, none of whom had ever suffered from malaria, and whose blood was from time to time during the experiment examined for the malaria parasite, but always with negative results. They travelled daily to and from Catania, where they were employed on the railway. They entered the shed about six in the evening and left about eight in the morning. The inside of the shed was whitewashed to facilitate the detection of any mosquitoes that might get in, either on the men themselves or on opening the door for their entrance. Immediately on entering for the night, the walls, bedding, etc., were examined for mosquitoes, some insect powder was burnt, and the inmates rubbed their bodies with turpentine as an additional precaution. None of the men were attacked with malaria, and though kept under supervision for four months after the experiment, none of them showed any symptoms.

Both *C. pipiens* and *anopheles* are found at Valsoria.

Meat Eating vs. Tuberculosis.

EXPERIENCE at the Zoological Gardens seems to indicate that meat eating is a good preventive of tuberculosis, but that this is not a final conclusion is evident from the fact that some of the meat eating animals do die of this disease. The figures are as follow:—The disease afflicts animals nearly half again as much as birds. The mortality from tuberculosis among the herbivorous animals is 26 per cent., while among the carnivora only 3 per cent.; of the grain-eating birds 30 per cent. succumb to the disease, as against only 11 per cent. of the meat-eaters. It is possible that, wholly aside from the natural diet, there is an original inherent protection against tuberculosis in meat-eaters that the herbivora do not possess, or it is possible that the animal food of the carnivora contains some antitoxine that vegetables are devoid of.

Examination of Stomach Contents.

B. A. BASTENO states that the simplest and best test-meal consists of a good-sized hard breakfast roll without butter, taken on an empty stomach. The roll should be thoroughly chewed and washed down with twelve ounces of water. At the end of an hour a stomach-tube is passed. If fermentation is present, there is a layer of foam on the surface, and there is an odor of butyric and other fatty acids. Mucous may be noted by lifting it up on a loop of wire. Of the filtered contents, 5 c.c. is placed in a porcelain dish with a drop or two of one-half of one per cent. alcoholic solution of dimethyl-amido-azobenzol. If this becomes pink, it indicates the presence of free hydrochloric acid. The Congored test may then be tried. If blood is suspected, it may be tested for by adding glacial acetic acid and then ether to a bit of stomach contents. The mixture should be shaken, set aside, and the ether poured off. To this ether should be added a few drops of tincture of guaiac and then a like amount of peroxide of hydrogen. A dark-blue color indicates blood. The writer then indicates the proper diet for various conditions of abnormal acidity. A suspected ulcer contraindicates the use of the stomach-tube, in which case the vomitus may give valuable information.—*Medical News*.

THERAPEUTICS & PHARMACOLOGY.

Venesection in Heat-stroke.

C. KLEIN (*Munch. med. Woch.*) observed a case of heat-stroke where venesection gave prompt relief. A powerful, temperate, and healthy coal-heaver, aged 28, acted temporarily as stoker on boardship. After a few hours' work he suddenly became unconscious and was seized with violent general convulsions. He was brought on deck, ice was applied, and artificial respiration was carried out as far as the convulsions permitted. Chloroform inhalation was tried, but abandoned, as it had a bad effect on the respiration. The convulsions increased in violence, and four sailors could hold the man with difficulty. The pulse, at first hard and full, became thready and intermittent; the respiration became more and more laboured, and there was great cyanosis. The man was evidently dying of oedema of the lungs; KLEIN therefore abstracted about 8 ounces of blood. The effect was immediate; the pulse and respiration improved, the convulsions gradually ceased, and the cyanosis was replaced by pallor. After a ten-hours' peaceful sleep the patient awoke weak, but hungry, and in a few days had recovered completely.

Use and Abuse of Potassium Iodide in Ophthalmic Practice.

THE following conclusions are presented by ALBERT RUFUS BAKER: (1) Iodide of potassium should generally be administered in rapidly increasing doses until from gr. i.-d. is given daily. (2) The drug should always be given after eating, and well diluted with water. (3) Frequent hot baths are essential to the best results in the use of the remedy. (4) Not infrequently large doses will be tolerated when smaller ones cannot be well taken. (5) The use of the large dose is not limited to syphilitic cases. (6) Large doses are indicated in optic neuritis, ocular paralysis, choroiditis, serous iritis, and in relapsing iritis, cyclitis, and interstitial keratitis. (7) It is contraindicated in gray atrophy of the optic nerve and in most cases of post-neuritic atrophy. (8) Albumin in the urine, generally speaking, is a contraindication for large doses of iodide. (9) Young children do not take the iodide kindly, and it should be administered cautiously. (10) The remedy is of doubtful value in early syphilitic iritis. (11) Large doses are of doubtful utility in the removal of post-operative exudates, but should be given further trial.

Formalin in Hyperidrosis of the Feet.

ADLER (in the *Therapeutical Supplement of the Deutsche medicinische Wochenschrift*) recommends undiluted formalin as the best treatment for perspiring feet. The feet should be well painted with or soaked in formalin for a few minutes and then allowed to dry in the air. Perspiration is entirely suppressed, owing to cauterisation, or rather tanning of the epithelium lining the sweat glands. The treatment is inapplicable where there is redness and maceration of the skin, as it causes burning, which makes walking difficult. As the thin cauterised layer peels off in about four weeks, and the subjacent regenerated epithelium begins to sweat again, the process requires repetition. As a rule, it is best to paint only the soles, as the interdigital folds bear the formalin badly. If they also are the seat of hyperidrosis, they should be treated with tannoform as a dusting power. If the soles also are macerated, they should be treated with tannoform till sufficiently hardened to bear the formalin.

Diabetic Coma.

Dr. JOHN S. ELY (*Yale Medical Journal*) says: "I would warn against too precipitate withdrawal of carbohydrates from patients suffering from diabetes. In a number of cases this has been speedily followed by the development of coma, probably because of the readiness with which proteid food yields acids in the course of its decomposition. To avoid this, the alkaline treatment should be instituted prior to the reduction of carbohydrates, and these should then be gradually withdrawn."

For Painful Dentition.

The following prescription is recommended in the *Gazzetta degli Ospedali* for painful dentition:—

R Citric Acid	each	...	2,350	grains.
Distilled Water		...		
Cocaine Hydrochloride		...	1½	"
Syrup		...	800	"
Tincture of Vanilla		...	11	drops.

M. To be rubbed on the gums.

Sealey's Pile Ointment.**TAKE OF—**

Sulph. morphia	3	gr.
Tannin	48	gr.
Pine tar	72	gr.
White wax	72	gr.
Benzonated lard	786	gr.

Mix. —*Secret Nostrums and Systems.*

Thompson's Eye Water.**TAKE OF—**

Zinc sulphate	20	gr.
Copper sulphate	5	gr.
Tinct. saffron	2	dr.
Tinct. camphor	1	dr.
Rose water	8	oz.
Dist. water	8	oz.

Mix and filter. —*New Remedies.*

Hair-Wash.

Sodium chloride	77	"

Mix. 14 grs. to 6 ozs. of water.—*Chemist and Druggist.*

Correspondence.**THE CIVIL MEDICAL DEPARTMENT.**

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—It has been said that when the employés of any great department of the State suffer from a grievance, and when their complaint is a well-founded one, the public press must voice it forth and insist upon the necessary remedy.

Is not then the Civil Medical Department's great State department, and have the Civil Assistant Surgeons no complaints? A letter from "TOMTIT, M.B.," published in the *Indian Medical Record* of the 26th September, puts forth some of these complaints; but it has elicited no response, either from the editor, or the press in general, that I know of. The complaints that are mentioned there have been more or less fully discussed by the writer, and I will not say more than a few words upon these heads. The rule about the promotion examination from the second to the first grade of Assistant Surgeons affects them more seriously than it would appear at first sight. The rule is specially hard, as it benefits nobody, except perhaps the Government.

Under the former regulations every Assistant Surgeon could appear in the examination as a matter of right, if he had completed seven years' service in the second grade. But now he must be recommended. Here creeps in a chance for favouritism. Not to speak of the injured ones, of what avail would favouritism be to the favourite? He must complete his seven years, and then he must pass the usual test examination as under the old régime. He must do all he had to do before and something more.

The working hours of the dispensary are fixed; but there is a "but" in the case. The Assistant Surgeon in charge has to see urgent cases whenever required, whether it be noon or midnight. No medical man will, I hope, complain of this; but often no consideration whatever is made, and ordinary patients and prescriptions come regardless of the specified hours, and the Civil Surgeon usually sees no reason why they should not be attended to just when they come in. What does all this mean? A Civil Assistant Surgeon has to work every day of the year—there is no holiday for him. All his days are Mondays—Sundays have been struck off his diary. Unless he has a strong and reasonable Civil Surgeon, he has to remain chained to the rickety dispensary chair every minute of the 24 hours; and if he leaves it, he does so at the risk of displeasing not only his own immediate superior, but probably the whole staff of civil officers. There is not a single minute of his time which may be called his own. He is a prisoner, though lodged in the asylum for the infirm.

Were all these points taken into consideration when the rules for his pay and other emoluments were framed? Because he is overworked, is he entitled to any advantage as regards his leave? I fear the answer to this cannot be a same rule as simple "No." Previously he was under the regards leave as other civil officers. He had no advantage; but then he had no disadvantages either. But by a recent circular of the Inspector-General of Civil Hospitals, Punjab, the rules have been somewhat modified for medical subordinates. The Civil Surgeons now have not the power, which they formerly had, of granting casual leave to Assistant Surgeons and Hospital Assistants without the previous sanction of the Inspector-General, unless there is another medical man on general duty (which is rarely the case) who can work the dispensary during the days of leave. And then in no case is the leave to extend to more than seven days at a time (the limit was ten days formerly, as for other departments). This circular practically does away with all casual leave for medical subordinates. The arrangement, as laid down in the circular, is out of the question in mofussil towns, and so there would be no casual leave for them. The Civil Assistant Surgeons now only look forward to a supplementary circular to cut short or do away with their privilege leave to complete their discomfiture, as, according to the circular, Government cannot incur any extra expenditure in granting leave.

Now, as the Civil Assistant Surgeons will have no holidays throughout the year, and do not grumble, the India Government, more solicitous of their health than they themselves seem to be, has ruled that in future their grade examinations would only be held once in the year instead of twice, as was formerly the case, and as is probably the case even now in all the other departments. The reason assigned for this departure is that it has been represented that the month of May is hot for these examinations. Does it not show the care of a parent for a silly child? But the same benevolent Government never raised its motherly voice when the examination date of the Lahore Medical College was changed from the month of March to that of the third week of June. Do not medical students feel the heat of June while appearing in their University examinations (which is far more stiff than the departmental examination of the Assistant Surgeons)? To explain this anomaly—the heat theory—I fear, will not do. Now that the examination will only be held in November, those Assistant Surgeons who are unfortunate not to pass it then will have to wait for the cool days of November again and thank the Government. The loss of a few hundreds of rupees which they suffer by this arrangement they can credit to the account of heat. How far these arrangements

shall benefit the Assistant Surgeons is quite apparent. The only outcome of these regulations will be to make the department less attractive. In these days of struggle for existence, there would be no lack of persons to take up the profession, but able men will be attracted to more paying lines, and the Government will obtain a cheap medical department at the expense of efficiency. It is said that though their work is hard and pay inadequate, medical men have the advantage of private practice; but it is merely an illusion. Those who have entered the department know probably too late what private practice means, and what can it bring to the man's pocket. It might be a source of income to a fortunate few; but to the average Assistant Surgeon, posted to a small station, it is almost an unknown luxury. If an Assistant Surgeon comes to compare his own prospects with those of a former friend and class fellow not more hard-working and intelligent than himself, he becomes disheartened. Not to think of the longer technical course of study with all its hardships, he finds himself placed at a great disadvantage. Though he may find that he has a high official status, he knows that he has not the means to maintain it.

Yours, &c.,

CIVIL ASSISTANT SURGEON.

(The complaints were commended for consideration.—ED., I.M.R.)

THE BRUSSELS M. D.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—I quite agree with what your correspondent, "NOT A BRUSSELS GRADUATE," has written in your issue of the 9th January regarding the "M. D. of Brussels. I have not seen the letter of "M. D." referred to, and so do not know the nature of the strictures made by him. I have just returned from Europe, and have taken both the "triple qualifications" of Edinburgh and the M. D., Brux., and I have no hesitation whatever in asserting that I found the latter more difficult. It was fortunate that I was well up in all my subjects, having just gone through the L. R. C. P., &c., of Edinburgh, which I passed with great credit. There were five gentlemen, all M. R. C. S., L. R. C. P. of London, who went in for the examination with myself. Of these, three were thrown out in the very first doctorate. The other two just managed to "scrape through," as the school-boy would say. Neither passed *with credit*, though amongst the passed candidates three passed *with great credit*. This should be sufficient to convince people that you must know your subjects, and know them well, if you want to pass, and like all European Universities, if the examiners find that you possess a good knowledge of your subject, they pass you; if not, you get plucked.

Yours, &c.,

M.D.ICO.

A GOOD OR BAD BARGAIN IN A BINAURAL STETHESCOPE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—We beg to advise despatch to your address a Binaural Stethoscope which we are supplying to our customers, and none has complained. You can see yourself whether they are worth the money paid for them. Your correspondent, "A SUFFERER," cannot expect a Binaural Stethoscope like those of ARNOLD's or HICK's of £1 or 15s. for one rupee. The stethoscope sent to your correspondent might have broken in transit, for which he could have it replaced by referring to us. We are very sorry for your "A SUFFERER" for the loss of the sum of one rupee, on account of the carelessness of the post-office or of the packing. We leave our case in your hands, and shall be very thankful to you if you will kindly give your opinion in your valuable paper.

Yours, &c,
B. M. NARAIN & Co.

EGERTON STREET, DELHI;
22nd January 1901.

(We have seen the Stethoscope sent out by this firm, and we are satisfied that the article given is a fair return for the money asked.—ED., I.M.R.)

THREATENED SUIT FOR DAMAGES AGAINST THE EDITOR, INDIAN MEDICAL RECORD.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—Your attention might have been drawn to a letter which appeared in a recent number of *Civil and Military Gazette* of Lahore, written in a most unbecoming style, frightening you with a suit for damages in the High Court of Calcutta. If Mr. GUNGADIN carries his foolish threat into execution, you will have to go through a harassing and expensive case. You deserve the gratitude of the whole profession for your endeavours to uphold its interest. I doubt not also that both Government and the public will support you. I would ask the President of the Indian Medical Association to start a "Wallace Defence Fund" at once and circulate the list. I appeal to all members of the profession, independent practitioner and service men to subscribe, and thereby practically show their sympathy with a member of their profession who is prosecuted for trying to uphold the cause of their profession in India.

Yours, &c.,
SYMPATHY.

(We have not seen the letter referred to. We are content to wait and watch events. When the event of Gungadin versus the *Indian Medical Record* comes off, we shall be found ready. Meanwhile our brethren may withhold their subscriptions.—ED., I.M.R.)

Government Medical Gazettes.

BENGAL.

Asst. Surgn. Nobin Chunder Dutt is promoted to the Senior grade from the 24th July 1900.

Mily. Asst. Surgn. J. E. L. Chinal is apptd. to act as a Mily. Asst. Surgn. attached to the Presdy Gen. Hosp., Calcutta, during the absence, on deputation, of Mily. Asst. Surgn. P. Victor.

Asst. Surgn. Syed Hassan is apptd. to do supy. duty at the Med. Col. Hosp., Calcutta, from the 12th Nov. 1900.

Asst. Surgn. Harendra Kumar Das of the Cholera Emigration Hosp. at Naibati, is allowed leave for three months, on med. certificate, from the 13th Nov. 1900.

BOMBAY.

Mr. Alfred John Hesterlow to act as Civil Surgn., Chittoor, during the employment of Major C. Adams, I.M.S., on other duty.

CENTRAL PROVINCES.

Civil Hosp. Assts. Balwant Lakshman and S. Venkatesan, on plague duty in the Nagpur City, are directed to do gen. duty under the orders of the Civil Surgn., Nagpur, from the 1st Oct. 1900.

Civil Hosp. Asst. Balwant Lakshman, doing duty under the orders of the Civil Surgn., Nagpur, is temply. posted to the Buti Branch Dispy., Nagpur, during the absence, on privilege leave, of Civil Hosp. Asst. Abdul Majid Khan.

The services of Civil Hosp. Asst. Suresh Chandra Chatterji being no longer required by the P. W. Dept., he is deputed on famine duty in the Civil Dept., in the Raipur Dist.

The services of Civil Hosp. Asst. Rattan Chand being no longer required by the P. W. Dept., he is deputed on famine duty in the Civil Dept., in the Raipur Dist.

The services of Civil Hosp. Asst. Sarat Kumar Mitra being no longer required by the P. W. Dept., he is directed to do gen. duty under the orders of the Civil Surgeon, Nagpur.

The services of Civil Hosp. Asst. Behari Lal Sen being no longer required by the P. W. Dept., he was directed to do gen. duty under the Civil Surgn., Chhindwara, from the 17th Sept. to the 21st Oct. 1900.

Privilege leave for three months is granted to Civil Hosp. Asst. Kabil Ahmed, on famine duty in the Civil Dept. in the Bhandara Dist., from the 10th Nov. 1900.

The services of Civil Hosp. Asst. Muhammed Inamullah being no longer required by the P. W. Dept., is transferred on famine duty under the Civil Dept. in the Sangor Dist.

Privilege leave for three months is granted to Civil Hosp. Asst. Kashi Nath Gopal from the date he is relieved of famine duty in the Civil Dept. in the Nagpur Dist.

Civil Hosp. Asst. Abdullah Bhat, whose services are no longer required for famine duty in the Civil Dept., is directed to do duty under the orders of the Civil Surgn., Nimar.

Civil Hosp. Asst. Surji Rao, on famine duty in the Civil Dept. in the Balaghat Dist., is directed to do duty under the orders of the Civil Surgn., Nagpur.

Civil Hosp. Asst. Ashraf Hussain, whose services were not required by the P. W. Dept., for famine duty, was directed to do duty under the orders of the Civil Med. Offr., Balaghat.

Civil Hosp. Asst. Ashfaq Hussain, on gen. duty at Balaghat, was transfd. in the same capacity to Nagpur.

Civil Hosp. Asst. Krishna Chander Burns, whose services were not required by the P. W. D. for famine duty in the Balaghat Dist., was ordered to do duty under the orders of the Civil Surgn. of Nagpur.

Civil Hosp. Asst. Jotindranath Ghose is directed to do duty under the orders of the Civil Surgn. of Nagpur.

Civil Hosp. Asst. Abdullah Bhai, doing duty under the orders of the Civil Med. Offr., Nimar, is apptd. to the Harsud Branch Dispy. in that dist.

Civil Hosp. Asst. Raghunath Parshad, attached to the Harsud Branch Dispy., is granted three months' privilege leave from the date on which he is relieved of his duties by Civil Hosp. Asst. Abdullah Bhai.

Civil Hosp. Asst. Ramsundar Lal, doing duty under the orders of the Civil Surgn., Nagpur, is apptd. to the Deoli Branch Dispy. in the Wardha Dist.

On being relieved of the ch. of the Deoli Branch Dispy., Civil Hosp. Asst. Wahid-ud-din is apptd. to the Hinganghat Branch Dispy. in the Wardha Dist.

Civil Hosp. Asst. Mohan Lal, attached to the Hinganghat Branch Dispy., is granted furlough for one year from the date he is relieved of his duties by Hosp. Asst. Wahid-ud-din.

The services of the Civil Hosp. Assts. named below being no longer required for famine duty in the Civil Dept., they are directed to do duty under the orders of the Civil Med. Offr., Chanda:—

Vithal Raghoba Lande; Maroti Ramkrishna; Armodaya Phatak.

Civil Hosp. Assts. Maroti Ramkrishna and Vithal Raghoba Lande, on gen. duty at Chanda, are transferred in the same capacity to Nagpur.

Civil Asst. Surgn. Bipin Bihari Gupta, doing duty under the orders of the Civil Surgn., Nagpur, is attached temp. to the Chief Commr.'s Camp.

Privilege leave for three months is granted to Asst. Surgn. Samuel Jay, Najf Kotak, Inspr. Med. Offr., Chanda, from the date on which he may be permitted to avail himself of it.

Privilege leave for three months is granted to Mr. Harnam Das, Asst. Surgn., Bilaspur, from the 1st Dec. 1900, or any subsequent date on which he may avail himself of it.

The services of Civil Hosp. Asst. Radha Kristo Das being no longer required by the P. W. D., he is deputed on famine duty under the Civil Dept. in the Sambalpur Dist.

Civil Hosp. Asst. Radha Kristo Das, on famine duty in the Civil Dept. in the Sambalpur Dist., is directed to do gen. duty under the orders of the Civil Med. Offr. of that dist.

Civil Hosp. Asst. Radha Kristo Das, on gen. duty under the orders of the Civil Med. Offr., Sambalpur, is transferred in the same capacity to Raipur.

The services of Civil Hosp. Assts. Shaikh Amanat Hussain and Anand Ram Nanda being no longer required for famine duty under the Civil Dept. in the Sambalpur Dist., they are directed to do duty under the orders of the Civil Med. Offr., Sambalpur.

Civil Hosp. Assts. Shaikh Amanat Hussain and Anand Ram Nanda, doing duty under the orders of the Civil Med. Offr. Sambalpur, are transferred in the same capacity to Raipur.

Civil Hosp. Asst. Dada Lakshman Silkey, on famine duty in the Civil Dept., in the Raipur Dist., is directed to do duty under the orders of the Civil Surgeon of that dist.

Civil Hosp. Asst. Baliram, whose services were not required for famine duty in the Civil Dept., was directed to do duty under the orders of the Civil Surgn., Nagpur.

Civil Hosp. Asst. Sadashiv Narayan, attached to the Poor-house at Sambalpur, is directed to do duty under the orders of the Civil Med. Offr. of that Dist.

One month's leave on med. certificate is granted to Civil Hosp. Asst. Kahirode Kumar Ghose, in extension of that granted him in Dept. Order dated the 10th Oct. 1900.

Civil Hosp. Asst. Ramkrishna Appaji, attached to the Murwara Branch Dispy., Jabulpore, is granted three months' privilege leave from the date on which he is permitted to avail himself of it.

Civil Hosp. Asst. Beni Parshad, attached to the Sehora Branch Dispy., Jabulpore, is apptd. to the Murwara Branch Dispy. during the absence on leave of Ramkrishna Appaji.

Civil Hosp. Asst. Ramkrishna Palkaji, doing duty under the orders of the Civil Surgn., Hoshangabad, is temp. apptd. to the Sehora Branch Dispy., Jabulpore, vice Beni Parshad, transferred to Murwara.

Civil Hosp. Asst. Ramsunder Lal, doing duty under the orders of the Civil Surgn., Nagpur, is apptd. to the Jail Hosp., Chanda.

On being relieved of the ch. of the Jail Hosp., Chanda, Civil Hosp. Asst. Inam Khan is apptd. to the Hinganghat Branch Dispy. in the Wardha Dist.

Civil Hosp. Asst. Abdul Khaliq was directed to do duty under the orders of the Civil Med. Offr., Balaghat, from the 17th Oct. to the 6th Nov. 1900.

The services of Capt. P. F. Chapman, M.B., B.S. (Bengal), are placed permanently at the disposal of the Honourable the Chief Commr. of the C. P., from the 15th June 1899.

The services of Civil Hosp. Asst. Keshoo Raghunath Das being no longer required for famine duty in the Saugor Dist. under the Civil Dept., he is transferred to Nagpur for gen. duty under the Civil Surgn. of the latter dist.

The services of Civil Hosp. Asst. Muhammad Inamulla being no longer required for famine duty under the Civil Dept., in the Saugor Dist., he is directed to do gen. duty under the orders of the Civil Surgn. of that dist.

Civil Hosp. Asst. Mohendra Nath Mukerjee, doing duty under the orders of the Civil Surgn., Betul, is transferred in the same capacity to Hoshangabad.

The services of Civil Hosp. Asst. Nilkant Narayan being no longer required by the P. W. D. for famine duty, he is re-apptd. to the Police Hosp., Raipur.

Civil Hosp. Asst. Nilkant Narayan, attached to the Police Hosp., Raipur, is directed to hold ch. of the Poor-house at that stn. in addition to his own duties.

The services of Civil Hosp. Asst. Sadashoo Narayan being no longer required for famine duty in the Civil Dept. in the Sambalpur Dist., he is directed to do gen. duty under the orders of the Civil Med. Offr. of that dist.

Civil Hosp. Asst. Sadashoo Narayan, doing duty under the orders of the Civil Med. Offr., Sambalpur, is directed to hold ch. of the Poor-house in that town.

Civil Asst. Surgn. Krishnaji Kashinath Gokhle, in Civil Med. Ch. of the Chanda Dist., to the executive and med. ch. of the Chanda Jail.

Civil Hosp. Asst. Hashmat Ali was on gen. duty at Balaghat from the 22nd Oct. to the 9th Nov. 1900.

N.-W. P. & OUDH.

Civil Asst. Surgn. Har Parshad, attached to Sadr Dispy., Fyzabad, privilege leave for one month and 22 days from 19th Jan. 1901, or any subsequent date.

Civil Asst. Surgn. S. M. Abdul Rahman, attached to Chakrata Dispy., privilege leave for one month from 10th Jan. 1901, or any subsequent date.

Civil Asst. Surgn. Rama Prasad Bagchi, M.D., Lecturer on Med. Jurisprudence and Morbid Anatomy, Agra Med. School, privilege leave for 45 days from the 26th Jan. 1901.

Civil Asst. Surgn. Chandra Mohan De, Asst. Health Offr., Agra, privilege leave for one month from the 6th Dec. 1900.

Temp. Civil Asst. Surgn. Kashi Nath, on reserve duty at Lucknow, to Allahabad for duty in the Magh Mela Hosp.

Civil Asst. Surgn. Baij Nath Vias, on being relieved of the off. ch. of the Fatehpur Sadr Dispy., to reserve duty at Lucknow.

Civil Asst. Surgn. Baij Nath Vias, on reserve duty at Lucknow, to the ch. of the Sadr Dispy., Fyzabad, as a temp. measure, vice Asst. Surgn. Har Parshad.

Civil Asst. Surgn. E. H. Thomas, M.B., on being relieved of the off. ch. of the Thomson Hoop, and Leckner on Materia Medica, Med. School, Agra, to officiate as Lecturer on Med. Jurisprudence and Morbid Anatomy, Med. School, Agra, during the absence on privilege leave of Civil Asst. Surgn. Rama Prasad Begshi, M.D.

Hosp. Asst. Joti Parbhad, in ch. of the Awarah Branch Disp., in the Etah dist., is temp. deputed to the ch. of the Sadr Disp., Etah, from the 22nd Dec. 1900.

Civil Asst. Surgn. Chandra Mohan De, on return from leave, to Lalitpur Disp. in the Jhaasi dist.

Civil Asst. Surgn. Gura Prasanna Raha, in ch. of Sadr Disp., Etah, is apptd. as Asst. Health Offr. in connection with plague at Agra, from the 22nd Dec. 1900, as a temp. measure.

Civil Asst. Surgn. Ghulam Mustafa, from the ch. of the Sadr Disp., Muzaffarnagar, to plague duty in connection with Hadjra Camp at Allahabad, as a temp. measure.

Civil Asst. Surgn. Chaman Singh, attached to Lalitpur Disp. in the Jhaasi dist., to plague duty at Allahabad, in connection with Magh Mele.

Temp. Civil Asst. Surgn. Sarat Chandra Chakravarti, on reserve duty at Meerut, to the ch. of the Sadr Disp., Muzaffarnagar, as a temp. measure.

Hosp. Asst. Nihal-ud-din, attached to the Jail and Police Hosps., Muzaffarnagar, held ch. of the Sadr Disp. there, in addn. to his own duties, from the 22nd to 31st Dec. 1900.

Civil Asst. Surgn. Gobind Chandra Banerji, attached to the Sadr Disp., Unao, held civil med. ch. of that dist., in addn. to his other duties, from the 16th Nov. to the 16th Dec. 1900.

Mil. Asst. Surgn. W. Heatboock, in civil med. ch. of Unao, was on leave on med. certificate, from the 16th Nov. to the 16th Dec. 1900.

With effect from the 16th July 1900, *vice* Lieut.-Col. E. Mair, transferred to Bengal, Major W. H. Gray, I.M.S., Offg. Supdt., Central Prison, Benares, to be confirmed in that appt.

Major J. J. Pratt, I.M.S., Civil Surgn., from the med. ch. of the Camp of His Honor the Lieut.-Govr. and Chief Commr. to the Naini Tal Dist., from the 8th Jan. 1901.

Mil. Asst. Surgn. L. J. O'Reilly, on plague insp. duty at Dehra Dun, to hold ch. of the civil med. duties of the Bulandshahr dist. as a temp. measure.

Capt. Gordon Travers Birdwood, M.D., I.M.S., Med. Offr., is transferred to the supy. list from the 1st Dec. 1900.

Major William George Patrick Alpin, M.D., I.M.S., supy. list, is retransferred to the active list from the 1st Dec. 1900.

PUNJAB.

Hosp. Asst. Badha Kieban, while employed on plague duty, Jullundur Dist., was granted leave on med. certificate from the 8th May 1900. On the termination of this leave he was placed on gen. duty at the Jullundur Civil Hosp. on the 22nd Nov. 1900.

Muhammad Ismail is admitted into the service as a temp. Hosp. Asst. for employment on plague duty in the Jullundur and Hoshiarpur Dist. from the 16th Dec. 1900.

Hosp. Asst. Ram Chand, doing itinerating duty in the Hissar Dist., was apptd. to the ch. of the Bahadurgarh Disp., Rohtak Dist., on the 5th Dec. 1900.

Hosp. Asst. Ali Ahmad, doing gen. duty at Jullundur, was transferred for gen. duty to the Jalaipur Disp., Gujrat Dist., on the 11th Dec. 1900.

Asst. Surgn. Umrao Raja Lal reported himself to the Civil Surgeon, Karnal, for gen. duty on the 18th Dec. 1900.

On being relieved of his duties on the Upper Sutlej Inundation Canals, Hosp. Asst. Khuda Baksh was granted privilege leave for 3 months and 17 days from 1st Oct. 1900.

Hosp. Asst. Khuda Baksh was apptd. to the subordinate ch. of the Civil and Police Hosps., Jullundur, from the 17th Dec. 1900.

On transfer from Lahore, Hosp. Asst. Kale Khan was apptd. to the ch. of the Jail and Police Hosps., Hoshiarpur, on the 4th Dec. 1900, relieving Hosp. Asst. Ram Rattan.

Hosp. Asst. Isbar Das, Rajipur Disp., Hoshiarpur Dist., was granted leave on med. certificate for one month, and was relieved of his duties on the 6th Dec. 1900, by Hosp. Asst. Ram Rattan, transferred from Hoshiarpur.

On being relieved of the ch. of the N.W. By. Hoop, Umballa Cantonment, Hosp. Asst. Harman Singh was apptd. to the Kotgarh Disp., Simla, Dist., on the 4th Dec. 1900.

Hosp. Asst. Abdul Rahim, Amritsar Police Hoop, held ch. of the Jail and Lock-up Hosps., Amritsar, from the 1st to the 5th Oct. 1900, in addition to his own duties, during the absence of Hosp. Asst. Abdulla Khan, on privilege leave.

Hosp. Asst. Fakir Chand, doing gen. duty at Rawalpindi, was transferred to Gujrat for gen. duty on the 25th Oct. 1900.

Hosp. Asst. Dasaundhi Khan, Jhetum Canal Disp., Rawul, has obtained three months' privilege leave, and was relieved of his duties on the 26th Nov. 1900 by Hosp. Asst. Fakir Chand, transferred from Gujrat.

Hosp. Asst. Jaggan Nath, doing gen. duty at Lahore, was apptd. to the Buchiana Disp., Chenab Canal, Upper Gugera Divn., on the 2nd Dec. 1900, relieving Hosp. Asst. Akbar Khan.

On being relieved of his duties on the Chenab Canal, Upper Gugera Divn., Hosp. Asst. Akbar Khan was apptd. to the Central Jail Hoop, Montgomery, on the 9th Dec. 1900, relieving Hosp. Asst. Karm Chand, who was placed on gen. duty at Montgomery from the 10th Dec. 1900.

Lala Debi Chand is admitted into the service as a temp. Hosp. Asst. for employment on plague duty in the Jullundur Dist. from the 21st Dec. 1900.

The six weeks' leave on med. certificate granted to Asst. Surgn. A. Williams in *Punjab Gazette*, dated 9th Oct. 1900, has been extended by two months by Her Majesty's Secretary of State for India.

The services of Hosp. Asst. Farozedin being no longer required for itinerating duty in the Hissar Dist., he was placed on gen. duty at Hissar on the 1st Jan. 1901.

Hosp. Asst. Gandu Ram, doing gen. duty in the Gurdaspur Dist., was transferred to the Civil Hoop, Amritsar, for gen. duty on the 29th Dec. 1900.

Hosp. Asst. Abbas Ali, doing gen. duty at Karnal, was apptd. to the ch. of the Arnauli Disp., in the same dist., on the 23rd Dec. 1900, relieving Hosp. Asst. Abdulla Khan, who was placed on gen. duty at Karnal from the 29th Dec. 1900.

Hosp. Asst. Sat Ram resumed ch. of the N.W. By Disp., Saharanpore, on the 20th Dec. 1900, relieving Hosp. Asst. Khuda Baksh.

Hosp. Asst. Hussain Shah resumed ch. of the Talamba Disp., Mooltan Dist., on the 1st Jan. 1901, relieving Hosp. Asst. Gela Ram.

On being relieved of the ch. of the Karnal Sadr Disp., Asst. Surgn. Ghulam Muhammad was apptd. to do special plague duty in the Jullundur and Hoshiarpur Dist. from the 29th Dec. 1900.

DOMESTIC OCCURRENCES.

[The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.]

BIRTHS.

BORAH.—At Silohar, on Friday, the 11th of January 1901, at 10-15 P.M., the wife of Lieut.-Col. S. Borah, I. M. S., of a son.

DEATHS.

JOHNSTON.—At Loralai, Beluchistan, on the morning of the 9th January, murdered in the bazaar by a fanatic, Captain Dudley Oates Johnston, I.M.S., 24th Beluchistan Regiment, aged 30 years.

O'CONNOR.—On the 9th January 1901, at Allahabad, N.W. P., of heart failure, Georgiana, the dearly loved wife of Surgeon-Major J. O'Connell (retired), aged 54 years, 4 months and 21 days.

ORIGINAL ARTICLES.

MANAGEMENT OF DIFFICULT BREECH LABORS.*

By ADAM H. WRIGHT, B.A., M.D.,

Professor of Obstetrics, University of Toronto.

THE dangers to the child in breech labors are fairly well known, but not always duly appreciated. In the most skilled hands probably 10 per cent. of the children are still-born; in some charities, we are told by HERMAN, 30 per cent. perish during delivery. In other words, the excess in the mortality rate depending on want of skill in management sometimes amounts to 20 per cent. This is certainly a very serious matter, and is far from creditable to our modern school of obstetricians. My own experience and observation lead me to believe that many physicians neglect to use proper and systematic methods in the management of these cases. Fortunately, it happens that it is not difficult to acquire a reasonable amount of skill if we adopt certain rules in assisting delivery in breech cases. I have not time, nor any desire, to refer to all the methods which have been described by distinguished obstetricians in various parts of the world, but will endeavour to outline a definite plan of action, having reference especially to the safety of the child, and for the sake of brevity will speak in rather a dogmatic way. It is generally better to explain to the friends the nature of the case and the extra risk to the child.

Position of the Patient.—Place her on her back across the bed with buttocks at the edge of the bed, in the lithotomy or WALCHER'S position. As a general rule, I greatly prefer the dorsal position for obstetrical operations, such as forceps delivery, version, etc.; but especially do I like it in breech labors. I think it equally important that the patient should be placed across the bed, and I thoroughly endorse DURHSSEN'S remark that "in this way alone can proper assistance be rendered." Do this in multipara when the breech enters the vagina, in primipara when it is on the point of delivery (DURHSSEN).

Preparation of Physician.—Make bare both arms up to shoulders, or as nearly so as possible, and cleanse hands and arms thoroughly. The accoucheur should be prepared to pass either hand into the vagina or uterus as speedily as possible. A 1 per cent. solution of lysol is probably the best for rinsing purposes during the manipulations.

Management of Delivery.—Avoid traction on the child, if possible, because it generally causes extension of arms over the head, and frequently extension of the head itself. Before the expulsion of the breech, instruct the nurse how to press on the fundus uteri, when required, to assist in expelling the thorax and shoulders, and how to press on the head after the shoulders are born. After the delivery of the breech give the signal for patient to bear down and nurse to press on fundus. When breech does not descend into pelvis within an hour or two after the os is fully dilated, traction becomes necessary.

Bring Down a Leg.—Better to have patient anaesthetized before all the liquor amnii has escaped. Pass up the hand with its palm towards the child's abdomen. Support the uterus with other hand over fundus externally. Seize

the anterior foot if possible. "By it we can more easily pull the child downward and backward through the superior strait." When legs are extended on thighs, so that feet are close to head, pass the hand to the fundus. When you reach the knee, press it outward, then push the hand further, and seize the instep of foot, and carry it to the other side and bring it down.

When interference becomes necessary after the breech has descended into pelvis, it is better even then to pass up the hand and bring down a foot; but full anaesthesia is desirable, and great gentleness and caution are necessary.

With reference to other methods, I have but little to say. Digital traction with index finger hooked into groin, or traction with the soft fillet is sometimes sufficient, and either is quite satisfactory. The blunt hook is dangerous. The forceps is also dangerous and generally useless. When the child is born as far as umbilicus, pass the finger into the vagina and pull down a loop of cord, but do not waste any time in trying to guide the cord to any particular part of the pelvis, as is generally recommended.

Place a piece of flannel or small blanket or diaper (sterilized) round the exposed part of the child to prevent respiratory efforts which may be induced by contact with the cold air.

Liberations of Arms.—The arms are nearly always dragged over the head when traction has been employed.

When the shoulders appear at vulva, pass two fingers along the most easily accessible arm to the bend of the elbow, push it backward and bring it across the face to the vulva, first the elbow, then the arm, then the hand. Bring other arm down similarly. Be careful not to press on humerus for fear of causing fracture.

When the shoulders are arrested at the superior strait, an entirely different method is advisable.

Press the body of the child slightly upward and rotate sufficiently to bring the back to one or the other side of mother's pelvis; then elevate the hips toward mother's abdomen, using moderate traction, and try to liberate the posterior arm. Use the hand that naturally faces abdomen of child and introduce until two fingers reach elbow. Draw arm across the child's face and then downward. Then bring hips downward and make traction on thighs, as there may now be room for the head and remaining arm to emerge. If not, push child backward into pelvis and rotate the body, so that the arm that was anterior becomes posterior. During this rotation the back of the child should sweep across the front of the mother's pelvis. Bring down the second arm as before with the other hand.

During rotation be careful not to dislocate the atlas upon the axis if child be alive; but if the thorax has been pushed upward in such a way as to free the head from the superior strait, this danger is avoided.

Neckal or Dorsal Displacement of Arm.—Very rarely the arm is extended by the side of the head, and is bent at elbow, so that the forearm lies behind the neck.

Treatment.—Place child's body downward and pass fingers along the back behind symphysis, seize the elbow, and then sweep the arm outward and over fetal face. Or

* Read at the Meeting of the Ontario Medical Association, June 1899.

rotate the fetal body in a direction opposite to that which produced the displacement. It may sometimes be necessary to fracture the arm.

Delivery of the Aftercoming Head.—In no case should the head be allowed to remain in the vagina after the delivery of the shoulders one moment longer than actually necessary. The uterine contractions have now little or no expelling force, while pressure on the cord and premature attempts at respiration at this stage are especially dangerous to the child. I employ the following methods in the order named:—

1. *The Prague Method.*—Grasp the ankles with the right hand and place the left hand over the shoulders with the thumb and index finger on one side of the neck and three fingers on the other side. Pull downward and backward until head has entered the pelvis and then upward and forward, bringing the back of the child nearer to the mother's abdomen, as the face, chin first, slips over the perineum. I use the terms right and left hand for the sake of convenience. The choice of hand for each portion of the manipulation may be left to the operator. In this method the force is expended on the child's neck, and if too great, might cause dislocation or even decapitation.

In the majority of cases delivery is accomplished simply and quickly by this method, but in difficult cases, where much force is required, I adopt the VEIT-SMELLIE method. I may add that British obstetricians, as a rule, consider that the Prague method should be employed only when the head is in the pelvis.

2. *The Veit-Smellie Method.*—Leave the left hand in its position over the nape of neck. Place the right arm so that the abdomen of the child lies upon it straddle-wise. Introduce fingers with hand, if necessary, into vagina and one or two fingers into the mouth, and pull downward on the jaw to flex head, if possible, and then apply traction to both jaw and shoulder. MATTHEWS DUNCAN demonstrated that fifty-six pounds might be applied in some cases by dragging the lower jaw without appreciably injuring the parts. Let your assistant or nurse take the legs of child in one hand and hold child as far forward as you consider necessary, while she still presses over fundus with the other hand.

3. *Modified Veit-Smellie Method.*—SMELLIE first pulled on the lower jaw as described in No. 2, but when he was afraid of overstraining it, he modified the method as follows: Remove fingers of right hand from mouth, and apply them over the superior maxillary bones on either side of nose. Pull face downward, while fingers of left hand push occiput toward the hollow of sacrum. Then employ traction. If you find that you have flexed the head to any extent, place the hands as in second method and pull. The chief advantage connected with this method is the production of flexion which was formerly insufficient to allow easy delivery. It is not likely that jaw traction does much in the way of aiding flexion, but it certainly tends to prevent extension, as HERMAN expresses it. When we pull, the pressure of the brim presses the parietal bones together, and thus makes the vertex more pointed, while it lessens the transverse diameter.

Pressure from above may prevent this moulding of head, and in some cases it is better to remove this pressure after it has been applied for some time.

4. *Application of Forceps.*—When other means have failed, we may extract with forceps. Formerly this instrument was employed more frequently than now. The SMELLIE method is simpler and occupies much less time than the application of the forceps, while the power which may be used in the jaw and shoulder traction is, as a rule, quite as great as that which can be obtained with the forceps. This has been the experience during late years at the Rotunda in Dublin. However, it is well to have the forceps disinfected and at hand in all cases of breech labors, so that it may be used if necessary. The axis traction is best. The blades should be introduced and the handles locked under the body of the child, which should be held forward by an assistant, and traction should be applied on the axis of the pelvis.

5. *Perforation.*—If forceps traction, employed for a reasonable time, fails and the child is dead, consider the further possibility of damage to the soft parts of the mother, and use the perforator. This is seldom necessary unless there be some deformity of the head, especially hydrocephalus.

ORAL SEPSIS AS A CAUSE OF DISEASE.

BY WILLIAM HUNTER, M.D., F.R.C.P.

SEPSIS may arise from diseased conditions of the mouth in connection with a number of general infective processes. This condition, though frequent, is apt to be overlooked.

Case I.—A woman had suffered for ten months from gastric pain, sickness, and nausea. She was cachectic in appearance, and the symptoms were attributed to cancer, though no growth was detected. The pain was at times very severe, and the sickness usually occurred in the morning and had no relation to food. She had lost her sense of taste and had a constant bad taste in the mouth. Her teeth were absent with the exception of four stumps, from the sockets of three of which pus oozed on pressure, but her tooth-plates were clean and in good condition. The symptoms being attributed to the continual swallowing of pus, the teeth were extracted, and immediate improvement took place, but was not maintained. A severe attack of pain and vomiting occurred, and lasted about three weeks, at the end of which time a specimen of the vomited matter was found to contain blood, fibrin, leucocytes, and gastric cells with masses of pyogenic organisms—streptococci and staphylococci. The patient was now confined to bed and fed entirely on peptonised gruel, beginning with 1½ pints daily. Counter-irritation was applied to the stomach and sedatives were administered, while with the view of combating the septic condition, 3 grs. of salicylic acid were given thrice daily and continued from two to three months. Improvement was immediate and continuous. Sickness and pain were checked in 24 hours. The pulse rate and temperature fell, and in ten days she was able to go out and began to gain in weight.

The power of the stomach to destroy organisms depends on the presence of free hydrochloric acid. If there is an increased supply of organisms with diminished secretion of acid, as in gastric catarrh, septic infection of the stomach is readily set up. This is especially apt to occur from dental decay, and such patients present an ashy grey look and an air of languor often associated with distaste for food and periodic nausea. The following cases illustrate the frequency of this condition and the ease with which it may be overlooked even while the patient is being treated for the local effects.

Case II.—A woman had suffered from periodic attacks of fever and rashes which had come on at irregular intervals for two or three years. She had also marked nervous disturbances. There was a typical blotchy septic rash over the legs, arms, and body. About a month previously her dentist had removed a tooth-plate which had partly grown into her upper jaw, and which she had worn for several years.

Case III.—An old man complained of sickness, nausea, disturbance of digestion, and a foul taste in his mouth, which symptoms had lasted for 12 months. His tongue was red, and looked like a piece of raw meat, and the gums in both jaws were red and inflamed. He wore two tooth-plates. The lower was removed with difficulty, as it had not been taken out for a month. Around and beneath this plate much decomposing material had collected. The lower jaw contained three blackened teeth, of which one was loose, and four decayed stumps, one of which was also loose. He was put upon milk diet, directed to boil the plates, and go to the dentist, who reported he saw nothing requiring treatment. A week later he was able to enjoy a cutlet, and the tongue and gums were cleaner, though there was still some stomatitis. He was directed to disinfect his mouth night and morning, to use an astringent wash, and to see another dentist.

Case IV.—A woman had suffered for 15 to 20 years from intense salivation at intervals of five or six weeks, which passed off after an attack of diarrhoea. She had severe stomatitis all over her mouth, and pustules in connection with carious stumps. She wore two tooth-plates which she said were ill-fitting and caused discomfort. These plates had been unchanged for 15 to 20 years, and during that time had only been cleansed with a tooth-brush.

Case V.—A woman suffered from profound septic poisoning. The mouth was in a state of extreme ulcerative almost gangrenous stomatitis. Her temperature ranged from 105° to 106°. She had been in this condition for seven to ten days. She had had a tooth removed and the root remained. There were an abscess of the jaw and a sinus with pus lying around it on the gum. The hard palate was sloughing. The parts were scrubbed with 1 in 20 carbolic lotion, and in 48 hours the mouth looked almost normal, although the patient was almost moribund with septic pneumonia.

Case VI.—A youth suffered from inflammation of the gums after extraction of a tooth. Stomatitis set in and spread till the teeth became loose. Half the lower jaw became completely necrosed, and there was a foul gangrenous condition of the whole superior maxilla, which produced acute septicæmia, hæmorrhagic nephritis, and death.

Case VII.—A patient, who died of pernicious anemia, presented no dental history during life. *Post-mortem*: the teeth were found to be decayed in their sockets with alveolar abscesses connected with them. There was suppuration of the ethmoidal sinus on the left side.

Oral sepsis is apt to occur after the capping of carious teeth, or when the gold capping is extended as a bridge between two teeth over the adjacent gum.

Case VIII.—A patient complained of salivation due to a bridge of this kind which produced local stomatitis. On the removal of the bridge the space beneath was found to be filled with septic material, on removal of which the salivation ceased. He had a gold cap which was removed at the same time as the bridge, and replaced by another. Some weeks later salivation recurred with gingivitis round the capped tooth. On removal of the cap it was found that it covered a minute carious cavity in the neck of the tooth close to the edge of the gum.

It is important to remember that the gastritis in these cases is not due to dyspeptic trouble, but to sepsis caused by the carious teeth. Besides gastritis, local effects, such as tonsillitis, pharyngitis, otitis, abscesses, and glandular swellings in the neck, may occur in connection with diseased teeth. More remote effects are ulcerative endocarditis, meningitis, septicæmia with purpuric hæmorrhages, pyæmia, and osteomyelitis. These should be guarded against by oral antisepsis. A solution of 1 in 20 or 1 in 40 carbolic acid should be applied over each diseased tooth or stump as long as the patient delays having the tooth removed. A teaspoonful of the 1 in 20 solution to half a tumblerful of water may be used as a mouth-wash. All diseased stumps, especially when lying under a tooth-plate, should be removed. Patients should be directed to disinfect their plates by boiling. Dental apparatus which cannot be removed, and therefore cannot be rendered aseptic, should be avoided, and dentists should be warned of the risks of a septic condition of the mouth.

OPERATIVE TREATMENT OF UGLY EARS.*

BY JOHN B. ROBERTS, M.D.,

Professor of Surgery in the Philadelphia Polyclinic.

EVEN within what may be termed physiological limits, great variation exists in the size and contour of the external ear. Disfigurement occurs, however, when there is a disparity in the size of the two organs, when any other condition of asymmetry is present, or when a marked variation from the usual size, position or contour exists in one or both auricles.

This short paper is presented to the Society to direct the attention of its members to the great improvement possible in many auricular deformities. A recent French author has intimated that all medical men should be cognizant of the possibilities of modern aseptic surgery, because, even if unprepared or unwilling to undertake certain operative procedures himself, every practitioner should be at least familiar with the fact that in given conditions operative relief is possible and perhaps imperative. This same line of argument holds good in the case

* Read by title before the Medical Society of the State of Pennsylvania, Wilkes-Barre, and sent to the Record for publication.

of unsightly conditions of the ear. Many persons care little for personal appearance, and are not affected by the existence of a deformity which would make another individual morbidly sensitive and very unhappy. It seems well, therefore, for all surgeons to study with some degree of earnestness the correction of auricular defects. The subject is perhaps the more worthy of attention, as no operative treatment for the correction of these conditions is free from risk, and usually unaccompanied by confinement to bed or even absence from business pursuits.

A lacerated or incised ear should be subjected to thorough sterilization and careful suturing, so that the irregular surface may match that of its fellow. Fine silk is probably the best suture material. Wisdom in directing the course of the needle through the tissues will enable the surgeon to preserve the shape of the organ and to make a very good ear, even after considerable loss of structure.

After the removal of tumours or the occurrence of sloughing from burns, frost-bite or injury, much artistic skill is occasionally demanded in order to restore the symmetry of the two ears. It may at times be necessary to alter the shape or size of the uninjured ear, to obtain a proper correspondence with the one which has been subjected to a traumatic change. If material is needed to take the place of lost tissue, it is to be transferred from the neck or cheek, or transplanted from the hand, abdominal wall or thigh. A portion of a finger or a flap from the palm of the hand may be utilized; or a thick flap from the front of the abdomen or the thigh may be first grafted upon the hand and two or three weeks later fixed to the stump of the ear. Such a mass of muscle, fascia and skin is then modeled into proper shape by a series of minor operations. The deformity due to tearing out earrings, or to the simple piercing of the lobule for these ornaments, requires excision of the cicatrized margins of the fissure or orifice and neat suturing. The proceeding is practically the same as that to be adopted if a native of Africa or the South Seas desired relief from the disfigurement left after discarding the customary nose-ring or lip-plate.

Some deformities or distortions may be corrected by orthopaedic means, such as pads or springs, or by repeated applications of collodion. Artificial ears have been constructed of metal and other materials, and it has been suggested to imbed plates of platinum within the tissues to give rigidity to flaccid parts.

Congenital nodules in the region of the ear, sometimes called supernumerary auricles, are to be excised; unless they can be used to advantage in correcting the shape of the true auricle, in case it be misshapen. Fistulae in the same region are to be closed by dissecting out the tubular tract and neatly closing the resultant wound.

Very large ears may be successfully reduced by excising a wedge-shaped piece, or by removing a crescentic piece from the central portion of the auricle and a horizontal strip outward from the centre of the convex margin of the crescent. It is not rare for the auricles to seem exceedingly large, when the real cause of the uncomeliness is the manner in which they stand out from the side of the head. Flaring ears seem elephantine when not much above normal size. The two conditions may co-exist, the deformity then becomes very conspicuous.

Flaring ears are corrected by excising a vertical ellipse of skin and fascia from the posterior surface of the auricle and the adjacent portion of the skull, and then cutting a vertical wedge-like strip from the exposed cartilaginous structure of the organ. Sutures are then employed to sew the auricle close to the skull. Bandages or spring pads are to be used until the union is sufficiently firm to prevent tearing of the scar tissue by unexpected movements during sleep. If a condition of gigantism co-exists with the flaring, the operation for reduction of the size of the auricle may be done at the same time. A similar method is to be employed in lop ears, in which the auricle droops forward, because of imperfect development of cartilage. The displaced organ should be sewed to the scalp in such a way as to neutralize the tendency to droop. It might be possible to stiffen the auricle by inserting a thin sheet of metal in the tissues. Perhaps such an implanted metallic strip could be bent, after it had become encysted, to resemble more closely the ridges and hollows.

Absent ears, from a want of development during intra-uterine life or from accident, may be represented by celluloid, *papier-maché* or platinum constructions, properly tinted. Instead of these appliances, repeated plastic operations may be successful in making a rudimentary representation of the normal ear.

NOTE ON THE VALUE OF INOCULATION AGAINST ENTERIC FEVER.

BY COLONEL HENRY CAYLEY, F.R.C.S., I. M. S.,

*Late Officer in Charge of the Scottish National Red Cross
Hospital, South Africa.*

THE question of the value of antityphoid inoculation in producing immunity against enteric fever has attracted much attention, and its importance, especially in the case of soldiers, can hardly be over-estimated. The statistics of the army in South Africa will no doubt in due course be published, and must have great value; but, as everyone serving out there knows, the returns of patients treated in the hospital there are open to so many sources of error that any conclusions drawn from them will be very unreliable. On these points I will not now enter; but I think that the results of the inoculations of members of the staff and establishment of the Scottish National Red Cross Hospital serving in South Africa are of interest sufficient to warrant their publication.

The first section of the hospital, consisting of 61 persons—officers, nursing sisters, and establishment—left Southampton on April 21st, 1900, by steamer *Tanjore* for South Africa. During the voyage out all, except four of the 61 personnel of the hospital, were inoculated twice at an interval of about ten days. The inoculations were performed by the ship's surgeon, Dr. WORTABET, who performed the operation with the greatest care, and measured the dose of the virus for each case with exactness. The injections were all made in the flank, and were all followed in from two to eight or ten hours by marked symptoms, both local and constitutional, lasting from two to four or five days.

In many cases the symptoms were just as severe after the second as after the first inoculation. This would seem to show that it takes more than ten days before any immunity is established. Two of the seven nurses were not inoculated, because they had both suffered from enteric fever, and two of the orderlies were only inoculated once.

The material for inoculation I had received from Professor WRIGHT, at Netley, a few days before we embarked, and it was quite fresh. I may add that, out of about 300 troops on board, chiefly volunteers and militia, nearly 100 were persuaded to be inoculated.

Immediately we reached the Cape the hospital was sent up to Kroonstadt, in the Orange River Colony, and remained there as a stationary hospital till the middle of October. During this period there were always many cases of enteric under treatment in the hospital. Further, some of the medical officers and student orderlies had charge of the Kroonstadt Hotel temporary hospital, which was crowded up with enteric cases, and the nursing sisters for three weeks did duty in the military hospitals at Bloemfontein in May and June, when enteric fever was at its worst. There was not a single case of enteric among the *personnel* of this first section of the hospital.

The second section of the hospital, medical officers, nurses, and establishment—82 in all—left Southampton in May 1900. On board ship nearly all were inoculated, but many of them only once. The material for inoculation had been on board for some time, and was not so fresh as in the first instance. Of this second section, one nurse had enteric at Kroonstadt. She was the only one, out of a total of 36 nurses, who suffered from enteric, and she was the only nurse who was not inoculated, excepting the two who were protected by a previous attack of enteric. A third section of the hospital, consisting of four medical officers and 16 nurses, went out in July; they were all inoculated, and none of them had enteric.

Of the second section five orderlies had enteric fever at Kroonstadt, of whom two died. Of these five, there were two inoculated (ones) and three non-inoculated. Of the two who died, one had been once inoculated, the other had not been inoculated.

At the end of August Dr. DODGSON, who was deputed by the Director-General of the Army Medical Department to examine the results of the antityphoid inoculations, came to Kroonstadt, and was good enough to examine the blood of a number of the staff and establishment by WIDAL's test.

Of the first section who had been inoculated four months previously, he tested the blood of 23. Of these, 21 gave good reaction with dilutions ranging from 1 in 40 to 1 in 500; two gave only slight reaction—these were the two orderlies who had only been once inoculated.

Of the second section of the hospital who had been inoculated only three months previously, the blood of 22 was tested. Of these 11 gave no reaction, nine gave very slight reaction, and only two gave good reaction.

It would appear from the above that the members of the first section were much more fully protected against enteric than those of the second section. None of the

first section got enteric, though very much exposed to its influences; also the blood of all those examined showed good reaction to WIDAL's test. Among the second section there were five cases of enteric, of whom three had not been inoculated, and the other two had been only once inoculated; also the blood of 22 tested gave very slight or no reaction to WIDAL's test. It is not quite clear why the inoculations were so much more effective in the first than in the second section. Probably the freshness of the material had an influence; also I think that with the first section the dose for each individual was more exactly measured. As far as I could learn, the members of the first section suffered at the time more severely from both local and constitutional disturbances than those of the second.

The results above given are, I think, very strong evidence in favour of the protective power of the antityphoid inoculation, when the inoculations are very carefully performed, and they point to the necessity for two inoculations at a suitable interval.

During the period of five months that the hospital was stationed at Kroonstadt, there were 92 admissions for enteric fever and 11 deaths. Of the 92 cases, 15 said they had been inoculated, a few were doubtful, and about 70 had not been inoculated. Of the 11 deaths, one had been inoculated once, the others had not been inoculated.

From these figures I do not think that any conclusions or even reliable inferences can be drawn. One knows nothing as to the relative number of men inoculated or not in the different corps from which the patients came. Some of the men on admission were not in a condition to say whether they had been inoculated or otherwise. In not a few cases the patients did not know whether they had been vaccinated or inoculated against enteric, as on some of the ships the inoculations against enteric were performed on the arm. There are many other sources of error which I need not go into, but I fear that any statistics bearing on this question, derived from the hospitals in South Africa, will not be of any great value. At the same time I feel convinced, from the cases I saw in the hospital, that the attacks of enteric were, as a rule, much milder in the inoculated than in the non-inoculated, and the duration of the disease was much less.

RELATION BETWEEN CARDIO-VASCULAR AND RENAL DISEASE, WITH REFERENCE TO DIAGNOSIS AND TREATMENT.

By A. O. J. KELLY, M.D.,

Philadelphia, U.S.A.

In the early stages of granular kidney compensatory cardio-vascular symptoms—increased pulse tension, accentuation of the aortic second sound, and physical signs of hypertrophy of the left ventricle, are valuable aids in the diagnosis. When cardiac compensation fails, the diagnosis is difficult. The symptoms then resemble those of a primary cardiac disease with secondary renal affection. When dilatation of the heart occurs, it is often difficult to determine whether the cardiac mischief is primary and the renal affection secondary from congestion, or whether the case is one of granular kidney with

failure of cardio-vascular compensation. In either case the general condition of the patient is much the same: there are the general and local evidences of embarrassed circulation; the urine is diminished in quantity, of increased colour and specific gravity, and contains albumin and casts. In primary valvular disease of the heart the murmur may disappear temporarily when marked cardiac debility develops. On the other hand, in granular kidney, if the cardiac dilatation be sufficient, relative mitral incompetency may arise and a murmur may be heard.

The diagnosis may be made, in most cases, however, by bearing in mind the following facts:—In congestion of the kidney the casts are usually hyaline and the albuminuria varies from time to time with the cardiac activity. The history and the evidences of congestion of other organs are important points in favour of congestion of the kidneys. If the urine remains albuminous, in spite of the subsidence of signs of congestion in other parts of the body, if the specific gravity of the urine diminishes, and if, in addition to hyaline casts, a few epithelial casts are found, nephritis is evidently present. [We would also add that ophthalmoscopic examination is of great service. Albuminuric retinitis, if present, would show that the patient was suffering from granular kidney or a late stage of chronic parenchymatous nephritis.]

The therapeutic test is of great value in the diagnosis. If the administration of digitalis is followed by marked improvement in the condition of the patient, with disappearance of casts and albumin from the urine, the diagnosis of congested kidney is indicated. But if with cardiac improvement albumin and casts do not disappear, nephritis is indicated.

In the treatment of granular kidney no medicine is required at first. The patient should avoid excessive muscular exercise, and the action of the skin should be promoted by wearing suitable underclothing. The writer recommends milk diet for a while, especially if the patient be obliged to take to his bed. Then vegetables and fruit should be added. Meat may be taken once a day, and eggs are very suitable. Alcohol should be prohibited. Occasionally a saline purgative should be given. When the heart begins to flag, nitroglycerine and caffeine are valuable. The nitroglycerine may be given three or four times a day in tablets containing $\frac{1}{100}$ gr. each, or in minim doses of the 1 in a 100 solution. Caffein is best given in 3-gr. doses at the same time. The nitroglycerine slightly lowers the arterial tension and the caffeine acts as a mild cardiac stimulant and diuretic. Marked improvement follows the combination of these drugs. The dyspnoea, vertigo, headache, etc., disappear even in severe cases. This treatment should be continued for four to six weeks and then interrupted for a week or ten days. The treatment by nitroglycerine and caffeine is also efficacious in warding off an attack of uræmia. When there is no marked cardiac debility, digitalis should not be given. The routine administration of iron is not to be recommended, as it tends to constipate and produce headache. When marked cardiac dilatation arises and there are signs of lack of compensation, digitalis should be given in large doses. If good results are not obtained in four days, it is not likely to be of service, and strophanthus should be given instead. Strychnine also is often of service. In the late stages of the disease iodides are of little use. In the early stages, particularly if there be considerable arterio-sclerosis, they may be of service.

A MIRROR OF PRACTICE.

NOTE ON A CASE OF PROTRACTED STUPOR OR TRANCE.

By DAVID DRUMMOND, M.D.,

Senior Physician to the Royal Infirmary,
Newcastle-upon-Tyne.

D. B., a clerk, aged 26, was admitted into the Royal Infirmary, Newcastle-upon-Tyne, on March 31st, 1900, in a state usually described as lethargy, trance, or stupor.

History.—His was always more or less melancholic and reserved, and religious to the verge of fanaticism. During the previous two years he became less and less communicative and increasingly taciturn, and for twelve months prior to his admission he seldom spoke unless addressed, lost his appetite, and became thin and pale, but attended regularly to his employment until seven weeks before his admission, when he voluntarily retired into private life, and spent his time reading the Bible and taking solitary walks. A little later he declined to leave his bed, and refused food, and towards the end of March his illness culminated in a "fit" (?), when he passed into the state to be presently described.

Family History.—A neurotic family history was elicited. His grandfather died in an asylum and his brother committed suicide, whilst one brother died of phthisis during the patient's stay in the infirmary.

Condition on Admission.—He was a tall, spare, sickly, and anæmic young man. There was no history of sexual irregularities. At the time of admission to hospital it was stated by friends who brought him that he had not moved or spoken for a week. He lay motionless and took no notice of his surroundings. His eyes were open and appeared to stare in front of him with a far-away look that suggested subconscientiousness. His limbs were cold, flaccid, and unresisting. The tongue was coated and the breath foul, and nutrition much lowered. The reflexes, superficial and deep, were just perceptible, but the corneal reflex was active and the lids blinked in response to a menacing movement in front of the eyes. A very searching examination failed to discover evidence of organic disease of the lungs, heart, kidneys, etc. The contents of the bladder and rectum were passed unconsciously, and there was a tendency to a sacral bed sore.

After-history.—He slept well, closing the eyes naturally, but could be roused without difficulty. Liquid nourishment was administered through a short rubber tube attached to the spout of a feeding cup. When the fluid filled his mouth, he swallowed reflexly, and in this way four pints of milk, two pints of beef-tea and two eggs were given daily. For the rest, the treatment consisted in attending to the skin and massage with passive movements. The strongest faradic current available produced no response, and week after week he lay like a non-sentient being, moving neither arms nor legs, and apparently cut off entirely from the outer world. The pulse was fast, about 100, and the temperature varied from 97° to 98° F. At first it was supposed that he was absolutely unconscious, but the nurse in charge came to a different conclusion, for on informing him that his

brother had that day been buried, she observed that tears came into his eyes. That he was really conscious was established months later, when, on recovering his speech, he mentioned by name the clinical clerk who noted his case at an early period, and then left, to return again in a few months after improvement had set in.

About the middle of May he developed dry cough, and the temperature rose to 103° F. The left lung was found to be dull on percussion all over, and air entered imperfectly. The signs were those of pleural effusion, save that the heart was exposed to the left of the sternum. At first tuberculous disease was suspected, but soon the condition was cleared up by the nurse turning him on his face, when a quantity of foul-smelling mucous poured from the left bronchus and air entered almost immediately. It was probable that some of the food stuff had entered the trachea and blocked the left bronchus. On another occasion a large septic abscess developed in the tonsil which prevented him swallowing for several days, when rectal alimentation was practised. During this attack the urine contained a large quantity of albumen with blood and casts.

Recovery.—Notwithstanding these accidents, his condition at the end of seven months began to improve. He first moved his lips in a manner that encouraged the nurse to introduce a grape into his mouth, which he slowly sucked; then his arms and later his legs, but the power over the muscles of his limbs returned very slowly. Speech returned later, and he is now making slow, but sure, progress towards recovery.

Remarks.—The case differs somewhat from both anergic and melancholic stupor: from the first, in that consciousness and memory were not entirely in abeyance; and from the second, in that the muscles were flaccid and absolutely unresistive.

OTOMYCOSIS IN THE TROPICS:

By H. CAMPBELL HIGHT, C. M., M. D.,
Physician to the Royal Palace, Bangkok.

OTOMYCOSIS, or the growth of fungus in the external auditory meatus, is apparently a rare disease in temperate climates, if one may judge from the scanty literature on the subject. During eight years' work in Singapore and Bangkok, however, my experience has been that it is quite a common—if not the most common—disease affecting the external auditory meatus which one meets with in the tropics. The reason for this appears to be that all the conditions favourable to the growth of fungi are present—namely, heat, moisture, and the presence practically everywhere in abundance of the spores of the fungi. All my cases were in adult Europeans. Children are said to be exempt from the disease.

Symptoms.—These vary in intensity according to the severity of the case. There may be simply a sensation of blocking of the ear with slight impairment of hearing. Itching, pain, and often a considerable amount of watery discharge, is complained of, and the patient notices that his pillow has been stained during the night by a yellowish fluid which he finds exuding from one or both ears. Both ears are usually affected, but often in different degree. When an attack of acute diffuse inflammation of the meatus supervenes, as is unfortunately a frequent complication, great pain and sleeplessness follow, and often a considerable rise of temperature is noted for a few days.

Physical Appearances.—In typical first attacks the meatus is seen to be filled up with a soft wool-like substance which varies in colour, according to the type of fungus present. As I have seen it, it is usually of a pale lemon yellow or a very pale yellowish green. On passing a probe into the canal, the obstruction is found to be soft and moist and is readily removed. The walls of the canal may be found to present quite a normal appearance, but as a rule they are somewhat reddened, and the irritation may have gone as far as to have led to some desquamation of the epithelium. In cases in which the attention of the patient has been suddenly drawn to his ears by an acute attack of pain and deafness, it will be found that there are signs of extension of the catarrh to the middle ear. In chronic cases, besides the soft masses of recent fungus, impacted masses of a material like sodden newspaper are found in the meatus. These come away in large scales, or even casts of the canal, and the walls are found to have undergone thickening, so much so as in some cases to hide the tympanic membrane. Microscopical examination of the fungus reveals the presence of such common fungi as the *penicillium glaucum*, *aspergillus*, and more commonly in my experience the *massor mucedo*.

The complications noted in my cases were diffuse inflammation of the external auditory meatus, acute serous catarrh of the middle ear, chronic catarrh of the same, perforation of the membrana tympani, swelling and even abscess of the lymphatic glands at the angle of the jaw, and eczema of the meatus and pinna. The acute adenitis, the result of septic infection from the ears, was so severe in one case as to require the administration of chloroform on two separate occasions in order to open abscesses on either side of the neck.

Diagnosis is usually easy, and is at once settled by the microscope.

Prognosis.—This is a readily curable disease, but is only so if the case be taken charge of by the physician himself. To hand over the details of treatment to the patient is a plan which leads to much trouble and

disappointment. I have known of cases going on for weeks and even months when carefully attended to.

Treatment.—As much of the fungus as possible should be removed with a cotton and probe, and then the canals should be well syringed with a warm solution of bichloride of mercury (1 in 5,000). The canal is then thoroughly dried with cotton wool, so as to get rid of all water which favours the growth of the fungi, and finally it is sponged with a solution of bichloride of mercury in absolute alcohol (1 in 1,000). This gives rise to considerable pain for a moment, but it soon passes off. The alcohol is allowed to evaporate, and then the meatus is plugged with sterilised cotton-wool, which is not removed until the following day. It will then be found that many of the spores that had resisted the action of the germicide applied the previous day have germinated in the interval, and there is apparently as much fungus as before. It is not so dense, however, and is more easily removed by the same means. This process is repeated daily until no more fungus forms, then the eczema or other complication is treated in the usual way. After the fungus has ceased to grow I often insufflate a powder of boric acid 2 parts, bismuth subcitrate 1 part, and oxide of zinc 3 parts. Such a combination completes the cure not only of the oto mycosis, but also of the eczema of the meatus.

Prophylaxis consists in keeping the ear canals very clean and dry, and especially in avoiding the entrance of sea water, which, by reason of its deliquescent salts, apparently conduces more than fresh water to the growth of the fungi.

LARGE URETHRAL CALCULUS OF FOUR YEARS' STANDING : OBLITERATION OF MEATUS.

By T. M. SHAH, L. M.,

Medical Officer to the Junagadh State Hospital.

GANGADAS P., male, aged 45, admitted on 27th September 1900 with urethral calculus of irregular conical dimensions lodged in the penile portion for the last four years or more. A large fistulous opening on under the surface of penis exists, through which all urine is voided. The margins of the opening are white, fibrous, cicatricial. The stone is visible through the aperture. The meatus externus is closed, and the portion of urethra about half an inch long anterior to the seat of stone is obliterated. As the stone has increased in size and partly blocks up the fistulous opening, patient has to strain in voiding urine.

Operation under Chloroform.—The opening on the under surface of penis was enlarged by incising the urethra downwards towards scrotum and the calculus extracted.

It measured $1\frac{1}{2}$ inch in length, $\frac{3}{4}$ inch broad at its base, which was towards the meatus, the apex pointing to bladder.

Director was then forced through the obliterated portion of urethra and brought out from the meatus.

The edges of the old urethral opening were paired and then the aperture was closed by a number of horse hair sutures. Female catheter was then passed into urethra from meatus and tied in, so as to afford easy vent to urine.

28th.—Passes all urine per catheter.

30th.—Has fear : temperature 101° : passed some urine per wound and rest per catheter.

2nd October.—Catheter came away : it was reintroduced : urine passed both ways.

10th.—Greater portion of urine is passed per meatus. Patient resists introduction and retention of catheter, and left hospital half cured. Had he stayed in hospital longer and allowed retention of catheter, the abnormal opening in urethra would have entirely closed.

URETHRAL CALCULUS, PHIMOSIS, PENILE INCISION.

By T. M. SHAH, L. M.,

Medical Officer to the Junagadh State Hospital.

18th December 1900.—DHARAMSHI J., a male child, aged 3 years, was brought by his parents, complaining of painful micturition and manifest symptoms of urinary stone. On examining, after administering chloroform, the prepuce was found in a phimosed condition. It was circumcised. Stone was detected in the middle of penile portion of urethra. It could not be dislodged. Meatus was incised, but it could not be extracted through it.

Skin (after excision of phimosed prepuce) was drawn behind and the urethra was incised in its under surface just on the seat of stone which was then removed from this opening. Horse hair sutures brought the margins together, skin was drawn forward and stitched to the preputial mucous membrane as usual in cases of circumcision. The incision of meatus was also closed by sutures. Iodoform and lint were applied and retained by strap of sticking-plaster. The incision healed by first intention, urine was entirely passed through meatus, and the little patient was discharged well in a week.

Remarks.—It is very rare that penis has to be incised longitudinally for the removal of urethral calculus. As a rule, it is either forced out externally per meatus or pushed back into bladder. Penile stricture, fistula and wound of urethra are considered difficult of cure, but, as in the case under report, I have had several similar successful results after performing urethrotomy in penile region.

Indian Medical Record.

6th February 1901.

THE MEDICAL PROFESSION OF INDIA AND THE DEATH OF OUR QUEEN EMPRESS.

The Council of the Indian Medical Association held a special meeting at its Office, 50, Park Street, Calcutta, on the 26th January, and unanimously adopted the following resolution:—

RESOLVED THAT—

"The Council of the Indian Medical Association, as representing the local medical profession of the Indian Empire, do hereby express the profound sorrow of the medical profession of this Empire at the lamented death of our venerable and beloved Sovereign, the late Queen-Emress, and they respectfully offer, through H. E. the Viceroy, their humble and heart-felt condolence with His Majesty the King and Emperor, and the Royal Family, in their bereavement."

INDIAN MEDICAL ASSOCIATION.

OFFICE AND LIBRARY, 50, PARK STREET,
Calcutta, 30th January 1901.

To—The Private Secretary
to His Excellency the Viceroy.

DEAR SIR,

I beg to send you, for submission to His Excellency the Viceroy, the annexed resolution of the Council of the Indian Medical Association.

Yours faithfully,

JAMES R. WALLACE, M.D., F.R.C.S.,
Secretary, Indian Medical Association.

PRIVATE SECRETARY'S OFFICE,
GOVERNMENT HOUSE;
Calcutta, 31st January 1901.

DR. J. R. WALLACE, F.R.C.S.,
Secretary, Indian Medical Association.

DEAR SIR,

I have to acknowledge the receipt of your letter of the 30th instant, and am desired by His Excellency the Viceroy to thank you sincerely for the expressions of sympathy and condolence which you have been good enough to send to him on behalf of the Council of the Indian Medical Association upon the occasion of the lamented death of Her late Majesty the Queen-Emress; and to assure you that they will be transmitted to the proper quarter.

Yours faithfully,

W. LAWRENCE.

Private Secretary to the Viceroy.

I. M. S. MEN AS PRIVATE PRACTITIONERS. A PUBLIC SCANDAL! A STATE ENQUIRY DEMANDED.

In a recent number of this journal, which has been placed before His Excellency the Viceroy, His Honour the Lieutenant-Governor, the Director-General, I. M. S., and the Inspector-General of Civil Hospitals in Bengal, we published the regulations of Government which allow and control the system of private practice by I. M. S. men in large Indian cities. It has been sufficiently proved by those regulations that I. M. S. men may engage in private practice, only if it does not interfere with their public duties.

It is a most unpleasant task to lay charges of neglect against members of the medical profession, either collectively or individually, and we are very reluctant, under any circumstances, to do so. But in this matter of private practice by I. M. S. men, we have an exceptional and anomalous system, which finds no parallel in any other State service in India, where officers, paid for certain definite duties, are permitted to engage in private enterprise. As a matter of fact, the rules of Government positively forbid, under penalty of dismissal, any official from accepting gratuities or professional fees for services rendered in a private capacity, and they forbid such services being rendered at all.

The I. M. S., however, represents, not only in this peculiar instance, but in almost every fibre of its constitution, a huge system of anomalies. In the régime of the Honorable East India Company, medical officers in its service were allowed to engage in private practice and to receive professional fees. But surely it cannot be held that the difficult conditions under which skilled medical aid were obtainable a century ago, remain unchanged to-day, and that concessions and provisos that were justifiable then, are justifiable now. Yet it is upon this obsolete and ancient ruling that I. M. S. men claim their right and privilege to do what no other State-paid servants dare to do. We maintain that the continuance of this practice is the great stumbling-block which prevents the best men in India from entering our medical colleges, as they see nothing but starvation before them, so long as Government doctors are permitted to dominate the field of private practice in this country. The same may be said of a good class of the practitioners in Great Britain, who do not dare to come to India, so long as the door to independence is blocked by I. M. S. practitioners.

But to return to the question of the grave public scandal involved in this matter. Let us see what a certain class of I. M. S. men—say the I. M. S. "professors" of the Calcutta Medical College—have to do in the way of a single day's official duty.

We find from the Government of India Circular No. 602D. of 7th February 1898, that in addition to the work of being medical officers of the Medical College Hospital and Professors of the College, I. M. S. officers, so engaged, have also to attend gratuitously, whenever called upon to do so, day or night, a large number of gazetted and non-gazetted officers of the various services of Government in Calcutta. Thus we find this important duty of personal attendance by College Professors in Calcutta apportioned numerically as follows:—

	Gazetted.	Non-gazetted.	Total.
Professor of Anatomy ...	87	1,442	1,529
Professor of Midwifery ...	99	1,456	1,555
Professor of Surgery ...	63	1,447	1,510
Professor of Ophthalmics ...	164	1,456	1,620
Professor of Materia Medica ...	82	1,314	1,396

Putting this huge instalment of State duty as an adjunct to the work of attending 80 patients each, in the Medical College Hospital, and lecturing to a class of 200 to 400 students, not only in the regular course of lectures, but in bedside teaching, it is matter for bewilderment how these overburdened officers get through even a portion of this work.

Without attempting to lay a definite charge of neglect of duty against any medical officer engaged in the above work, we simply ask, is it possible for a man to perform this list of official duties thoroughly and efficiently, and yet to find time for private practice? When one comes to consider the arduous and onerous duties of a physician or surgeon to a large public hospital, his labors as a clinical teacher of a large class of students, his liability to be called up in to attend any serious case in his hospital, and his moral as well as his legal obligation to be accessible for such important and urgent official duty, it becomes transparently clear that such a man should, in simple and honest regard for his official duties, for which he receives a fairly handsome State salary, be within call for such work. To indulge in general and family practice renders honest execution of public duty of the kind here indicated, either absolutely impossible, or at least a very precarious possibility.

Now, when we consider the facts, what do we find disclosed? We observe that an I. M. S. professor spends an hour, or an hour and a half, at the College Hospital in the morning daily; that many urgent cases, which demand his personal attention in the hospital, are not seen by him, or they are hurried over with a promise that they will be seen the next day. That this kind of neglect happens, constantly and daily, and that many poor patients suffer for lack of timely aid, is an undoubted fact. This is no fancied picture, no stretch of imagination, no biased condemnation, but it is a sad, solemn and undeniable fact. The grievous complaints of many patients, the testimony of nurses, all go to prove the truth of this lamentable condition of affairs in the Medical College Hospital. Let a public enquiry be instituted, and the results will astound the Government and put an end to this iniquity of private practice in a single day. We simply ask for a fair and unbiased public enquiry into this whole question. It is not fair to decide the matter by the "spick-and-span" condition of things in the hospital on the occasion of a previously announced visit by the Lieutenant-Governor or by the Inspector-General of Hospitals. There must be a thorough investigation by an independent body of public men. This is the only way of getting at the truth, and of eradicating a grievous scandal, root and branch.

We are not alone in condemning private practice by I. M. S. men, nor in attaching to it a train of evils which are inseparable from such a system. We find the *Public Medical Commission of 1878*, consisting of two Indian Civilians and four I. M. S. officers, in its important report to Government, makes the following statement:—"The Committee consider that private practice has much to do with the irregularities mentioned (waste of Government stores by pilfering, and neglect of patients), inasmuch as the time of the officers concerned has been so occupied as to make them trust too much to their subordinates."

There is no escape from this straightforward condemnation, and we can only add that what was true in 1878, is magnified trebly in 1901, and it becomes the solemn duty of the Government to cause its medical servants to give a full and honest account of their stewardship.

THE I. M. S. IN STRAITS FOR CANDIDATES, THE WAY OUT OF THE DIFFICULTY.

"THE Private Medical Practitioners, for whom twenty openings now exist in the Indian Medical Service, will be engaged for one year, Government reserving to itself the power to terminate the agreement on one month's notice. The pay offered is Rs. 600 a month for those holding the Diploma of Public Health, and Rs. 500 for Associates of Home medical institutions, not so qualified. A few openings may also not improbably be found for retired Military Assistant Surgeons holding the necessary diplomas."

Such is the public announcement in the daily papers. We learn also that 29 vacancies are to be competed for in the next London competitive.

Why not have a competitive examination in India for the I. M. S.? Graduates of our Indian Universities are rightly considered as well educated as medical men in England. Why not then give them an opportunity of showing their fitness for Government service by a fair and square competitive examination? In fact, why not establish a rule that henceforth competitive examinations for the I. M. S. shall be held simultaneously in London and in Calcutta? All these dreadful forebodings about not finding suitable men in England will then cease, and men of a really better stamp—for we certainly think an Indian M. B., or M. D., is far better educated than holders of British corporate licenses—both European and Indian, will enter the I. M. S. from our Indian Colleges. The solution of the problem of finding candidates in sufficient numbers for the I. M. S. lies in opening the door of competition to Indian and Anglo-Indian graduates from local Universities.

This idea of offering temporary employment in the I. M. S., to men holding British diplomas in Public Health, is a deliberate hoax of the Director-General, I. M. S. No man in India knows better than he, that no one but a starving "ne'er-do-well," will throw up his chances of securing private practice, no matter how little it gives him, to accept the most insecure and unsuitable of posts, in which, in the present temper of the Director-General, I. M. S., no man "hailing from India" is likely to give satisfaction. We venture the suggestion that this astute official is already gloating over the opportunity of being able to point a moral from the certain failure of this insincere offer which Surgeon-General HARVEY makes to medical men in India. He means to inform the Government that "*suitable candidates are not to be found in India*," and he will then offer the further apparently reasonable counsel, "*obtain candidates in England*."

We feel it our duty therefore to warn the Government against the devices of the head of the Medical Department. Let the Government of India order a special board of examiners to assemble and test the fitness of candidates for not twenty, but a hundred appointments in the I. M. S. Let the tests, both theoretical and practical, be even more severe than the London competitive, and let the result prove the excellence of this new field for candidates for the I. M. S.

We venture to prophecy that the Government of India will get a specially good supply of medical officers for the vacancies in the I. M. S., and that this act of justice to Indian Medical Colleges will save the Government from a dilemma, which its advisers, from interested but selfish and questionable motives, are determined to represent can only be got rid of by applying for imported medical labor from England.

COMMENTS AND NEWS.

ENLARGEMENT OF THE SPLEEN IN CHILDREN (SPLENIC ANÆMIA.)

In a paper contributed by Dr. SAMUEL WEST, M.D., F.R.C.P., Assistant Physician to St. Bartholomew's Hospital and Senior Physician to the Royal Free Hospital, at the last annual meeting of the British Medical Association, the subject of enlargement of the spleen in children was discussed. We cull the essentials from the *British Medical Journal*. After dealing with the general structure of the spleen, and touching lightly upon the enlargements seen as a consequence of specific fevers, septic diseases, etc., attacked that enlargement associated with profound anæmia and known as *splenic anæmia*. Two groups were distinguished—splenic anæmia of the adults and splenic anæmia of the infant.

Splenic Anæmia of the Adult (Splenomegalia Primitiva).—

Symptoms: extreme progressive anæmia, usually without emaciation; early progressive enlargement of spleen; no enlargement of lymphatic glands; attacks of severe pain in splenic region, ending fatally sooner or later with profound anæmia, repeated hæmorrhage and extreme asthenia.

Splenic Anæmia in the Infant.—Peculiar anæmia and enlargement of the abdomen: complexion waxy, ivory-like colour, with a tinge of olive-green, which was very characteristic: abdomen hard, and enlargement of spleen often obvious to the eye: child not emaciated, but very feeble; blood shows solely changes of anæmia: little or no enlargement of lymphatic glands: most of the other symptoms were accounted for by the great anæmia: many of them are cardiac, short breath, rapid and feeble pulse, dilated heart with hæmic murmurs, palpitation and often eczema: general tendency to bleeding, recurrent epistaxis, petechiæ and later a hæmophilic condition: digestive system disturbed: diarrhoea frequent: liver enlarged in 50 per cent.: leucocytosis and often pyrexia: splenic enlargement easy to make out and not tender to palpation: urine usually unaltered: many children are rickety and some syphilitic. Histologically the enlarged spleen is found to be simple hyperplasia with slight fibrosis, and nothing more. The changes in the blood are those of simple anæmia. Nucleated red cells and megalocytes are often present in small numbers, but the eosinophile cells do not vary. If there be any increase in the number of white cells, it affects only the lymphocytes and this stands in direct relation with the fever. The affection runs a chronic course, lasting some months, but in the end many cases got quite well. In most of the cases recovering the enlarged spleen took more than twelve months to become normal: in other cases there were repeated recurrences, and in some the enlargement continues with little or no change for some two or three years. In most of the fatal cases the anæmia steadily progresses and the child dies of asthenia, and in some to intercurrent disease such as bronchitis, diarrhoea, etc. This affection commences almost invariably in infants or very young children, and when discovered for the first time in older children, has probably dated from infancy. The liability of the sexes were equal. The treatment was that of anæmia: good food, plenty of fresh air and light, cod-liver oil, hypophosphates, iron, etc.

Relation to Syphilis.—Enlargement of the spleen was almost constant in active syphilis of the child: among infants with congenital syphilis it was found in at least 50 per cent., and in a yet larger percentage among still-born syphilitic foetuses. It was only in this variety that anti-syphilitic remedies did any good.

Relation to Rickets.—Different authors varied in their figures. In about 60% of cases of rickets, enlargement of the spleen was not present. There was no relation between the degree of rickets and the size of the spleen. There was no doubt, however, that syphilis was occasionally, and rickets frequently, associated with splenic anæmia, that in neither case was the association constant, and that they could neither of them be the sole cause. The speaker then remarked on the relation which existed between the anæmia and the splenic enlargement. There were three possible alternatives: (1) The enlarged spleen may be the cause of the anæmia; (2) the anæmia may be the cause of the enlarged spleen; and (3) both the anæmia and the splenic enlargement may be joint results of some common cause. If the first was true, it had to be explained why the disease ran such an utterly different course in the adult and the infant. In the adult the changes in the spleen were referred to a peculiar cirrhosis or fibrosis of the organ which affected mainly the capsules of the Malpighian bodies and led to their atrophy. If this was the true explanation in the adult—and it was an open question—it could hardly be at the same time a sufficient explanation in the infant, in whom no pathological change of this kind was found. If neither of the earlier explanations were correct, it would seem to follow that the third explanation was the true one. It might be, as some held, that any condition of ill-health serious enough to lead to profound anæmia in infants might be associated with splenic enlargement. If this were true, it would follow that when the ill-health was cured the splenic enlargement would disappear. At the same time there were many objections to so wide a view as this, and it followed that if there were a common cause, it was not known as yet.

OYSTER FEVER.

In a communication to the *Practitioner*, Dr. JOHN WILLIAM MOORE, M.D., President of the Royal College of Physicians, Ireland, discusses the subject of fevers contracted by oyster-eating. We cull the essentials. The writer divides oyster-poisoning into three forms:—

I. Acute gastro-enteric catarrh: sudden seizure of acute gastro-intestinal disturbance: nausea, vomiting, purging, entire loss of appetite, thickly coated tongue and unquenchable thirst. After a few hours of misery the patient recovers rapidly, the poison having been eliminated. Dr. MOORE inclined to the belief that the irritant effects of the poison were in the first instance localized in the stomach, but it was possible that the gastro-enteric symptoms might be of a central nervous origin.

II. A specific continued fever, probably due to ptomaine poisoning through absorption: elimination not having been effected, poisonous albumoses were formed from the proteids during the early stage of putrefactive decomposition in the stomach and bowels, which were probably fever producers: the fever lasted from a week to a fortnight, and was accompanied by profound depression of mind and body and might terminate fatally by convulsions, coma, heart failure or peritonitis.

III. True typhoid fever, the poisonous oysters having acted in the capacity of hosts to EBERTH'S *bacillus typhosus*. Lastly, after having given specific instances of the last two varieties, Dr. MOORE describes an interesting case, in which all three phases of oyster poisoning presented themselves in succession: here the gastro-enteric irritation failed to eliminate two poisons with which the unsound oysters were charged—one of these produced an albumose or ptomaine fever, and toward the end of the third week from infection the more slowly acting poison of typhoid fever produced the

Characteristic features of that disease. The writer agrees with Dr. SIDNEY MARTIN'S conclusions that food poisoning due to bacteria may be considered under three headings: (1) Before being eaten the food may have undergone putrefactive changes, with the formation of poisonous chemical substances. The symptoms then were of rapid onset. (2) Putrefaction may not be present in the food when swallowed, but putrefactive processes in the food may subsequently occur in certain conditions of the small and large intestine and produce toxic symptoms which brought this class of cases into close relation with the first class. (3) Putrefaction may not have occurred, but the food may contain pathogenetic micro-organisms which, when swallowed, set up symptoms of poisoning. These cases, like the infective diseases, were characterised by a period of incubation, and not infrequently they produced special local lesions elsewhere than in the gastrointestinal track.

WORK AND MERIT.

Success is the goal of every man. In all the professions and trades which corrupt us, work and merit are inalienable conditions of success. Illusive schemes and combinations, excessive and sensational claims, fraudulent methods, gambling speculations and confidence, games of every description, the cleverest quack and charlatan, all fall in the long run. Temporary success may be theirs, but it is the success of the thief, and brings with it the pangs of apprehension and alarm. There is nothing established, certain, well-regulated, in such lives. They must be prepared to "move on" and begin over again continually. They live in glass houses, against which the stones of public opinion fly thick and fast.

If any man obtains a measure of permanent success in any calling, thorough investigation discloses that he has some message of good or utility to some class of men. A particular vocation may be misunderstood by many, it may be misrepresented, its aims and objects may be obscure; but if it lives and thrives, it has some elements of helpfulness to somebody.

Correspondingly, when a man fails to succeed, the cause, under any and all circumstances, is within himself. It may be a physical cause, a mental impediment, a moral weakness, but it comes from within.

Success, of course, is a relative term. It does not mean money-getting alone. Financial success is only one form of success. A man who is a good lawyer, a good doctor, a good teacher, who serves well in any department of life, is a success, and is often rewarded with a happiness which no money can buy. If, in addition to good work, he has tried to do as he would be done by, and reared his children in the same faith, he is a success as a man as well as a worker.

If the energetic and reliable man observes business principles, he will have financial success commensurate with the circumstances and conditions which govern in his particular line of endeavor.

The most successful clinician can hardly expect financial success if he keeps no books, makes no effort at punctual collections, or lives in an isolated, sparsely-settled or very healthy community.

The absence of business methods and the lack of system in their observance are the two great obstacles in the way of financial success in the profession. One type of doctor is too slack in enforcing his claims, and another makes a practice of "sticking" his wealthy patrons. No honest tradesman would follow such a policy. It would prove ruinous. Some rival would speedily take his business away from him.

So it proves in medicine. The rich man is seldom "bled" more than once. It is a mistake to presume that wealth is

so vain or proud that it enjoys protection. Men who have made money in a hard struggle against odds know the value of a dollar perfectly, and there is a rankling awareness in the sense of being swindled and imposed upon which can never be explained away.

Good service at a moderate, uniform price holds old patrons and brings new ones. "Try my doctor, or my lawyer. He will give you good advice at a reasonable figure," is the way it works. On the other hand, "Do not go to—." He will fleece you unmercifully, and his opinion is not worth any more than others."

Because a man is loose and careless in his affairs, pursuing no system with his accounts and obligations until he finds himself pressed by creditors, does not justify him in trying to make a few wealthy patrons balance his ledger.

Yet this is the argument advanced by many really able and intelligent physicians. They make bad debts and need money, so they bleed those who have it to the limit of endurance.

Such a practice is dishonest, outrageous and reflects discredit upon the profession generally. Physicians who follow it will gradually lose their practice, and find themselves in old age friendless and forsaken, railing at Providence and the world as causes of a failure for which no one is responsible but themselves.

THE TROPICAL RESIDENT IN COLD WEATHER.

THE *Medical Times and Hospital Gazette* says:—Practitioners in Britain will have many patients on their hands during the present cold spell, who have previously resided in warm climates. Hepatic derangements will constitute the majority of the conditions requiring treatment, and as they arise from the effects of cold on a tropical liver, the treatment is puzzling at times and frequently unsatisfactory and disappointing. The usual hepatic stimulants, for the most part, fail to relieve the patient, and cathartics will be found to aggravate the evils. A cold spell is the season which will make or mar the health of a person who has resided for a lengthened period in warm countries, according to the therapeutic use which the cold season is put to. Cold weather is a potent agent for good, provided the old tropical resident takes advantage of it; and the only way to obtain that advantage is out-of-door exercise. If our all-too-short, dry cold season is spent in-doors, the chief advantage of tropical residents coming to Britain for change is lost. Walking, especially when snow is on the ground, is a valuable therapeutic agent. The medical practitioner in Britain is apt to think that because a patient under his care is "upset" by the cold spell, that it is well to keep indoors—a fatal mistake; for not only will the patient not improve, but the remedial action of the cold season is missed.

When malarial sequelae, such as an enlarged spleen, are present, the weather to be welcomed is a cold, dry atmosphere; and when this is combined with a fall of snow, the old malarial patient should, and usually does, feel at his best if out-of-doors exercise is taken. A moderate enlargement of the spleen yields more readily to exercise in cold, dry air than to any other line of treatment. The cold itself may be inimical to the sexual development of the parasite, but, in addition, the stimulating effect upon the circulation, more especially of the spleen, is calculated to quicken the blood-current and excite the contractile elements of the organ, with the result that a permanent reduction of its abnormal size obtains. In advising a tropical resident, therefore, who has taken up residence in Britain for the winter, the practitioner ought to discourage his patient against the idea of running away from the cold and wintering in a mild climate.

Rather should he encourage his patient to face the cold, to take advantage of it by being out-of-doors and to avoid hepatic stimulants and derivatives. Winter, and not summer, is the time the British climate proves most beneficial to the old tropical resident, and although less pleasant in many ways, more good to health will be gained by a six months' leave being taken in winter than in summer.

In bowel-complaints, however, cold must be guarded against, and exposure carefully regulated. Patients suffering from dysentery or sprue should not go out in very cold weather, or when snow is on the ground. If the dysenteric patient feels the cold much, or the liver shows signs of congestion, bed is the only place in which the patient is safe.

The age of the patient must, however, in every instance, be taken into account. Persons over the age of 55, who markedly suffer from any form of tropical ailment, do not respond readily to the stimulus engendered by cold, and their out-of-door life must be carefully watched and regulated.

THE TRUE ARISTOCRAT.

In discussing social philosophy, the aristocratic point of view is usually mentioned only to be condemned. But the aristocratic point of view, while it may be one-sided, is not arbitrary. It is the result of natural development and experience. It is founded on the knowledge of human nature, the science of government and the weight of responsibility.

The true aristocrat is *grown*, not born or made. He is Nature's handiwork, the product of her methods and processes. Experience, suffering, effort, insight, self-victory, culture, refinement, sensibility, all these contribute to train, discipline and mould the genuine aristocrat. Small wonder that the gentleman, developed by nature in this school, should feel a certain contempt for the levelling tendencies of a Socialistic Democracy. He knows that things cannot be equalised by going down-hill, for Nature is "agin" it.

Life is simply a great hill named Difficulty, and when the aristocrat gets to the top, he naturally feels like scorning those who want to hang around the bottom and pass laws that there is no top or blow it off with dynamite. Neither does he particularly enjoy being called a heartless oppressor, because he will not take the fruits of his labors and scatter them broadcast.

It is a mistake to say that aristocrats live by privilege. No one does this but fools and knaves. The price of privilege is slavery to something or somebody. Endow a man with great estates, and if he does not live soberly and discharge his responsibilities with a reasonable measure of right and justice, he begins to degenerate in health, mind and character. The administration of his estates, or his business, as the case may be, pass into the hands of abler parties by inalienable natural laws.

Such a man may remain the nominal owner, but he is not an aristocrat, and the only privilege he enjoys is that of being a glutton, a libertine and a wine-bibber. Do we really envy men the chance to indulge their lower natures—to commit moral and physical suicide? The forces which pull us down are stronger than those which lift us up. Few of us can afford to do without the continuous spur of necessity. In few is the spirit fine enough to hear whisperings from the other world.

The aristocrat seldom makes any defence of charges made against him. He knows it is natural to the crude and undisciplined to grumble, complain, denounce. He wastes neither time nor breath on deaf ears and near-sighted eyes. He realizes that hatred and envy, misunderstanding and misrepresentation are the price he must pay for his eleva-

tion. He knows the inconstant nature of the multitude, their reckless abandonment to the feeling of the moment, the gusts of passion, the hasty acts, the brief repentance, the innumerable mistakes and errors which make up their lives. Pity for humanity in bondage to ignorance and passion, climbing the hill from which he looks down with such infinite pains and suffering, comes to soften his indignation.

All personal sense of offence fades from the mind of the true aristocrat. He stands in silent reverence and awe before the working of Nature's inexorable laws and forces.

Truly the arbitrary disposition is to be pitied. Always rushing blindly against these powerful unseen barriers and dams, rising half-stunned but unconscious what hit him, and rushing on with redoubled force and fury, only to catch it again. Such sights as these, while they call forth sympathy and compassion, make the true aristocrat impersonal in his attitude toward men. They enable him to steel his heart, to refrain from meddling interference and be willing to seem cruel in order to be kind, in affairs where governing and managerial capacity are called for.

A man is a true aristocrat only when he can say with reverence and truth: "Thy will, not mine, be done," yet work on courageously to the end.

BOGUS DOCTORS.

THE *Bengalee* says:—It is time that public attention should be drawn to a discussion which has hitherto been confined to the columns of medical journals. It is a scandal that persons should be permitted to pose before the community as qualified medical practitioners with the degree of "M.D." added to their names, when, as a matter of fact, they have never been inside a medical institution, and the degrees have been obtained by payment of money. Dr. WALLACE has obtained the names of the institutions in America which drive a profitable trade by the sale of medical degrees. Against these men who thus seek to practise deception the community must be protected; and not long ago the Lieutenant-Governor of the Punjab, in his Convocation speech, referred to this class of practitioners in terms which showed that he at any rate was alive to this growing evil. We are not in favour of legislation as a rule, for all legislation involves the imposition of new restrictions upon the liberty of the subject. But no man should be permitted to have the liberty to deceive; and, if necessary, legislation should be resorted to to put down this very objectionable form of liberty. This class of sharpers are not only a menace to the community, but they are permitted to perpetrate an injustice upon duly qualified medical practitioners. An American M. D., which has been purchased, is a very different thing from the M. D. of the Calcutta or the London University, which only men of tried ability and distinction can hope to win. But the public can make no distinction between the two. The public set the same value upon the one as upon the other. The public, therefore, are thus deceived, and that in a matter of life and death. Is it not, therefore, the bounden duty of the Government to interfere for the protection of the community? We are not lawyers, and we have not considered the question from the legal point of view. If the present law is sufficient, and the legal advisers of the Crown can tell us that it is so, then let the law be enforced against those who have been practising the deception. One or two good examples will suffice. But if the law is not sufficient, let it be amended to meet the new evil. The complaint is one of long standing, and we fear the evil is steadily growing. Dr. MAHENDRA LAL SINHA called attention to it so far back as January of last year in the *Calcutta Journal*

Current Medical Literature.

MEDICINE.

Convulsions Infantile: Etiology.

CONVULSIONS are most frequent under two years. There are two periods of frequency: under one month and between six months and two years.

The nature of the nerve-reaction resulting in a convulsion is not understood, but it is probable that instability of nervous tissues at this period of life favors this reaction.

Convulsions are frequently observed in adult life, and result from auto-intoxications and other causes.

Convulsant substances may be introduced from without or generated within the economy. (a) Substances useful to the economy, if they accumulate, become harmful—for instance, water, carbonic acid, mineral substances, the salts of biliary acids, soluble ferments, toxins not ferments in saliva, alkaloids of secretion in urine; (b) infectious agents may elaborate toxins; (c) organisms constantly present in the economy under certain circumstances may become infectious agents.

The instability of all the organs and tissues of the infant economy makes auto-intoxication common.

Convulsions occurring in rachitis and diseases associated with great nutritional disorders, all forms of gastro-intestinal disorders, and the acute infectious fevers, are most readily explained on the ground of auto-intoxication.

Convulsions resulting from marked disturbances in the respiratory and circulatory systems—as, for instance, asphyxia and hæmorrhage—are in all probability toxic.

The reflex origin of convulsions is probably not common. It should, however, be noted that when the so-called convulsive habit is established, reflex disturbance may bring on a spasm.—SANGER (*Med. Standard*).—*Cyclopedia of Prac. Med.*

Gastric Hyperæsthesia.

A. PICK understands under this term an increased sensitiveness of the gastric mucous membrane to chemical, mechanical, and thermal stimuli, or to any one of them. Thus a patient with good appetite has pain when certain articles of food or drink are taken, and this is not relieved until such food or drink has disappeared from the stomach. The more empty the stomach, the more certainly is pain produced by these articles. The stomach is most often hypersensitive to sugar, fat, and carbohydrates. There is in these cases no pain when the stomach is empty. Of thermal stimuli the stomach is more often sensitive to cold. The abnormal sensations may vary, amounting sometimes to severe pain, and even vomiting may occur. It is characteristic that fluids are as badly borne as solids, or even worse. As to chemical stimuli, sometimes acids cannot be taken, as they produce so-called heartburn or even cramp-like pain in the stomach region. Heartburn occurring a couple of hours after food is usually due to hyperchlorhydria. PICK is convinced of the reality of this acid hyperæsthesia. Sometimes along with it there are typical signs of hypersecretion. Past gastric affections, over-eating, psychical influences, mental overwork, hysteria, neurasthenia, influenza are among the causes of gastric hyperæsthesia. Pain, eructation, heartburn, and vomiting are the chief symptoms. The pain is usually diffuse and disappears when vomiting supervenes; it may be lessened by faradism. The vomiting is characteristic in so much that fluids are more often

vomited than solids. Sometimes vertigo and faintness are complained of. The diagnosis is based upon the healthy state of the gastric juice and the occurrence of periods free from symptoms. The diagnosis from gastric ulcer may be difficult. The treatment must be directed to the neurosis on which the disease depends. The feeding is important. The faradic current is useful. The treatment is largely suggestive. Medicinal agents occupy a secondary place; cocaine and menthol are the most efficient. The use of alkalies is only symptomatic treatment, and of these *magnesia usta* is the best for allaying the heartburn.—*Brit. Med. Jour.*

Epilepsy.

DR. HERMANN BEER (*Klin.-therapeut. Wochenschrift*) divides the subject as follows: A. Genuine epilepsy. Epileptic attacks without apparent cause. B. Symptomatic epilepsy. (1) Intoxicant epilepsy. Alcohol, lead, carbon dioxide, ergotin, antipyrin, arthritis (urea), nephritis (urea), intestinal sepsis. (2) Infectious epilepsy. Syphilis, cholera, variola, morbilli, sepsis. (3) Diseases of the brain. Emboli, apoplexy, tumors, multiple sclerosis, hyperæmia. (4) Reflex epilepsy. Masturbation, menstruation, pregnancy, constipation, intestinal parasites, and dilatation of the stomach, cicatrices, thrombosis in the external auditory canal or in the Eustachian tubes. (5) Traumatic epilepsy. Injuries of the head. (6) Cardiac epilepsy. (7) Physical and mental over-exertion. Irregular mode of living, worry, and depression of spirits.

Etiology of Cirrhosis of the Liver.

HYPERPLASIA of the interstitial connective tissue of the liver, with secondary contraction, results essentially to the organ through the portal vein or the hepatic artery, possibly also through the bile-duct. These influences are principally either toxic or bacterial. Of the former, some are derived from without, as alcohol, lead and highly irritating foods. Bacteria may cause cirrhosis in part directly and in part indirectly, through the poisons they generate. Other toxic substances, generated in the intestines as a result of fermentative processes, or resulting from deficient functional activity of certain organs, such as the liver, the kidneys, the skin, may also contribute to the development of hepatic cirrhosis. Sometimes no etiologic factor can be determined. As the irritating cause reaches the liver either through the portal vein or through the hepatic artery, the type of the resulting diseases will vary accordingly, with the development, on the one hand, of the lesions and symptoms of ordinary portal or atrophic cirrhosis, or on the other of biliary or hypertrophic cirrhosis. Cirrhosis of the liver may also arise in consequence of circulatory or biliary stasis or of the presence in the blood of particles of dust. The most commonly accepted cause of hepatic cirrhosis is alcoholism, but in a discussion of this subject, ROLLESTON contends that alcohol does not induce cirrhosis directly, but rather by leading to the production of sclerogenic poisons or by enabling such poisons to exert their pernicious activity on the liver.

Stuttering.

LET the patient repeat sentences, drawing the vowels and pronouncing the consonants sharply, but distinctly, maintaining the conversational tone throughout without rhythm, and avoid the singing tone. When the patient finds himself thus speaking several sentences fluently at the first sitting, the psychic stimulus is pronounced. The method can be applied to quite young subjects.—LIEBMAN.

SUMMARY.**Aural Tuberculosis.**

FERRERI, in the *Archivio Italiano di Otolgia, etc.*, writing on the diagnosis of tubercle in chronic aural suppuration, lays down the following propositions:—

(1) It is necessary, from a diagnostic as well as a therapeutic point of view, to determine the true nature of a chronic suppuration of the ear when there is a suspicion of tuberculosis.

(2) As a careful and exact means of establishing the existence of an osseous caries, an opinion from a dermatologist may be of the greatest value.

(3) As the presence of caries is not absolute testimony in favour of the existence of a specific tuberculous lesion, we ought to call in to our aid all other possible means of research.

(4) In the present uncertainty of our knowledge, the best course to follow is to make the tuberculin test, and to remove for microscopic examination the pre-mastoid lymphatic gland.

Treatment of Blisters.

ARTHUR H. WARD advocates the following: The blister is incised and the raised epidermis cut completely away with sharp scissors; no overlapping fragment beneath which microbes might develop is left. The surface is then carefully dried and painted with several layers of salicylated collodion. A circular piece of soft linen is cut rather larger than the exposed surface, and this is plastered on with more collodion, which is worked well into the meshes of the material. Several more coats of collodion are put over all. This makes a strong protection to the abraded surface, and the patient can at once walk with comfort. If a blister has been neglected and is inflamed, it should be treated with antiseptic lotions for a day or two before the method is applied.

Technique of Lumbar Puncture.

THE location for entering should fulfil three requirements: (1) Where the needle could find a ready entrance; (2) the tip should point in such a way as least likely to produce damage; (3) the fluid obtained should be rich in sediment. Any one of the three lower lumbar spaces should be chosen. At the lumbo-sacral space the fluid should be richer in sediment. The patient should assume the sitting position, but in the delirious, or comatose, there is greater difficulty in operating in this position. The upright position is generally confined to small children. An essential point to remember is that the greatest degree of flexion should be maintained; if the child is sitting, it should be bent well forward; the operator should stand on the right side of the patient and bend over the body.—L. A. CONNOR.

Nasal Empyema.

THE conclusions of COBB's article are given as follows: (1) That the whole chain of catarrhal symptoms of the nose, the nasopharynx and of the ears is due to empyema of the nasal accessory sinuses. (2) That this empyema is the result of an infective inflammation of the accessory sinuses in which the drainage is insufficient. (3) That the malformation of the posterior end of the middle turbinate, which he has described in this paper, plays an important part in the establishing of the nasal empyema which causes postnasal catarrh. (4) The chronic catarrhal inflammation of the middle ear may result from the catarrhal condition of the nasopharynx, either by extension of the disease, by continuity of tissue, by the forcible blowing of the irritating secretion into

the middle-ear cavity, or by closure of the Eustachian tube from involvement of the mucous membrane in or around its entrance. (5) That there is no evidence of chronic catarrhal inflammation of the middle ear is caused by obstruction to nasal respiration, unless the obstruction is associated with empyema of the accessory sinuses. (6) That those cases of chronic catarrhal inflammation of the middle ear which are caused or made worse by nasopharyngitis cannot be cured until the nasal empyema which causes the nasopharyngitis is first cured, and that mechanical treatment directed to the ears is only palliative and does not free the patient from the danger of an acute exacerbation of the disease. (7) That many cases of nasal empyema may heal spontaneously under favorable conditions, and the more recent the case, the more probable it is that this will occur. (8) That the accessory sinuses have a tendency to free themselves of inflammation, and that treatment should be directed to assist nature to this end. (9) That it is possible to cure practically every case of nasal empyema, and therefore every case of nasopharyngitis depending on it.

Ligation of the Abdominal Aorta.

KEEN reports a case of ligation of the abdominal aorta for aneurism in which the patient lived forty-eight days, collateral circulation having been established. The death was due, as in other cases, to cutting through the vessel by the ligature. To prevent this accident, which seems almost universal, he has devised an instrument for the compression of the aorta, which he illustrates, and which avoids the danger of pressure on the thoracic duct and requires only the opening of the abdomen and its application to the vessel. This instrument has been experimentally tried on dogs and the following are the conclusions deduced: (1) That in dogs paralysis of the hind legs follows complete obliteration of the aortic stream. (2) That the paralysed parts may regain their entire health even after forty-eight hours' compression. (3) That three and one-half hours of compression will not interfere with the complete restoration of the paralysis. (4) That at least after twenty-four hours, and possibly less, the collateral circulation may re-establish the continuity of the circulation. (5) That the aorta may be clamped in the dog for one hundred and ten hours, and yet the collateral circulation be established sufficiently to nourish the posterior extremities. (6) That the clamp can be placed on the aorta, at least in the dog, either in separate parts, or as a whole. (7) That it can be readily removed without injury to the aorta.

Topography of the Facial Nerve in its relation to Mastoid Operations.

ROBERT DWYER JOYCE, M.R.C.S., says:—(1) The facial canal lies altogether in front of the mastoid process, and a drill sent straight in from any point on the surface of the latter cannot injure the nerve.

(2) Measured from the point B, the facial canal was in 43.8 per cent. of cases more superficial than the external semi-circular canal; in the same percentage of cases this was just reversed; and in the remaining 13.4 per cent. these two structures were the same distance from the surface. Thus the external semi-circular canal cannot be taken as a guide to the depth of the facial nerve.

(3) The average distance of the facial canal from the point B is slightly less than that of the external semi-circular canal from the same point.

(4) In removing the outer wall of the attic, it should be remembered that the external semi-circular canal is almost always (81 per cent.) nearer the surface at the point C than the facial nerve; however, as it is 1.5 mm. higher than the latter, it is almost out of danger; besides, it has a thicker covering of compact bone in this situation (attic) than the nerve.

OBSTETRICS AND GYNECOLOGY.

Treatment of Abortion.

CHEEVERS summarises the history of the treatment of abortion. Thirty years ago it was all expectant; later, with the advent of antiseptics, the use of the curette was advocated for every case. Under the auspices of WINCKEL a reaction set in about ten years ago, the expectant treatment being again advocated. At the present time the question whether the routine treatment should be expectant or operative—curette or finger—is hotly debated, though all authorities are agreed that (1) the uterus must be evacuated somehow before the patient can be considered to be out of danger, and (2) with symptoms of danger active treatment must be begun. They differ, however, as to the method to be used. Some content themselves with plugging the uterus and vagina, while others would operate. The operators, again, form two schools—one would use the curette in spite of the cervix being but slightly dilated, the other requires sufficient dilatation for the introduction of the finger and exploration of the cavity. Rapid versus gradual dilatation is another disputed point. The writer then gives his own views on these questions. He believes that immediate evacuation of the uterus, generally by means of the curette, is the method of choice in all cases. It is impossible to foretell how and when any case of inevitable or incomplete abortion will terminate, and precious time may be lost by waiting. As a rule, the cervix is sufficiently dilated for the curette to be used at once; if not, a few HEGAR's dilators can be passed with very little pain, and therefore without an anæsthetic. The fragments of the ovum can be removed by the finger or the curette; by which is largely a matter of individual predilection. The curette is certainly preferable in the first weeks of pregnancy, and is always easier to sterilise than the finger. It has been urged in favour of the finger that digital exploration gives more exact information of the actual state of things than the curette. This is not the case except in the later months, when it may be difficult to decide whether the instrument is in contact with uterine or placental tissue. The finger is much more painful than the curette, and an anæsthetic is often required, necessitating, as it does, pressure on the abdominal walls with one hand, and on the perineum with the clenched fingers of the other. If the finger has been used, it is always well to finish up with the curette, which is a great prophylactic against hæmorrhage, endometritis; and, finally, a uterine douche should be given in all cases. For late hæmorrhages the curette is the best hæmostatic. If the case has been left, and the cervix closes up, it must be dilated. If the symptoms are urgent, the writer dilates rapidly under chloroform; but if there is no great haste, the dilates first with laminaria tents, and then further with HEGAR's dilators if necessary. In this way an anæsthetic is avoided, which is a great point in private practice, without considering the added risk of the chloroform. The writer therefore advocates the early use of the curette, because (1) it is simple and rapid, (2) it does not, as a rule, require an assistant. From his own experience of 500 cases he is convinced that its dangers (perforation of the uterus, etc.) have been much exaggerated, and that other methods which require either dilatation of the cervix or packing the uterine cavity are by no means free from danger.—*Brit. Med. Jour.*

Diagnosis of Ectopic Gestation before Rupture, Based on Eleven Cases.

DR. JAMES F. BALDWIN, of Columbus, Ohio, read a paper on this subject, which consisted of a brief report of six cases of tubal pregnancy which, added to five similar

cases previously reported by him, made eleven cases in which he had made a diagnosis of tubal pregnancy and had operated before the occurrence of rupture, his experience having been in direct contradiction to the dictum of LAWSON TAIT that such an early diagnosis was not possible. His argument was that in a large number of cases such an early diagnosis was entirely feasible, and would be made as a routine when the attention of intelligent general practitioners was sufficiently directed to the subject. He said that, while there were no pathognomonic symptoms of tubal pregnancy, the following points would usually be found in these cases. The patient gave a history of several years of sterility (many exceptions); she had missed a menstrual period, perhaps two of them (numerous exceptions); she had noticed some unusual pains in the pelvis, which she would probably describe as boring, gripping, or colicky in character, these pains being situated usually in the region of an ovary. She had perhaps within a few days of the time of consulting her physician had a more or less irregular hæmorrhage; perhaps had discharged pieces of membrane which she supposed indicated an abortion, and consulted her physician with the idea that such was the case, owing to the hæmorrhage and the pain and the suspicion of an existing pregnancy. Possibly, however, there had been no suspicion of a pregnancy, as the woman had accepted her sterility as incurable and had dismissed from her mind such a possibility. On making a vaginal examination, if the conditions were at all favorable, the examiner would find upon one side or the other of the uterus, or back of it, a fusiform, quite well-defined cystic tumour, about the size of a pullet's egg or a little larger. This tumour would probably be quite tender on pressure, quite symmetrical in outline, and usually distinctly pulsating. When such a tumour was found in a woman in whom there was reasonable grounds to suspect a pregnancy; when the uterus at the same time was found somewhat enlarged, and having the feel of pregnancy, but not enlarged so much as one would expect in a pregnancy of so long continuance as the history indicated, a presumptive diagnosis of tubal pregnancy was warranted, and the matter of an operation should be carefully and without delay considered. To render the early diagnosis of ectopic pregnancy possible, it was necessary for physicians to learn to suspect it, and to examine patients with that suspicion in mind. The physician who, without making any examination, told all middle-aged women who came to him complaining of irregular hæmorrhages that they were merely having the change of life, would not be likely to make an early diagnosis of cancer of the uterus, and he would probably tell patients who came to him with symptoms of ectopic pregnancy that they were merely threatened with a miscarriage. He would make no further investigations, and would hence uniformly fail to make a diagnosis. The physician, however, who, having in mind the possibility of an ectopic pregnancy, thoroughly examined all patients whose history and symptoms pointed to this condition, would in a large proportion of cases make a correct diagnosis, and by prompt intervention would achieve a signal triumph for himself and his profession.—*New York Med. Rec.*

Treatment of Uterine Polyp.

DR. SERILEAU (*La Rev. Médic.*) divides the treatment of polyp into four classes:—

1. Visible polypus with small pedicle. The tumor is seized in forceps and twisted several times, by means of which it is torn from its attachment.

2. Visible polypus with medium-sized pedicle. The cervix is dilated with laminaria tents, the tumor is twisted as before and its pedicle is cut with blunt scissors.

3. Concealed polypus. The cervix must be dilated; this permits the diagnosis to be verified. If the pedicle is of medium size, the preceding method of treatment is resorted to. If the contrary proves to be the case, it enters into the next category.

4. Polypus, concealed or visible, with large pedicle. (a) Bilateral verticle section of the cervix may prove inconvenient and insufficient, justifying (b) a median section of the uterus. This requires a transverse incision of the mucous vaginal covering on the anterior aspect of the cervix, with detachment of the peritoneum as high up as may be deemed necessary. This is the method of choice in the treatment of uterine polypi with large pedicles.

PHYSIOLOGY, PATHOLOGY, AND BACTERIOLOGY.

Internal Secretion of the Ovary.

ARTHUR W. JOHNSTON writes that retained excretions are the causes of nearly all nervous conditions, whether at the menopause or during menstrual life. There is not an iota of proof that the ovary has any other function than the manufacture of eggs. The writer believes the rule to be that if a woman's menstruation is for any reason, except pregnancy, delayed, she is very apt to have symptoms closely approximating those of the change of life. This being so, he is led to believe that the internal secretion of the ovary is a myth. The ovary, then, not having any kind of internal secretion, the troubles which accompany the menopause, both natural and artificial, are due to a faulty oxidation and excretion. One other cause of this condition is the intestinal infection that goes with nearly all these cases, and this allows the colon bacillus and its associates to contaminate the nitrogenous bodies with their ptomains before they are absorbed into the blood. Until we get rid of the old superstition of "ovarian influence" and similar terms which we have heard for so many centuries, the reproductive functions will never be thoroughly understood. As to the limits of conservative surgery: When an ovary and its accompanying tube can be left in a healthy condition, so that their functions can be easily carried out, they should be preserved, but those dangerous experiments which result in the leaving of a scrap of one ovary in one part of the abdomen and piece of a tube in another, or the transplantation of an ovary from one patient to another, should be condemned.—*Med. News*.

Study of the Vascular Mechanism of the Testis.

DIXON concludes from the study of the vascular mechanism of the testis that the organ is supplied with vasomotor nerves, and that it undergoes changes in volume passively with the blood pressure and actively as a direct result of vasomotor activity. These alterations, although well defined, are insignificant in comparison with the changes in other organs such as the kidney. The testis does not necessarily follow the vascular alterations of either the kidney or splanchnic area; thus, after injections of testicular substance, the volume of the testis and intestine expands, whilst the kidney contracts. On the other hand, after smaller injections of cantharidin, the testis and kidney contract, whilst the splanchnic area becomes dilated; in contrast to both these nicotin usually produces immediate constriction of both intestine and kidney, but induces dilation of the testis. Of the substances inducing vaso-dilation of the testis, the following are among some of the most defined: Cantharidin (late), valerian, gold (late), spermin and allied bodies, caffeine and fresh extracts of testis. The question of "internal secretion" and the significance of a dilated condition of the testis need not be discussed; but it is evident that, as in other glands, an active dilation of vessels will lead to increased activity.—*Phil. Med. Jour.*

Nature and Distribution of the New Tissue in Cirrhosis of the Liver.

THE following conclusions are reached by SIMON FLEXNER: (1) In all forms of cirrhosis the white fibrous tissue is increased. (2) Along with the increase of white fibrous tissue there is a new formation of elastic tissue. This new elastic tissue is derived from pre-existing tissue in the adventitia of blood-vessels and the hepatic capsules. (3)

Both white fibrous tissue and elastic tissue, in all forms of cirrhosis, may penetrate into the lobules. This penetration takes place along the line of capillary walls or follows the architecture of the reticulum. The chief distinctions between the histology of atrophic and hypertrophic cirrhosis depend upon the degree of extra-lobular growth and the freedom with which the lobules are invaded. In hypertrophic cirrhosis there would appear to be less interlobular growth and an earlier and finer intra-lobular growth. (4) The alterations in the reticulum, *per se*, consist, as far as can be made out at present, of hypertrophy rather than hyperplasia of the fibres. It is still uncertain whether any of the differential methods now in use suffice to distinguish between the reticulum and certain fibres derived from the white fibrous tissue of the periphery of the lobules.—*University Medical Magazine*.

Relationship between Cancer and Tuberculosis.

I. D. NAGLE gives a list of investigators who have studied the relationship of these two diseases. BURDEL declares that the appearance of cancer and tuberculosis in the same family cannot be due solely to accident, but must be the result of an intimate relation between the two diseases. CROIZER reports twenty-four cases and A. GOUIN forty-two cases of coincidence of cancer and tuberculosis. The author has in the past ten years studied the family history of more than seven hundred tuberculous patients, and found that in eighty cases the pre-existence of cancer in one or more parents was discovered. He firmly adheres to the belief expressed by CARMICHAEL in 1809, that "carcinoma and tuberculosis belong to the same family of diseases."—*Medical Examiner and Practitioner*.

Basophilic Granulations in Red Blood Corpuscles.

DR. M. LITTEK (*Ref. Fortschritte der Medizin*.) says:—In a series of more or less severe cases of anemia, which were partially of idiopathic and partially of traumatic origin, he found a large but varying number of granular erythrocytes, becoming more numerous on increase in the severity of the affection and diminishing on improvement. The granulations varied from minute dust-like particles to coarse granules, sometimes occupying the peripheral portions of the cell and at others densely filling the entire cell.

The granules occur in all those forms of red blood corpuscles which are found in anemic subjects,—in polychromatophile degeneration, in megalomicro-polikocytes, and especially in the hæmoglobin-poor, primary forms; finally, in all those forms of nucleated red cells met with in anemic blood,—in the normoblasts and megaloblasts.

Great clinical significance cannot be attached to the granulations, because they may occur in every form of anemia. They stain with all nuclear dyes of the methylene-blue group. As to their origin, he is inclined to the view that a nuclear disintegration within the nucleated red blood corpuscles is responsible for their presence.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Dampness.

THE influence of damp weather upon the sensitive man is remarkable. If there is a sore spot anywhere it hurts worse. Latent weakness of any of the organs is brought out by congestion and irregularity of function. Suppressed coughs start into activity. Neuralgic nerves speak out. Old chronic rheumatism renews its life. Corns are aggravated.

The pulse is slow, the heart weak, the blood-vessels lack tone, the muscles are flabby. The venous and lymphatic systems become engorged. The mind is languid and clouded. There is a general depression of vitality.

Damp weather favors the development of septic and typhoid states. Sick people should be protected from its influence as much as possible by building open fires in the sick room, clothing them in flannels, rubbing them, increasing the food-supply, and giving drugs of a stimulating and supporting character temporarily, such as strychnine, quinine, etc.

Education of our Daughters.

WITH the numerous avenues now open for woman's usefulness in the active world, the question of the wisest education for a girl awakens anxiety in the hearts of many mothers.

It is a difficult matter to advise as to the training of a daughter; first, because environments differ; secondly, because there can be no strictly parallel cases. One can only suggest the most practical and beneficial way of accepting the general condition of things.

Let a girl learn that which practically will be of the most benefit to her.

Health of mind demands strength and robustness of body.

Let her understand the human mechanism, and at the same time realize what is required of a woman, and how essential it is for her to be perfect in health.

In connection with this should be mental development; then add to these accomplishments, if you please, music and languages; and last, but not least, train her to be a good housekeeper, for this is of more importance than the accomplishments spoken of above.

Indeed, what is more deplorable than to allow a young girl to enter womanhood or wifehood without a practical knowledge of a household and its many requirements?

There are those who scoff at the idea of learning how to cook, considering it a homely art; but the mistress is as necessary to the home as the master.

It may be argued that so many women of to-day enter business or professional life that a practical knowledge of general housework will never be needed.

It is, however, impossible to tell how soon a woman may meet somebody who will make her believe that wifehood is her truest sphere, and these same busy women will tell you regretfully, perhaps bitterly, that the only chance they had to learn these helpful necessary household duties was when they were living with their parents.

So, mothers, learn to be charitable, broad, and noble, that your children may see in you an exemplification of the great mental and moral lessons of life.

What Constitutes A Healthy Man.

A PERFECTLY healthy man should have a strong, healthy heart: one not weak from disease or the excessive use of tobacco, alcohol, or other causes; lungs well developed and that

expand rhythmically with ample breathing space for health and a surplus for work or disease; muscles well rounded and elastic, made hard and strong by use, and carrying, like the camel's hump, reserve energy for trying journeys; nerves nature's electric wires, properly insulated and connected, bringing all the various organs of the body into one perfect system, and all under the control of a brain of just proportions, well balanced and convoluted, not soft from disease or destroyed for the need of rest; educated for the high duties it was intended to perform, not only to stand guard over and protect the health and life of the individual, but at the same time to furnish feeling and thought and pleasure for the human being. All of these organs, when properly constructed and adjusted and perfect in every detail, go to make up a healthy individual and one possessing within himself a power of resistance not easily overcome by disease-producing organisms.

Eyes of School Children.

MILLIKEN pleads for the utilization of the oral method of teaching to a larger extent than is now practiced, especially in the earlier years of school life. The greater use of the blackboard with lectures, thus avoiding close eye application, would prevent much mischief in the future life of the pupils who suffer from any degree of ocular defect. He insists on the need of the earliest possible discovery of any existing ocular weakness in school children.

Waiver of Privilege in Action for Services.

IN an action brought by a physician to recover for medical services, a counterclaim for damages was set up, the defendant and his wife testified as to his symptoms and treatment during his entire sickness, and he called as witnesses two surgeons who testified that they were called, and found him suffering from a disease other than that for which the plaintiff had been treating him, and performed two operations upon him, after which he speedily recovered. Then the plaintiff called as witnesses two physicians who had been called in consultation by the defendant's consent, but at different times, before the two surgeons mentioned were called in. The evidence of these two physicians as to their interviews with the defendant, and what they then learned, was strenuously objected to by him as privileged and inadmissible under the statute. But not so thinks Judge DUNMORE. He holds, *Hennessey vs. Kelley*, in Oneida County Court, New York, that, as applied to the facts of this case, the decisions seem to be that the defendant had the right to insist that all the physicians who attended him should remain silent as to his ailments, and as to any personal communications between him and them of a confidential nature. But when he testified in his own behalf as to the way he had been treated by the different physicians, gave conversations between him and them, uncovered the maladies from which he was suffering, both by his own testimony and that of other witnesses, including that of two of the physicians who attended him, he waived the privilege as to the remaining physicians in reference to the matters disclosed. He then uncovered and made public what before was private and confidential. It amounted to a consent on his part that all who were present and participated in the various transactions disclosed might speak freely as to what took place. When a waiver is once made, it is general, and not special, and its effect cannot be limited to a particular purpose or a particular person. After the information has once been made public, no further injury can be inflicted upon such rights and interests of the patient as the statute was intended to protect, by its repetition at another time or by another person. The rule contended for by the defendant, the court says, would leave a physician absolutely at the mercy of an unscrupulous patient.—*Jersey Amer. Med. Assoc.*

THERAPEUTICS & PHARMACOLOGY.**Action of Quinine in Pregnancy.**

CHAMBERLENT and BRUYERE (*Jour. de Méd. de Bordeaux*) state that this question is still under discussion, and that most conflicting opinions prevail. They have therefore attempted to throw light upon the subject by undertaking certain experimental and clinical studies. A short *résumé* of the result of earlier investigators is first introduced.

In 1884 RAYER made the discovery (as he believed) that quinia is an abortifacient. One year later PETITJEAN stated that a daily dose of one gram is sufficient to provoke an abortion. Numerous cases were soon reported, however, in which quinine had entirely failed to influence pregnancy, even when given in large doses. On the other hand, instances were now and then published in which the abortive action of quinine was apparently vouched for in every way.

BREQUET, the well-known expert of malaria, states in his monograph of quinia (1855) that the drug may be given without hesitation to the pregnant woman. Conflicting cases continued to be published, and in 1872 BARTHAREZ and CHIARA undertook some researches to decide the question. They experimented on healthy pregnant women, with wholly negative results. They sought to clear up the paradox by making the malarial poison the abortifacient, while quinine, by overcoming this tendency, was rather a uterine sedative than an oxytocic. On the other hand, MONTEVERDI, studying especially the oxytocic action of the drug, found that contractions of the uterus were produced thirty minutes after exhibition of the remedy.

The array of witnesses *pro* and *con* becomes too numerous for reproduction here. Authorities like TARNIER and PINARD obtained only negative results. The most recent student of the problem, TARNIER (1899), thought that quinia might have some oxytocic power in cases of inertia only.

The clinical material of the present authors is in part as follows:—

1. Woman eight months pregnant, attacked with grippe. Large doses of quinine for five consecutive days without influence on pregnancy.
2. Woman five months pregnant—severe malarial attack. Muriate of quinia hypodermically. No influence on pregnancy.
3. Another case with negative results.
4. A very nervous woman, pregnant five months. Influenza; about seven grains of quinine. During the night painful uterine contractions as if threatening abortion. Quinine not repeated. No further trouble.
5. Negative results in woman eight and a half months pregnant. Large doses of quinine given as an experiment, patient being in perfect health.

The authors naturally conclude that in the great majority of cases quinine is inert as regards the uterus; but that in a small proportion of women, who are very susceptible to the action of medicines, uterine contractions may be excited.

Antiseptic Properties of Glycerin.

CONSIDERING the frequent use of glycerin as a means for applying various medicaments, WUNSCHHEIM considered the investigation of its antiseptic properties of importance. He tested the effect of glycerin on various forms of germs, alone and in combination with various antiseptic preparations. It has no special value as an antiseptic, and if used in combination with carbolic acid and other preparations, the antiseptics must be stronger than if used with water. A concentration of 10% carbolic acid is about as effectual as a 5% solution in water; but if the glycerin be mixed with equal parts of water, the disinfectant value is equally as good as in the pure aqueous solution.

Systematic Treatment For Locomotor Ataxia.

Dose: One teaspoonful each day.

The balsam of sulphur is made by heating together 2 oz. of sulphur with 16 oz of olive oil in a stand-bath till it assumes the consistence of a thick balsam.

Correspondence.**WHAT IS A HOMŒOPATHIC PHYSICIAN.**

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—At the annual meeting of the American Institute of Homœopathy, another question of much greater and graver importance was decided, and that was the question, what is a homœopathic physician? We say of greater and graver importance, because, strange as it may appear, a large number of our schools, in their zeal to be pure HAHNEMANNIANS, would appear to ignore tacitly, if not openly, the requisite preliminary qualifications of a physician, his sole function being reduced to the mechanical comparison of the symptoms of disease with symptoms of drugs. If it were not for the law in all civilised countries to insist upon these preliminary qualifications, the HAHNEMANNIANS would abolish anatomy and physiology from their medical institutions, and with them would go physics, chemistry, and pathology as unnecessary and useless encumbrances.

If we mistake not, the pure HAHNEMANNIANS are to be found chiefly among our American confreres. And it is a matter of regret that though most of them are masters of the healing art and ornaments of the profession, not only by their special knowledge of and skill in homœopathy, but by their thorough knowledge of the whole

science of medicine, and by their general accomplishments, they should encourage such small learning amongst members of a branch of the profession, where, in addition to the special knowledge of therapeutics, there should be the highest knowledge of general medicine and of all science. It is a matter of regret, we repeat, that they should thus be the unconscious instruments of promoting what we cannot but characterise as charlatany of the worst description, because it is charlatany in homoeopathy, where no such thing ought to exist.

If the evil were confined to America, we would not have troubled ourselves about it, for in America there is enough corrective for it, and at last the most efficient corrective has been applied. Our country has been seriously affected by it. India has fallen so far from its ancient purity that it has become, *par excellence*, the land of impostures and impostors, and in no walk of life has it become so as in the medical profession, and especially in the homoeopathic branch of it. And we have the strange spectacle of America aiding and abetting the impostors by its powerful support. Nothing is easier than for the veriest ignoramus, one who cannot make an honest living in any way, to become a homoeopathic practitioner, by possessing a domestic manual and a box of medicines. And the success which such a practitioner attains in ordinary cases, especially when spoiled or given up by old school practitioners, encourages him to pursue his easy vocation with more and more persistence, and confirms him in the belief that to become a homoeopathic physician one need not go through a tedious and difficult course of regular graduation in an accredited medical institution. And in course of time he thinks so highly of his powers and abilities that he finds no difference between himself and a regularly qualified physician.

We would not object if lay, unqualified practitioners were contented with vaunting their abilities before their own patients. Strangely enough, they have actually begun a regular career of deceiving the public, and this we find they are doing by two methods. One is by sending reports of their cases and even articles to foreign journals, whose editors, somehow being made to believe that they are qualified practitioners in this country, unhesitatingly admit those articles and cases in their journals. This fact of their appearance as contributors to respectable English and American homoeopathic journals is used as a certificate to gull their ignorant countrymen into the belief of their competency and even of their superiority over the regular practitioners. We have, whenever occasion presented, sounded the note of warning to our brother-editors against admission into their journals contributions from such sources. But somehow the note does not seem to fall on the ears for which it is intended.

Yours, &c.,
NO FRAUD.

HINDU IDEAS ABOUT LEPROSY.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—Hindu treatises enumerate eighteen kinds of leprosy. They are divided into two groups. There are seven descriptions in the first group and eleven in the second. The most virulent forms are placed in the first group. Elaborate directions are given for their treatment. All these are worthy of being closely examined. With regard to the origin and causes of the disease, various theories have been enunciated. That there is a great deal in them which requires the attentive consideration of our medical men will not be denied by those who know anything of the Hindu medical system.

Most severe forms of penance are prescribed for lepers in Hindu religious books. Lepers are forbidden religious acts, and rights of inheritance are denied to them. "That Leper," say the *Shastras*, "is most vile in respect of all religious acts who is afflicted with ulcers on all his limbs, especially on temples, forehead and nose. When he dies, let his corpse be cast near a sacred river, or other holy place, or at the root of a sacred tree, let not a funeral cake, or libation of water be offered, nor his corpse be burnt, nor obsequies be celebrated. Should a man, through affection, burn the corpse of a leper who has been for six or even three months infected with the disease, that man must perform the lunar-penance of an anchorite." It was the sanious kind of leprosy which was most abominated. A man afflicted with slight leprosy may retain his right of inheritance under certain circumstances, but those who are affected with the most grievous form of the disease knew no pity from Hindu legislators. They are outcasts, and should be treated as the vilest of the vile. They are not fit objects of human mercy, and their very touch is contamination. A slow and torturing form of death is prescribed for them. By undergoing this penance their sin may be forgiven them in another world, but in this world they are beyond the reach of human compassion. All these ordinances are certainly very cruel, but they had a salutary effect. That the ancient Hindus believed that the sanious form of leprosy was contagious admits of no doubt. It was to isolate lepers, affected with the most grievous form of the malady, and to prevent affectionate relatives and friends from living with them, that such strict rules were laid down. Leprosy in India is known as *Maha vyadhi*, or the most grievous malady, and is classed among incurable diseases. It is sanious leprosy to which this term is particularly applied, and not to the other slight forms of the disease. In leading works on surgery, leprosy is not described as contagious.

The most prominent symptoms of leprosy are thus summed up in medical treatises: "Dusky red or livid tubercles of various sizes on the face, ears, and extremities; thickened or rugose state of the skin, a diminution of its sensibility, and falling-off of the hair excepting that of the scalp; hoarse nasal or lost voice; oozing; ulceration of the surface and the extreme factor." The tubercles vary in size from that of a pea to an olive. All parts, the face is particularly affected, and especially the nose and ears. Nothing certain is known regarding the cause of leprosy. Modern investigations agree with those made by the ancient Hindus: (1) That women are less liable to this malady than men; (2) that it is hereditary; (3) that its contagiousness is extremely problematical; (4) that a fish-diet is found to render every symptom worse; (5) that poor living, want of cleanliness, and exposure to cold and damp, are constant attendants on this application. Dr. COPLAND ascribes its origin to the use of semi-putrid meat and fish and of rancid oils; to insufficient vegetable food and to the contact of matter discharged from leprous sores.

The disease is as implacable a foe to the human system at the present day as it was centuries ago. Various remedies have been tried from the earliest ages, but without any effect. Garjan oil has not been found to be so efficacious as it was thought to be, and the hundred different remedies prescribed in Hindu books produce no marked effect. European medical men are as helpless in the treatment of this disease as "Hakims" and "Baidyas." The Jews had as great a horror of leprosy as the Hindus; and the expression of such a horror shows that the disease was thought by both the nation as beyond the range of human skill. Charlatans with their disinfestants afford as little relief to the sufferers as the most learned members of the medical faculties.

Yours, etc.,
L. M. S.

ASSAM OILS: A SUBSTITUTE FOR TEA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—Attention was directed some time since to the cultivation of the sunflower for its oil, but subsequent inquiries as to the chance of its proving a valuable adjunct to, or substitute for, tea are not encouraging. The oil is considered inferior to sesame or olive for table purposes; it was condemned by the Madras Railway Company as an illuminant, and dries too slowly for use with paints. Dr. J. A. VOELCKER, of the R. A. Society, says: 100 parts of whole seed yielded 45 parts of kernel and 55 of husk, while the amount of oil in the cleaned kernel was 44.07 per cent. The average yield of oil is between 16 and 28 per cent.; the yield of seed from an experimental acre was 1,778 lbs., the proportion of oil from this being 15 per cent. Sunflowers, therefore, unless chemists can discover some remunerative use for them, cannot be reckoned upon to retrieve the fortunes of Assam. On the other hand, in the energetic propagation of the homely mustard plant there may be a means of salvation. An American physician asserts that both its cake and oil are destined to play an important part in the domestic economy of the future. The oil, as is well known, is of great service in allaying skin irritation due to exposure to the sun, and when toned down with a bland oil, such as cotton, and scented with orange or other tincture, it forms the basis of many cosmetics that impart delicacy and smoothness to the complexion, and for this purpose is quite equal to, and far less harmful than, the various mixtures having arsenic as their basis. The cake ground to a coarse powder (according to the same authority) is coming into extensive use as an insecticide and disinfectant. The demand for mustard seed is increasing, as shown by the quotations, the oil now standing at Rs. 17 per maund, and it needs but energetic pushing in Europe to constitute it a formidable rival to the several "genes" for cooking, the composition of which is not always above suspicion. Assam has long been noted for the superior quality of its mustard, and as the bheel land available for its cultivation consists of thousands of acres, a large crop could be secured. Manure is unnecessary, as these waste lands are annually renovated by floods, while mere scratching with a light plough is all the cultivation needed, the heavy dews supplying sufficient moisture. The plant can be rooted up by hand, and the whole process of manufacture performed with a minimum of hand labour during the cold weather; the roots, stems, and empty pods, moreover, form a good manure for other plants, as they contain nitrogen. Here then we have a simple adjunct, unlikely to be overdone for reasons given above, and even the plain seed sent to market would pay better than tea at Rs. 20 per maund, which seems about the average planters are likely to obtain in the future. Again, probably in no part of the world does castor grow with greater luxuriance or yield more prolifically, and before the present precarious position of the tea industry became so pronounced, planters were urged to take up its cultivation for the double purpose of producing oil and cake and raising the eri silk-worm. Rape also grows to perfection as a cold weather crop on bheel lands, though an indiscriminate mixture of all the tubers of the order *Brassica* are laid under contribution for production of the seeds, so that, unless imported stock were resorted to, the true original China variety would be difficult to select. Irrespective of the oil which realises much the same in the London market, viz., 35s. per cwt., the broken-up cake is growing in demand among farmers at home, it being found that, in addition to its qualities as a manure, it attracts the wire-worm from wheat and other cereals. Peppermint grows wild all along the rainbelt at between 2000 and 5000 feet, and should be worth the attention of the Darjeeling planters. The more valuable economic oils and resins,

such as cajuput—to give it the name it is best known by—~~chalmagra~~, ~~leavon grass~~, which latter comes from a stunted tree—require from three to four years to attain full development, and thus can be recommended to the notice only of such tea companies as possess a reserve fund. But the annuals allotted to, if taken in hand by small companies on the brink of insolvency, might tide them over their difficulties for the time being, until shareholders can make up their minds how to meet the present crisis.

Yours, &c.,

OLD PLANTER.

MEDICAL TRADE NOTICES.

A NEW FORM OF TONIC TABLOID FOR INDIA.

THE particular combination employed is said to be of considerable value in cases in which an active preparation of iron, quinine, strychnine, and in the form of phosphates and hypophosphites, is indicated. The proportions of the syrups have been determined after considerable experience of their combined use; and the equivalent of 15 minims of Easton's Syrup with 15 minims of the Compound Syrup of Hypophosphites and 30 minims of Compound Syrup of Phosphate of Iron is combined in each "Tabloid" product. Each contains approximately gr. 1/85 of strychnine.

The well-known instability of the syrups, especially when subjected to the temperature of warmer climates, has seriously interfered with their effective administration. On the contrary, the active ingredients contained in "Tabloid" Three Syrups cannot undergo decomposition, thus ensuring accuracy of dosage combined with the highest efficiency. As "Tabloid" Three Syrups are sugar-coated, they are very pleasant to take, and are found to be acceptable by the most fastidious patients. Their convenience and ready portability enable patients to continue a regular course of treatment when following the ordinary round of social, professional or commercial life.

"Tabloid" Brand Three Syrups is issued in bottles containing 100 in each, by Burroughs Wellcome & Co., Snow Hill Buildings, London, E. C.

This is a most valuable addition to the already long list of convenient and pleasant preparations which Messrs. Burroughs Wellcome & Co. have given to the medical profession.

BENZO-NAPHTHOL TABLOIDS.

We have received from Burroughs Wellcome & Co., Snow Hill Buildings, London, E. C., a specimen of "Tabloid" brand Benzo-Naphthol, gr. 5, which they are introducing to the medical profession in view of the demand for an accurately dosed and therapeutically reliable preparation of this Beta-Naphthol derivative for use as an intestinal antiseptic in typhoid fever, tropical dysentery and fermentative dyspepsia.

Owing to its insolubility in water, Benzo-Naphthol has hitherto been chiefly administered suspended in mixtures or in capsules. The "Tabloid" preparation offers obvious advantages over these methods in ease of administration and acceptability to the patient.

"Tabloid" Brand Benzo-Naphthol, gr. 5, is supplied in bottles of 100.

This "Tabloid" is strongly recommended to the profession.

Government Medical Gazettes.

BOMBAY.

THE following transfers are sanctioned :—

- Hosp. Asst. Jethmal Manikrat, from Cholera duty, Hyderabad Taluka, to Civil Hosp., Hyderabad.
- Hosp. Asst. Tirithdas Khanchand, from Cholera duty, Thar and Parker Dist., to Dispy., Rato-dero.
- Hosp. Asst. Lilaram Utamchand, from Dispy., Rato-dero, to Dispy. Garhi Yassin.
- Hosp. Asst. Choithram Pessusing, from Gen. duty, Karachi, to N.-W. Ry. Hosp., Kotri.

- Hosp. Asst. Govind Rangnath, from Famine duty, to Gen. duty, Bombay.

The undermentioned are granted leave :—

- Hosp. Asst. Manaji Cuddum, Roman Catholic Orphanage School, Poona, privilege leave for three months from the 6th Nov. 1900.
- Hosp. Asst. David Joseph, Central Prison, Yerrowda, privilege leave for three months from 28th Oct. 1900.
- Hosp. Asst. Mulchand Jhamatmal, Cholera duty, Karachi Taluka, up to the 9th Sept. 1900, privilege leave for one month and half from 10th Sept. 1900.

PUNJAB.

- Hosp. Asst. Liaquat Hussain, Western Jumna Canal Dispy., Rohtak, has obtained 3 months' privilege leave, and was relieved of his duties on the 8th Jan. 1901 by Hosp. Asst. Abdul Hamid.
- On transfer from Jullundur, Hosp. Asst. Ali Ahmad was attached to the Pilgrim Camp, Mooltan, from the 8th Jan. 1901.
- Hosp. Asst. Fattah Muhammad, Ramnagar Dispy., Gujranwala Dist., has obtained 3 months' privilege leave, and was relieved of his duties on the 2nd Jan. 1901 by Hosp. Asst. Latha Ram, transferred from Kala, Jhelum Dist.
- Hosp. Asst. Kedar Nath, doing gen. duty at Rohtak, was apptd. to do special plague duty in the Gurdaspur and Shaikot Dist. from the 19th Dec. 1900.

On being relieved of the ch. of the Bahadurgarh Dispy., Rohtak Dist., Hosp. Asst. Mir Kutab Ali was transferred to the ch. of the Sirhind Canal Dispy., Sheemah, Ludhiana Dist., on the 16th Dec. 1900, relieving Hosp. Asst. Nur Mahi, who was placed on gen. duty at the Ludhiana Civil Hosp. from the 21st Dec. 1900.

Hosp. Asst. Shankar Das, at present attached to the Jhelum Canal Dispy., Ala, Gujrat Dist., having passed the English Qualification Exam. according to the test laid down in G. G. O. No. 945 of 1868, is entitled to the higher rate of pay from the 15th Dec. 1900.

Asst. Surgn. Ram Narain (II), Med. Offr., Bhakkar Sec., N.-W. Ry., has obtained three months' privilege leave, and was relieved of his duties on the 1st Jan. 1901 by Asst. Surgn. Parma Nand, transferred from Delhi.

Asst. Surgn. Umrao Raja Lal, doing gen. duty at Karnal, assumed ch. of the Karnal Dispy. on the 21st Dec. 1900, relieving Asst. Surgn. Ghulam Muhammad.

CENTRAL PROVINCES.

Civil Hosp. Asst. Muhammad Murtaza Hussain is directed to do duty under the orders of the Civil Surgn., Nagpur.

Civil Hosp. Asst. Muhammad Murtaza Hussain, doing duty under the orders of the Civil Surgn., Nagpur, is deputed on special duty at the Chhapara Cattle Fair in the Seoni Dist.

Civil Hosp. Asst. Binode Bihari Maity, doing duty under the orders of the Civil Surgn. of Hoshangabad, is granted one month's privilege leave from the date on which he is permitted to avail himself of it.

One month's privilege leave is granted to Civil Hosp. Asst. Rajoni Kanta Sahai, doing duty under the orders of the Civil Surgn. of Hoshangabad, from the date on which he is permitted to avail himself of it.

One month's privilege leave is granted to Civil Hosp. Asst. Mohendra Nath Mukerji, on gen. duty at Hoshangabad, from the date on which he is permitted to avail himself of it.

Civil Hosp. Asst. Saiyid Muhammad Mobid, attached to the Armori Branch Dispy., in the Chanda Dist., held ch. of the Famine Relief Kitchen at that stn., in addn. to his own duties, from the 2nd Oct. to the 30th Nov. 1900.

The services of Civil Hosp. Asst. Budhu Lal being no longer required for famine duty in the Civil Dept., he is directed to do gen. duty under the orders of the Civil Surgn., Hoshangabad.

Civil Hosp. Asst. Radha Kristo Das, who was on plague duty at Nagpur, was transferred to Sambalpur for famine duty in the Civil Dept.

Civil Hosp. Asst. Waman Daji Deo Sarkar, attached to the Chimur Branch Dispy., in the Chanda Dist., held ch. of the Famine Relief Kitchen at that stn., in addition to his own duties, from the 8th April to the 27th Nov. 1900.

Civil Hosp. Asst. Muhammad Amir, whose services were not required for famine duty in the Civil Dept. in the Balaghat Dist., was directed to do duty under the orders of the Civil Med. Offr., Balaghat.

Civil Hosp. Asst. Muhammad Amir, on gen. duty at Balaghat, was tempy. apptd. to the Baihar Branch Dispy. in that dist.

Two months' privilege leave was granted to Civil Hosp. Asst. Muhammad Amir, attached to the Baihar Branch Dispy., in the Balaghat Dist., from the 10th Nov. 1900.

Civil Hosp. Asst. Girdhari Parshad, attached to the Waraseoni Branch Dispy. in the Balaghat Dist., is granted three months' privilege leave from the date he is permitted to avail himself of it.

On return from the leave granted him by Deptl. order dated the 16th January 1901, Civil Hosp. Asst. Muhammad Amir is tempy. apptd. to the Waraseoni Branch Dispy., during the absence, on leave, of Girdhari Parshad.

Privilege leave for two months is granted to Civil Hosp. Asst. Dada Lakhshman Slik, on gen. duty at Raipur, from the 15th Jan. 1901, or the subsequent date on which he may be permitted to avail himself of it.

BURMA.

Hosp. Asst. Syed Mahomed Abdus Sattar relinquished ch. at the Civil Hosp., Pagan, Myingyan dist., on the 10th Dec. 1900, and assumed ch. at the Civil Hosp., Shwegyin, Toungoo dist., on the 19th Dec. 1900.

Hosp. Asst. S. Paul, on return from leave, assumed ch. at the Civil Hosp., Pagan, Myingyan dist., on the 10th Dec. 1900.

ORIGINAL ARTICLES.

AGUE, OR INTERMITTENT FEVER: ITS
ETIOLOGY AND CURE.

BY LT.-COL. MATHEW D. O'CONNELL, M.D., R.A.M.C.,
Principal Medical Officer, Peshawar District.

In malarial climates, when intermittent fevers prevail, cases are sometimes met with, in the blood of which, the bodies known as LAVEBAN'S parasites, cannot be demonstrated. It is customary to explain these cases by pointing out that if the parasite cannot be found in superficial blood, it may be found in the blood of deep-seated organs, such as the spleen, or brain, or bone-marrow, if looked for.

And if after search in such situations it still cannot be found, it is asserted that it is there all the same, even though it cannot be found.

Now this assertion is not in accordance with modern scientific methods, and I propose therefore to inquire if some more satisfactory explanation cannot be found.

After a practical experience of malarial fevers extending over 29 years, I feel convinced that these cases are due to the meteorological environment under which they occur. By this meteorological environment I mean the hot, moist, stagnant atmosphere which prevails in malarial climates. This environment may be of a higher degree of intensity in some places than in others, in some years than in others, and in some seasons of the year than in others, but its effect on those exposed to it is undoubtedly to produce an intermittent excess of water in the blood and tissues. That this intermittent excess of water in the blood and tissues affords a clear explanation of the phenomena and consequences of intermittent fever, I confidently assert. I will therefore, in the first instance, point out how this environment produces excess of water in blood, and then show how this produces an intermittent fever.

I. HOW METEOROLOGICAL ENVIRONMENT PRODUCES AN
INTERMITTENT INCREASE OF WATER IN BLOOD.

The environment under which intermittent fevers reach their highest degree of prevalence is the hot, moist, stagnant atmosphere of malarial climates.

Atmospheric Temperature.—The degree of atmospheric temperature under which they prevail is indicated in the chart. When fever is prevalent, as at Singapore, the mean atmospheric temperature is high. But that high temperature of itself is not the cause of these fevers is apparent from the temperature of Barbados shown in the same chart. There the temperature is high, but ague is not prevalent. There must be therefore some additional influence.

Atmospheric Humidity.—The degree of atmospheric humidity under which they prevail can be seen in the same chart. When ague is prevalent, as at Singapore, the mean atmospheric humidity is high. But that atmospheric humidity of itself is not the cause of these fevers is evident from the records of Great Britain shown in the same chart, where, although the humidity is high, ague is not prevalent.

Where ague is prevalent, as in Singapore, both atmospheric temperature and humidity are high. I will next proceed to make clear that exposure to such environment must produce an intermittent excess of water in the blood.

The amount of water in healthy blood is about 790 parts in 1000, but it varies within certain limits. The proportion of water depends to a great extent on the balance being maintained between the amount taken in food and drink, and the amount excreted. I take no notice of the amount formed by chemical changes within the body, as this cannot be considerable.

Excretion of water from the body takes place through the kidneys, the skin, the lungs, and intestine. Practically the amount excreted through the intestines remains constant, but the amount excreted by the kidneys and by the skin and lungs varies according to the degree of atmospheric temperature. When the atmospheric temperature is low, as in cold climates, water is excreted chiefly through the kidneys, and the excretion from the skin and lungs is small. As the atmospheric temperature rises, the quantity excreted from the kidneys diminishes, while the quantity excreted from the skin and lungs increases. When the temperature is high, water is excreted chiefly through the skin and lungs, and only in small quantity through the kidneys.

If, however, when the atmospheric temperature is high, the atmospheric humidity is also high, the excretion of water from the skin and lungs is much impeded if not altogether arrested, for it is known that atmospheric air can only take up as much aqueous vapour as will saturate it at any fixed temperature. Hence it is evident that exposure to the hot, moist, stagnant atmosphere of malarial climate must tend to produce an accumulation or increase of water in the system; and this is greatly aggravated by the increased amount of fluid taken as drink under such circumstances.

II. HOW INTERMITTENT EXCESS OF WATER IN THE BLOOD
PRODUCES AN INTERMITTENT FEVER.

The temperature of man is $F. 98.4^{\circ}$ or $37^{\circ}C.$, and this is the product of two factors—(a) the amount of heat produced within the body, and (b) the amount given off, or lost, from the body.

As regards the first, it is known that the source of heat production within the body is the metabolism or tissue change which takes place in every act of vital energy. It has long been known that this metabolism can be increased by the free internal administration of water. If experimental proof of this is required, pathologists tell us that injection of water into the blood causes a rise of temperature (PAYNE, General Pathology, p. 144). Hence there can be no doubt but that an increase of water in the blood produced by meteorological environment will in its turn produce an increase of metabolism or heat production.

But this same meteorological environment produces the increase of water in the blood by impeding evaporation of water from the skin and lungs, that this is by diminishing heat loss. If it causes increased heat

production within the body and diminished heat loss from the body, as described, the result must be increase of body temperature—fever.

Indeed this has been proved experimentally by FREY and HEILGENTHAL, who found that exposure in a Russian or hot vapour bath of F. 113° (C. 45.5°) for twenty-five minutes raised the body temperature to F. 104.3° (C. 40.3°), whilst exposure in a Turkish or hot dry air bath of F. 149° (C. 64.5°) for fifty minutes only raised the body temperature to F. 101.6° (C. 38.6°). The explanation of this is plain. In the hot dry air bath, evaporation of water from the skin and lungs, heat loss, is much increased, and keeps the body temperature down. In the hot vapour bath the evaporation from the skin and lungs is much impeded by the amount of water vapour in the air, and therefore the body temperature rises.

The temperature and humidity of air in tropical countries differ very little from those of the Russian vapour bath, and therefore this environment will as certainly, if not so rapidly, raise the temperature of those exposed to it.

It always seems to me that the weakest link in the parasitic theory of malaria is that it affords no satisfactory explanation, of that which is after all the chief clinical feature of the disease, i.e., fever. LAFERAN himself and other eminent authorities are compelled to say that the pyrogenic agency in malaria is "most likely" or "presumably" or "probably" some toxin which is liberated from the sporulating parasite shortly before or during the rigor, and which is a solvent of hæmoglobin. But the existence of any such toxin is not only not proved, it is the merest assumption. Why then attribute the pyrexia in ague to a problematical toxin born of a sporulating parasite which cannot be found in some cases, instead of to the increase of water which LIEBERMEISTER assures us is present and which PAYNE tells us will produce fever?

But although meteorological environment produces an excess of water in the blood which causes fever, as explained, it must be demonstrated that there is this excess of water in the blood of those who suffer from ague. This is probable, as the blood from such patients is described as pale, lake coloured, thin and watery (Tropical Diseases, MANSON, page 71). This probability is turned into certainty by LIEBERMEISTER, who declares that the wasting of the body in ague is sometimes concealed by the excessive amount of water contained in the blood and tissues. He says that from this cause the weight of the body may be increased as much as 10 lbs, although there may be only slight œdema of the ankles to indicate an excess of water in the blood and tissues (HILTON FAGGE, p. 48).

It is next necessary to show why this fever produced by excess of water in the blood must be of an intermittent character.

To make this evident, it is only necessary to point out that the environment which produces excess of water in the blood is of intermittent intensity, for in all climates atmospheric temperature and humidity undergo a diurnal variation. The highest temperature is reached

about 4 P.M. daily, when the humidity is, as a rule, at its lowest; and the lowest temperature is reached about 4 or 5 A.M., when the humidity is usually at its highest point. But the fall of temperature at night in the season when malarial fevers are prevalent is not sufficient to cause any considerable increase in the excretion of water from the kidneys. So that the environment which produces increase of water in the blood is more intense during a period of twelve hours, night, when, as MANSON tells us, two thirds of the attacks take place and less intense during a period of twelve hours, day. This must produce a tidal wave in the blood, in which the amount of water would reach its maximum in the early morning and minimum in the evening. It seems to me to be but an exaggeration of a process which is going on to a less extent in all climates, and which may afford an explanation of the diurnal rhythmical variation in pulse, respiration and body temperature that take place in health.

If the cause of this increase of water in the blood is thus of intermittent intensity, the increase of water will also be of an intermittent character, and so will be the increased metabolism, the fever, produced thereby.

The type of intermittent fever thus produced will depend on (a) the previous condition of the patient's blood, and (b) on the intensity of the environment. With regard to (a), it is known that in different individuals the quantity of water in the blood varies within certain limits, the average quantity being 790 parts in 1000 of blood. It will of course require exposure to the environment for some time, more or less, before the quantity of water in the blood is increased to that degree which causes fever.

Let it be assumed that the degree which causes fever is 830 parts in 1000. Then if four men whose blood contains respectively 790, 800, 810, and 820 parts of water be exposed to such environment, it is evident that the increase of water which causes fever will be most rapidly produced in the man whose blood originally contained most water or was poorest. It only requires 10 parts added to it. This accords with experience which teaches that those with the poorest or most watery blood most quickly contract ague when exposed to the environment.

It will take longer in the other men to produce the 830 parts of water, the man whose blood was in the first instance normal (790 parts) requiring the longest exposure.

Again, with regard to (b), let it be assumed that the degree of intensity of the environment to which these four men are exposed is such that it will produce an increase of water in the blood equal to 10 parts by one night's exposure. Then it is evident that the blood of the man containing originally 820 parts of water will have its water increased to that degree, 830 parts, which causes fever by one night's exposure; and although during the following twelve hours (day) critical elimination (sweat) may reduce it to the original 820 parts, still, if exposure to the environment continues, 10 parts will be added again the following night, producing the necessary 830 parts of water, increased metabolism and fever.

In this way paroxysm follows paroxysm until medical treatment be adopted, or, as will be explained hereafter, the red blood corpuscles are so much reduced that the supply of oxygen is insufficient to carry on the required oxidation: that is, the paroxysms are reproduced daily and the type of fever is *quotidian*.

At the same rate of increase, *vis.*, 10 parts each night, it will require *two nights'* exposure to produce the increase to 830 parts of water in the blood of the man containing originally only 810 parts; and after elimination (sweat) it will take *two nights* again to reproduce; that is, the fever will only be reproduced every *second* day. There will be *one* day of apyrexia. The type of intermittent fever in this case will be *tertian*.

Similarly, it will require exposure for *three nights*, at an increase of 10 parts nightly, to increase the amount of water in the blood of the man containing originally only 800 parts to the necessary 830 parts, and after elimination (sweat) it will take *three nights* to reproduce; that is, there will be *two* days of apyrexia and the type will be *quartan*.

In the blood of the man containing originally only 790 parts of water it will take still longer exposure to produce, and after elimination to reproduce, the necessary 830 parts of water. And in those with still less water in their blood, and whose excretory organs are perfect, it is conceivable that the necessary increase to 830 parts of water cannot be produced by any exposure, and in such cases we should expect immunity from the disease.

It can be seen, then, if ague is due to excess of water in the blood, produced by environment, why the type should be *quotidian* in some, *tertian* in others, and *quartan* in others; and also why those with the poorest or most watery condition of blood should most certainly and rapidly contract the disease, whilst those with naturally less water in their blood should be less liable to contract it.

In addition, if ague is due to excess of water in the blood produced by environment, it is evident why *quotidian* is the most common form in tropical climates, while *tertian* and *quartan* are the most common forms in temperate climates. For it is to be remembered that climates as regards their atmospheric temperature and humidity differ only in degree. In tropical climates, in the unhealthy season of the year, the environment (temperature and humidity) is of a higher degree of intensity, and in temperate climates lower. Hence in tropical climates the degree of hydromia that causes fever will be more quickly produced, and after elimination of water reproduced; that is, the type of ague most commonly met with in the tropics should be that with the shortest period of apyrexia, *vis.*, *quotidian*. In temperate climates, on the other hand, the environment not being of so intense degree, must of course take longer to produce, and after elimination to reproduce the degree of hydromia that cause fever; that is, the type of fever most common in temperate climates, if this theory is sound, should be that with a longer period of apyrexia, *tertian* or *quartan*. In both cases this corresponds with experience.

In unusually hot summers of cold climates the environment which causes increase of water in the blood

will also sometimes, if seldom, be found; hence the explanation of cases of intermittent fever in cold climates occasionally.

Moreover, as the amount of water in the blood depends to a great extent on the balance being maintained between the amount taken in, in food and drink, and the amount excreted, and as the amount excreted depends to a certain extent on the functional activity of certain organs—skin, kidneys, lungs, &c.—it can be seen how deranged function of such organs might of itself produce increase of water in the blood sufficient to cause fever altogether independently of external environment. By such derangement of function I would explain those anomalous cases of ague which occur in climates, seasons or localities where the hot, moist, stagnant atmosphere, the environment of ague, is not found.

Again, we know that free elimination of water from the blood in ague reduces body temperature to normal. Free sweating obviously does so. This fact in itself is strong presumptive evidence that the disease is due to excess of water in the blood, for there are many other fevers in which sweating does not produce this effect. Moreover, although sweating is the usual method of termination of a paroxysm of ague, the same result may be produced by free elimination of water from kidneys or by purging. These two latter processes, however, only reduce the amount of water in the blood, and so reduce metabolism or heat production; whilst sweating, besides reducing heat production, also increases heat loss, evaporation from the skin, and thus more quickly reduces temperature to normal.

III. HOW INCREASE OF WATER IN THE BLOOD PRODUCES ALTERATION IN BLOOD CORPUSCLES.

It cannot be said that excess of water in the blood will produce parasites, but it will produce alteration in the blood corpuscles leading to the appearance in the blood of bodies which, all admit, very closely resemble the parasites, and which others, including MANNABERG, allow are in some cases indistinguishable from them.

When there is increase of water in the blood in ague, there are present two influences which profoundly alter the blood corpuscles and lead to the appearance in the blood of the bodies referred to above which closely resemble parasites.

These influences are *increase of water and increase of body temperature*, which take place during each paroxysm. The increase of temperature may amount to as much as $F. 110^{\circ}$ ($C. 44.3^{\circ}$) in some parts of the body, such as within the portal circulation.

I will place below in parallel columns a description of the changes produced in blood corpuscles by exposure to the influence of addition of water and increase of temperature, and also a description of the appearance of malarial parasites as given by experts:—

Physiologists tell us.

1. If water be added to normal blood, the red corpuscles lose their discoid form, become spherical, swollen, and *dropical*, the hæmoglobin is washed out of them, and ultimately they disintegrate and disappear.

Experts tell us.

1. The red corpuscles attacked by the malarial parasite are usually the larger ones. They lose their disc-like shape and become spherical, swollen and *dropical*, they lose their colour and hæmoglobin, and they ultimately disappear.

2. If blood be heated, vacuoles are produced in the red corpuscles, which appear as little clear colourless shining spots that assume spherical, annular or other form. They change their form, they increase in size till they occupy half, two-thirds, or the whole of a corpuscle. They exhibit apparent amoeboid movement from contractions in the surrounding hæmoglobin, and they throw out little beaded prolongations which wave to and fro. There may be one or more vacuoles in a corpuscle.

3. The white corpuscles, which may or may not contain pigment, exhibit amoeboid movement and Brownian movement of the contained pigment. Quinine reduces the number and paralyzes the movements of the white corpuscles.

4. The result of addition of water and exposure to a slight increase of temperature is wholesale destruction of red corpuscles and production of pigment free and enclosed in spherical or various shaped bodies.

The transformation of crescent-shaped parasites and flagellation have been attributed by ROSS to variation in the density of the serum; that is, to variation in the relative amount of water in the blood. After many beautiful experiments, he, if I remember rightly, concluded that the influence which transforms crescents into spheres and produces flagellation is the abstraction of water from the serum, and that this is the influence to which crescents are exposed within the stomach of the mosquito.

MARSHALL, however, after similar experiments, concluded that the influence which produces this transformation is addition of water to the serum, and that this is the influence to which crescents are exposed within the stomach of the mosquito. Both of course cannot be right, but they agree in this, that they attribute the transformation to a variation (addition or abstraction) of water in the serum. But variation in the amount of water in the blood is precisely the pathological change which I maintain occurs in those exposed to a certain definite meteorological environment—malarial climate.

The results then of increase of water in the blood, produced by environment, are at all events, as regards the fate of the red corpuscles, the liberation of hæmoglobin, and the production of pigment, identical with those said to be produced by parasites.

The tissue chiefly destroyed by the metabolism of fever doubtless differs in different fevers, but in ague the red corpuscles of the blood are chiefly affected, leading to their extensive destruction and consequent anaemia and melanæmia.

2. Malarial parasites appear in the first instance on or in the red corpuscles as little clear, colourless shining spots of various forms, spherical, annular or other. They change their form. They increase in size until they occupy most or the whole of a corpuscle. They exhibit amoeboid movement and throw out flagella. There may be one or more parasites in each corpuscle.

3. The larger spherical pigmented parasites exhibit active amoeboid movement, and their contained pigment exhibits active swarming movement. Quinine kills the parasites and removes them from the blood.

4. The result of invasion of blood by the parasites is wholesale destruction of red corpuscles, and increase of pigment free and enclosed in spheres, crescents, &c.

Hæmolysis or destruction of red blood corpuscles is, however, a process which is always, even in health, going on within the portal circulation. The hæmoglobin there escapes from the old red corpuscles, and is in part converted into new red corpuscles, and in part into pigment. Such pigment is taken up by the hepatic cells, and forms the colouring matter of the bile and urine, &c. If it is produced in quantity exceeding the amount that the hepatic cells are capable of converting into the colouring matter of bile, urine, &c., it is obvious that it must find its way into the general circulation and into the tissues, especially of the spleen, liver, kidneys, &c., thus causing melanæmia.

Professor HUNTER, who has closely investigated this hæmolysis, tells us that it may be increased by two sets of causes—*vis.*, direct and indirect. The direct consists of agents such as water which, injected into the blood, act directly on the red corpuscles, liberating their hæmoglobin and destroying them. The indirect consists of agents which act through the medium of the splenic cells. The increased hæmolysis of disease, Professor HUNTER adds, is similar to that produced by indirect hæmolytics with two exceptions, namely, *malaria* and *hæmoglobinæmia*, which he attributes to the direct action of the parasites on the blood discs. This may indeed be so. But in cases of ague in which no parasites can be found, why attribute the increased hæmolysis to their influence, instead of to the increase of water in the blood which LIEBERMEISTER assures us is present in all cases of ague, which HUNTER asserts to be a most powerful direct hæmolytic, and which I have attempted to show in the preceding remarks is the inevitable result of exposure to the meteorological environment found in malarial climates.

During this hæmolysis, HUNTER describes the appearance of the following bodies in the blood:—

1st—*Colourless Spherules*, albuminous, and highly refractile of varying size.

2nd—*Coloured Spherules*—A red corpuscle becomes constricted at some portion, dividing into two parts, connected by a colourless portion. These are best studied by warming blood to C. 45° (F. 112°)—a temperature not much above that of blood in the portal circulation during each paroxysm of ague. The corpuscle then breaks up into a number of highly coloured spherules. This description of the disintegration of a red corpuscle by a temperature of C. 45° forcibly reminds one of the sporulation of parasites as described by plasmodists during each paroxysm of ague. In the latter, however, the colouring matter, the hæmoglobin, will have previously been washed out of them by the increase of water in the blood. Of course this resemblance of the disintegration of red corpuscles to the sporulation of parasites becomes more interesting, as it takes place within the portal circulation, the very situation where plasmodists tell us the parasites may be found when they cannot be found in peripheral blood.

3rd—*Stromata* or decolorized blood corpuscles, which are best studied by the injection of water into the blood.

Now, if these bodies, colourless spherules, coloured spherules which break up into a number of highly

coloured bodies, and stromata, &c., are produced within the portal circulation in health, and if, as HUNTER tells us, their production is increased by heat $C. 45^{\circ}$ ($F. 112^{\circ}$) and injection of water into the blood, it is obvious that their production must be increased during each paroxysm of ague when the temperature of the blood in the portal circulation is nearly as high, and when there is increase of water in the blood.

MANSON, a high authority on malaria, tells us in his *Tropical Diseases*, page 70, that the destruction of red blood corpuscles in malarial disease is greatly in excess of anything which can be accounted for by the number of corpuscles attacked and consumed by parasites. The number of parasites found in the blood might account for a destruction of one per cent. or even five per cent., but not for a 20 per cent. destruction, which is not uncommon even after a single paroxysm of ague.

But if ague is due to excess of water in the blood, as I maintain, it would not only account for a destruction of 20 per cent. of the corpuscles, but, when extreme in degree, it would explain the almost total destruction of blood corpuscles, such as is found in hæmoglobinuric fever. Increase of water in the blood must affect every corpuscle in it. The greater the increase of water, the greater will be the destruction of blood corpuscles. Hence it is that I consider hæmoglobinuric fever but an extreme degree of the pathological condition found in ague.

In the first place hæmoglobinuric fever occurs in those countries and climates where may be found at times an extreme degree of the meteorological environment which causes an increase of water in the blood. In the next place the parasitic origin of hæmoglobinuric fever is not established. MANSON, at the meeting of the British Medical Association, said that the opinion that this disease is of parasitic origin is based more on considerations of probability than on logical deduction from demonstrated fact (*British Medical Journal*, 1st September 1899, page 558). And, lastly, increase of water in the blood, as has been pointed out, causes fever, anæmia and melanæmia. When it reaches an extreme degree, it must also obviously produce hæmoglobinuræa; for, as has long been known, it washes the hæmoglobin out of the red corpuscles in the plasma. When this change is extreme, then the result must be hæmoglobinuræa.

As previously pointed out, the hæmoglobin is liberated from the corpuscles in the portal circulation in health, and formed, in part, into pigment, which is converted by the hepatic cells into the colouring matter of bile, urine, &c. As HUNTER tells us, water injected into the blood increases the liberation of hæmoglobin, and therefore increases the formation and flow of bile. If excessive, this leads to bilious symptoms, vomiting and diarrhoea. When the amount of hæmoglobin liberated is very great, greater than can be disposed of by the hepatic and other cells, then it is excreted by the kidneys giving rise to hæmoglobinuræa.

This it seems absolutely certain, from a consideration of ascertained facts, that increase of water in the blood, produced by exposure to tropical climates, will cause increased metabolism fever, liberation of hæmoglobin from

the red corpuscles, anæmia, melanæmia, bilious diarrhoea and vomiting, and hæmoglobinuræa.

Enlargement of the Spleen.—All know that the spleen becomes larger during each paroxysm of ague, and returns in the intervals at first to its normal size. Eventually, however, if the paroxysms are often repeated, it becomes permanently enlarged. That the intermittent enlargement of the spleen is one of the effects of the intermittent increase of water in, that is of volume of, the blood, produced by environment, is conceivable. It is known that, like blood destruction (hæmolytic), periodical enlargement of the organ goes on even in health, but slight in degree. That the intermittent enlargement of the spleen which takes place in ague will, if repeated often enough, end in permanent enlargement of the organ is certain; for it is known that hypertrophy of an organ is more likely to occur from transitory but repeated hyperæmia than from hyperæmia continued for some time.

Prevention of Ague.—*Drainage of the soil* in paludal districts eradicates, or at all events much reduces, the prevalence of ague. The most obvious effect of drainage of the soil is that it dries the superincumbent atmosphere. Drainage therefore reduces, or removes, one factor—atmospheric humidity—of the environment that produces increase of water in the blood.

In low-lying, flat and swampy places fevers often disappear when the swamp becomes completely flooded from heavy rain or otherwise; and this is only to be expected when it is remembered that evaporation is greater from a swamp than from an equal surface of water. Flooding therefore reduces the amount of vapour given off to the atmosphere, and this reduces the humidity of the atmosphere.

Residence in well-raised, well-built houses serves as a protection against malaria, and it is plain that the atmosphere in such is much drier than in the open, especially at night. Not only this, but in huts, tents, or perhaps within mosquito nets, the atmosphere is drier than it would be in the open.

Treatment of Ague.—All effective treatment of ague reduces the amount of water in the blood. Diaphoretics, diuretics and purgatives obviously do so. That quinine is both diuretic and diaphoretic will scarcely be denied by any one who has taken it in large doses.

When the chronic stage of ague is reached, what is so beneficial as a course of Turkish or dry air baths and massage when available, and what is more calculated to remove water from the blood?

With regard to my view that the atmospheric environment found in tropical climates produces increase of water in the blood, increased hæmolytic and melanæmia, and therefore increased work for the hepatic cells, may it not also explain the greater liability of new arrivals in such climates to hepatic disease, as well the characteristic darkness of the skin of the indigenous races?

What I have written may be briefly summarised as follows:—

1st.—The meteorological environment found in malarial climates produces an intermittent increase of water in the blood of those exposed to it.

2nd.—Intermittent increase of water in the blood by increasing metabolism, heat production, causes fever.

3rd.—There is known to be increase of water in the blood in ague.

4th.—Elimination of water (sweat) from the blood in ague reduces temperature to normal.

5th.—Increase of water in the blood causes extensive destruction of red corpuscles, anæmia and melanæmia.

6th.—An extreme degree of such increase of water in the blood produces all the symptoms and signs of hæmoglobinuric fever.

7th.—Removal from the environment that produces increase of water in the blood cures ague.

From these facts, I think it may be safely concluded that ague and hæmoglobinuric fever are due to increase of water in the blood produced by environment.

THE CLINICAL PICTURE OF EPIDEMIC INFLUENZA.

By GLENTWORTH R. BUTLER, M.D.,

Attending Physician to the Methodist Episcopal and Brooklyn Hospitals; Consulting Physician to the Bushwick Central Hospital, Brooklyn, N. Y.

THE subject of this paper, although well worn, is not devoid of interest. The clinical picture of epidemic influenza is a composite—several panels set into a single frame. The name of the disease is itself a misnomer, a considerable proportion of cases exhibiting no catarrhal symptoms referable to the upper air-passages. This fact is in consonance with the modern conception that many of the specific infections may affect the organism as a whole, without necessarily giving rise to certain special and localised lesions, the presence of which was formerly considered a pre-requisite to the existence of the disease. Thus the finding of intestinal ulceration is not essential to the *post-mortem* diagnosis of typhoid fever, for in this disease there may be a generalised typhoid septicæmia, or the brunt of the attack may be borne by the lungs (pneumotyphoid) or the kidneys (nephrotyphoid). So, also, scarlet fever may kill without an eruption; or in lobar pneumonia the systemic infection may be so intense and overwhelming that death takes place in the stage of engorgement and beginning consolidation, or, in the same disease, the general septicæmia dwarf into insignificance the pulmonary localization, although life has been sufficiently prolonged to allow ample time for the development of the latter.

As with these, so with influenza. The incidence of the toxin of the influenza bacillus (PFEIFFER'S) may fall sometimes upon one, sometimes upon another, organ or system; or after expending its force upon one set may subsequently involve others; or may manifest itself as a general acute toxæmia. The symptomatology of the disease is therefore extraordinarily diverse, and for this reason the disease has superseded malaria as a diagnostic scapegoat with the careless and easily satisfied examiner.

In general, after an incubation of from one to four days, the disease sets in abruptly with chilliness or, in

some instances, with a severe rigor. In women, recurring syncope is not uncommon. Fever is almost always present, but is extremely variable, ranging from 100° to 105°F., and continuing with irregular remissions for from one to ten days. Recurring chills with high intermittent fever, closely simulating malarial fever of the same type, are not very uncommon; but a blood-examination shows the absence of the plasmodium.

There is, in almost all cases, severe headache and general aching, with a degree of weakness and prostration which, except in the presence of severe complications, is out of all proportion to the apparent cause. Delirium is not uncommon, especially in women, children and neurotic men.

The general symptoms just described are manifested in varying degrees in all cases. Depending upon the special localization of the infection, certain varieties of the disease are recognized.

The early symptoms of the *respiratory form*, which is perhaps the most common, are those of a severe coryza, followed usually by pharyngitis, laryngotracheitis and bronchitis. Very commonly a careful examination will reveal a slight, patchy pneumonia with scanty physical signs. The cough is apt to be violent and paroxysmal. The occasional extraordinary persistence of the influenzal cough is one of the remarkable features of the disease, and it may prove one of the most difficult problems of the therapist. Morphine or narcotism, in addition to a long list of antispasmodics, sprays, and inhalations, has failed to arrest it, even temporarily, in fortunately rare cases. In other instances the general aching and extreme weakness may be the only characteristics which prove an apparently ordinary coryza to be a true influenza.

The *nervous form* of influenza is almost as common as the respiratory form. The fever is slight, but there is atrocious headache, severe pain in the back and limbs, and marked prostration. These may be, and often are, the only symptoms; but in a certain proportion of cases coryza and cough supervene in the course of two or three days. This is a sufficiently frequent occurrence to require a word of forewarning to the patient.

When the spite of the poison is vented upon the stomach and intestines—the *gastro-intestinal form*—there are nausea, vomiting, abdominal pain, and a profuse watery or serous diarrhoea. With these symptoms there is extreme prostration, amounting at times to actual collapse. Such cases are luckily not common, but the possibility of their occurrence during an epidemic of the disease should be borne in mind. I recall an experience of a few winters past in which seven members of one family fell ill, one following the other at intervals of two days, with the regularity of the scholastic row of bricks, three with the nervous form, three with the respiratory form, and one with the gastro-intestinal form of the disease—facts which permitted an easy diagnosis in the last case.

Still more rare is the *typhoid or febrile variety* of this disease. The fever is of the continued type, with delirium, dry, brown tongue, tympanites and other

evidences of the typhoid status. The recurring chills and intermittent type of fever which characterise a certain proportion of cases have already been mentioned.

The portrayal of the disease is incomplete without a reference to its complications, sequelæ, and occasional symptoms.

Bronchopneumonia is the most common of the respiratory complications; the lobar form less so. Pleurisy is not uncommon, but seldom terminates in empyema. Abscess and gangrene of the lung are rare sequelæ. Edema of the lungs may occur, almost invariably as a sequence of pneumonia. Enlargement of the bronchial glands, of which the physical diagnosis is very uncertain, is, perhaps, rather frequent. Indeed the persistent cough of influenza has been attributed with some show of probability to irritative pressure upon the laryngeal nerves by the swollen lymphnodes.

Certain symptoms or sequelæ belonging to the organs of circulation are very common. The pulse often remains unduly frequent or quickens disproportionately after exertion for long periods subsequent to the attack. Two instances of paroxysmal tachycardia have been noted in personal experience as a consequence of influenza. On the other hand, bradycardia may follow. An irregular pulse is not uncommon. Several cases of the so-called influenzal angina pectoris have been of much practical and prognostic interest. Women, usually but not necessarily of the neurotic type, appear to be the principal sufferers. The pain may be very severe, precipitated especially by mental emotion, less often by physical exertion, and the severest attacks may occur at night. The heart action is usually weak and often irregular. All the cases seen, in two of which a diagnosis of true stenocardia had been made by good observers, have recovered in periods varying from six to eighteen months. In all of these the patients were under forty years of age, and there were no physical signs of arterial degeneration. A weak, often dilated heart, without anginal symptoms, is by no means infrequent. Inflammation of the pericardium and endocardium may occur; so also may phlebitis and thrombosis of different vessels.

The nervous system is affected to some extent in all cases. Thus depression of spirits is extremely common, sometimes developing into an actual melancholia; and a persistent insomnia may follow an attack. Active delirium has been noted, and one case of acute mania, which recovered under sanitarium treatment, occurred last winter as a sequel of a grippal bronchopneumonia. Neuralgias are common; migraine less so. Inflammatory diseases of the nervous system may be initiated. Occasionally one sees cases presenting the symptom-group of cerebral meningitis, these symptoms persisting for two or three days and then vanishing. In two instances death occurred after violent meningeal symptoms, and the autopsies showed intense cerebral hyperemia, evidently the beginning of an acute encephalitis. In such cases recovery may occur with a resulting hemiplegia or monoplegia; the formation of an abscess of the brain is rare. Much more frequently encountered is some form of neuritis.

Neurasthenia of a light grade is perhaps the proper term to apply to the prolonged weakness of convalescence from this disease; but it is astonishing to realize the frequency with which a severe and protracted neurasthenia can be traced directly to an attack of influenza—an attack which, at the time of its occurrence, did not seem to be of special intensity. In these cases one cannot help acknowledging a special predilection of the influenza toxin for the nervous system, even when allowance is made for the natural inclination to attribute a condition to the most obvious, although not necessarily the most efficient, cause.

The spleen may enlarge acutely as in other acute specific infections. Catarrhal jaundice is a sequel of which several instances have been observed, due usually to a gastroduodenitis arising from the action of the poison upon the mucosa of this part of the intestinal tract although the jaundice may be purely of the toxæmic form.

Acute nephritis is not rare; hæmaturia and acute congestion without a true nephritis may occur. Conjunctivitis, as a part of a coryza, is frequent, iritis uncommon, and optic neuritis rare. A rather common complication is a suppurative inflammation of the middle ear, followed in an unusual proportion of cases, especially during the winter of 1899-1900, by mastoiditis. In one case the symptoms were so violent and threatening that operation was imperative at the end of forty-eight hours from its inception, and the whole mastoid process was found to be infiltrated with pus. The fever, which at the time of operation was 105.6° F., subsided very gradually, not reaching the normal until two weeks after the surgical interference. Vertigo, sometimes very persistent, and occasionally due to labyrinthine disease, is not infrequently observed. Herpes labialis is very common. Sometime a diffuse erythema, and possibly purpuric spots, are witnessed.

With reference to the diagnosis, it is desirable that in doubtful or suspected sporadic cases a bacteriological examination of the bronchial or nasal secretions should be made in order to find PFEIFFER'S bacillus, which, if present, will declare the disease influenza. This examination is not easy, and is reliable only when made by an expert. During the existence of an epidemic there is usually no difficulty in making a diagnosis, nor in a sporadic case if the symptoms range themselves under the head of one of the recognized types. The cardinal symptom is the excessive and disproportionate weakness. The disease may require differentiation from the following:—

1. *Typhoid Fever*.—Influenza begins suddenly and lacks the regular temperature curve, rose spots, and positive WIDAL reaction of typhoid fever.

2. *Cerebrospinal Meningitis*.—In certain cases of influenza the sudden onset, headache, backache, delirium, and muscular stiffness may afford a clinical picture exactly like that of cerebrospinal meningitis, and the differential diagnosis must depend upon the bacteriological examination; in the one case for the PFEIFFER bacillus, in the other for the meningococcus.

3. *Bronchopneumonia*.—If the question arises as to whether a given case of bronchopneumonia is of influenza

origin, a rather peculiar and anomalous combination of physical signs may answer the question in the affirmative, viz., varying degrees of dulness over both chests posteriorly, with weak respiratory murmur, impaired transmission of voice sounds, and a shower of fine and subcrepitant râles at the end of a deep inspiration, heard in scattered areas or patches, especially at the bases. The combination is probably indicative of a mixture of bronchopneumonic spots and collapsed lobules.

As to prognosis, recovery occurs in the large majority of cases. The mortality varies from $\frac{1}{2}$ to 2 per cent., and is generally due to a complicating severe pneumonia, especially when affecting the very young or the aged.

VAGINAL HYSTERECTOMY FOR CANCER: ITS LIMITATIONS AND RESULTS.

By Mrs. MARY ANN DACOMB SCHARLIEB, M.D., M.S., LOND.,
Senior Surgeon to the New Hospital for Women, London.

It might be thought that the time had gone by in which it was necessary or desirable to report cases of vaginal hysterectomy, to mention the limitations of the operation, to describe methods, and to register results, both immediate and remote. It might be supposed that such efforts were simple anachronisms, were it not for the startling pronouncement of a distinguished surgeon that he is of opinion that vaginal hysterectomy for malignant disease is a most unsatisfactory operation, carrying a heavy percentage of deaths as its immediate result, and as its remote result recurrence usually within three months. If surgeons of position and experience write and teach thus, it is the duty of every surgeon to put on record the exact results of the operation in his or her hands.

The following analysis is based on 46 consecutive cases of vaginal hysterectomy, of which 35 were for malignant disease, eight for fibroids, two for procidentia, and one for suppurating involving the uterus and left broad ligament in a woman in whom both sets of appendages had been removed a year before for gonorrhoeal pyosalpinx. The 11 non-malignant cases recovered, and are in satisfactory health at the present time.

The diagnosis of malignancy in the present set of 35 cases was based on the clinical history, signs, and symptoms verified by a microscopic examination conducted by a competent pathologist. In nine of the malignant cases the cervix appeared to be healthy, the disease affecting the body only of the uterus. This proportion, rather more than 25 per cent., is in excess of the usually accepted ratio, but no doubt as the importance of dilatation and curettage in cases of menorrhagia and metrorrhagia is increasingly realised, the teaching on this subject will be modified. Two of the nine cases of malignant disease of the body were cases of sarcoma; in none of the 35 was sarcoma noted affecting the cervix only.

The Limitations of the Operation.—Probably the one fact that does most to discredit vaginal hysterectomy for cancer is that an attempt is often made to operate on cases in which (1) the disease has spread beyond the uterus locally; or (2) the disease has already infected the lumbar, iliac, and other glands; (3) or distant organs, such as the lungs or the liver, are also the seats

of malignant disease; (4) or, lastly, some other grave constitutional state exists, such as diabetes or Bright's disease.

If the operator does not carefully avoid such cases, the immediate death-rate will rise, and the ultimate results will be equally unsatisfactory. It is absolutely necessary for us to remember that our duty to our patients, to ourselves, and to the operation demands attention to these and to other such limitations, and that brilliant operating is not identical with good surgery.

In the present series of 35 cases, four proved fatal within a month of the operation, one died of kidney disease, one of shock after a long and difficult operation, and two of sepsis. It is easy to be wise after the event, but probably the one who had chronic interstitial nephritis should not have been submitted to operation, and in one of the other cases circumstances existed which rendered the operation unusually difficult.

Methods of Operating.—An earnest attempt has always been made to render the vulva and vagina surgically clean, the uterus has been well exposed with lateral retractors and drawn down by volsella, the mucous membrane circumcised at the vaginal junction and the bladder stripped up from the cervix until the peritoneal reflexion was recognised. From this point the operations varied: sometimes it was easier and better to open the pouch of DOUGLAS next, sometimes the anterior fold. Having freed the uterus from all but its lateral connections, and having packed DOUGLAS'S pouch with iodoform gauze to act as a temporary protection to the intestines, it is necessary to ligature or to clamp the broad ligaments.

Of the first six cases now presented four were clamped, and of those four, two were fatal, and the other two fatal cases were also clamped; in one of them (No. 30 on the list) the fatal result appeared to be due to necrosis spreading from the clamped tissues which caused sepsis and secondary hæmorrhage on the sixteenth day. This is probably not a mere coincidence, but may be due in part to the unusual difficulty of the operation which made the use of clamps seem necessary, and in part to want of skill, as clamps have been used once only in cases 12 to 46. In the great majority of the cases operated on for malignant disease, the ovaries and tubes were also removed, but in only two cases was there any evident involvement.

Immediate Results of the Operation.—Of the whole 46 cases, four proved fatal within a month; they were all cases of carcinoma.

Case II.—Mrs. D., aged 40, carcinoma cervicis uteri; operation difficult; time, two hours; broad ligaments clamped. Died of shock.

Case III.—Mrs. W., aged 48, carcinoma cervicis uteri; operation easy; time 40 minutes; broad ligaments clamped. Died of kidney disease.

Case XIII.—Mrs. B., aged 64, sent from country with diagnosis of probably early carcinoma. External surface of cervix healthy; advanced carcinoma of body of uterus. Pouch of DOUGLAS obliterated by strong fibrous adhesions, which involved the whole posterior surface of the uterus. The operation was extremely difficult, lasting 2½ hours. The broad ligaments were clamped. Patient died of sepsis on the third day.

Case XXX.—Mrs. R., aged 42, carcinoma of cervix uteri advanced, but uterus moveable. Operation 1 hour and 20 minutes; clamps used. Patient died at the end of a week. In this case necrosis appeared to spread into the tissues beyond the grasp of the clamps. Secondary hæmorrhage occurred, and the patient died of sepsis at the end of a week.

I have ventured to narrate these four cases as illustrating the limitations to which the rightful performance of the operation is subject. Granting that two of them were suitable for operation, the other two were not (the kidney case and the adherent case), and immediately the mortality is altered from 8 per cent. to 4 per cent.

The ultimate result in these cases of malignant disease is equally important, and bears a favourable comparison with other operations for malignant disease, and with the course of the illness if left unchecked.

All the patients have been written to, or seen, with the following results: One patient was well seven years after; one patient was well six years after; three patients were well five years after; four patients were well four years after; five patients were well three years after. Out of the 35 patients 17 are now alive, and without recurrence. The most recent of these was operated on a year ago, and the earliest of them in 1893. The percentage of known recurrences within three years after operation is 7.1 per cent.

The lessons to be learnt from this, and from any similar record, are obvious. Among the chief are:—

1. It is very well worth while to operate on cases of malignant disease of the uterus if the case comes to hand while the uterus is still freely moveable, and there is no obvious extension of the disease beyond this organ.

The disease is commonest about 45 to 50, the average age of the patients now under report being 47—a time when the woman ought to be most valuable to the community.

2. That it is not worth while to operate unless the whole disease can be removed, and the patient has no other mortal disease.

The immediate percentage of death in properly-selected cases should not much exceed five, and it may reasonably be hoped that it may be still further reduced; but the immediate percentage in unsuitable cases will always remain high—(a) from unduly prolonged operation causing shock; (b) from undue bruising and injuries to tissues predisposing to sepsis, and sometimes to secondary hæmorrhage; (c) also from the necessity of using clamps where ligatures cannot be applied.

3. That the responsibility in this matter lies between the general practitioner and the specialist. The family doctor to whom the patient usually first complains should not be contented with ordering ergot, rest, and change of air, but should insist on examining every patient who has profuse or irregular uterine hæmorrhage. Anyone who has a large practice among women, and still more the overworked out-patient official, knows the temptation to listen to a patient's objections and to postpone examination; but, as a matter of conscience, the examination must be made, and if sufficient information cannot be thus obtained, the further aid of the dilator, the curette, and the microscope must be invoked.

Until the idea of "change of life" is eradicated, many valuable lives will be sacrificed. The teachers of gynecology must not be weary in teaching students, nurses, and patients that all hæmorrhage, irregular in time or in quantity, is abnormal and needs treatment, not always operative. Thus gradually there will be an education of public opinion, both lay and professional, and we shall no longer find that the majority of cases of uterine cancer are sent for operation long after all hope is passed, when interference only hastens the inevitable end.

A MIRROR OF PRACTICE.

CHRONIC GONORRHEAL CYSTITIS: UNUSUAL COPIOUS MUCOPURULENT DISCHARGE FROM URETHRA AND BLADDER: CURED BY VESICAL LAVAGE.

BY JAMES R. WALLACE, M.D., F.R.C.S.I.,
Surgeon to the Home Hospital, Calcutta.

MR.—, a Jewish gentleman, aged 30, was admitted into the Home Hospital on the 12th December 1898, suffering from gonorrhœa and gonorrhœal cystitis. He was of middle height, very corpulent, weighing 17 stone. He was in affluent circumstances, of fairly active habits, abstemious, and of good bodily health. He contracted gonorrhœa in a hill station four months before he was admitted into hospital, and was treated by the Civil Surgeon with sandal oil capsules and an injection of permanganate of potash. The disease was apparently virulent, as he suffered considerable pain, with great inflammatory œdema of the prepuce and glans, accompanied by painful enlargement of both inguinal lymphatics and persistent fever, which confined him to his bed for a fortnight. Finding that the acute symptoms were subsiding at the end of this time, his medical attendant endeavoured to stop the very profuse urethral discharge by passing a full-sized catheter through the urinary canal. Within 24 hours febrile disturbance set in, with severe pain in the hypogastrium, and this was attended with a marked discoloration of the urine, which was voided with intense pain. The urethral discharge literally poured from him, and the urine in a day or two became milky-coloured, with a deposit of shreds of mucopurulent matter stained with blood. He was again confined to his bed, and for four weeks, morning and evening, his bladder was washed out with a solution of permanganate of potash. It is remarkable that no improvement followed this line of treatment, though it was persevered with for three weeks. Lavage of the bladder with simple boiled water was now resorted to, and as the patient had lost flesh and was much debilitated, he was given tonics and wines. In a week all pain and febrile symptoms passed off, but a copious discharge from the urethra continued, and the urine, though very free, was charged highly with mucopurulent matter.

Finding that his condition did not improve, he came to Calcutta, and after consulting two other medical men with some relief, he was admitted into the Home Hospital. The discharge was examined under the microscope, and was found to contain gonococci and pus cells in abundance. The bladder was now daily washed out with a warm sterilised solution of boric acid (3 drams being dissolved in an equal quantity of glycerine with a pint of warm sterilised water at 98 degrees). The relief was both marked and immediate. In four days the discharge had almost ceased, and while gonococci were still found in it, the dysuria had completely ceased on the fifteenth day. All signs of discharge had also disappeared, and though the patient felt quite well, he desired that the lavage should be continued for another fortnight. This was done, and he was discharged from hospital on the 12th of January.

Remarks.—The points worthy of interest in this case are: (1) The danger of using a bougie in the early stage of gonorrhœa, and the still greater danger of using a hollow catheter, which is all the more certain of conveying infection to the bladder. (2) The unusual copiousness of the mucopurulent gonorrhœal discharge. (3) The very beneficial effect of lavage with a sterilised solution of boric acid in gonorrhœal cystitis.

A CASE OF LARGE OVARIAN CYST.*

BY ASSISTANT SURGEON T. H. AQUINO, L. M. S.,

Acting Civil Surgeon, Sukkur, Gadag Dispensary, India.

THE following case of ovarian tumour has many parallels with the one reported in the *British Medical Journal* of July 14th, 1900, by Dr. F. A. BALDWIN, of Manchester :—

B. C., a Hindu, aged about 40, was admitted on January 24th, 1895, for an enormous tumour of the abdomen.

History.—She was a mother of several children, the first being born when she was about 13 or 14 years of age. She had been a widow for fifteen years. The labours were said to have been natural: menstruation had also been regular up to about three years before admission, when it first became irregular for a year or so, and then ceased altogether. The general health was said to have been always good. The tumour was first noticed by the patient about five years before admission, but as its growth was slow and painless, it must have existed for some time before it made its presence felt. In consequence of the inordinate size which the tumour had attained, the patient was quite unable to walk or even to stand. In the sitting position, which was the only one she could assume, she had to use the arms as props to the body, and bend the legs for further support. She was unable to lie down, and had to be propped up in bed to enable her to have some rest and sleep.

Condition on Admission.—The face looked small, with hollow cheeks and sunken eyes; the arms were as thin as sticks, the chest wasted, the legs somewhat oedematous, especially the right, the thighs thin. The abdomen was uniformly enlarged and quite dull all over on percussion; the veins over it were dilated and prominent: the circumference at the level of the umbilicus was 5 feet 7½ inches (the height of the woman was about 4 feet 8 inches). The urine had to be drawn off. The bowels were costive.

Treatment.—The tumour was tapped on the evening of January 25th, 1895, and 40½ pints of fluid were evacuated: the operation was repeated next morning, when 35½ pints more were removed. The abdomen, however, still contained a considerable amount of fluid, probably quite as much as, if not more than, was drawn off. The fluid was characteristic of ovarian dropsy; it was thick, viscid, of a dark-brown colour, specific gravity 1018, neutral in reaction, and highly albuminous. The patient felt somewhat relieved after the operation, and did well for a couple of days. Fever then set in, with a feeling of chilliness that was often repeated. She remained in this state for some days, the chilliness never amounting to rigors, and the fever never rising higher than 103°F. After these symptoms had passed off, the abdomen, which had filled again to almost its former size, was once more tapped. After the tapping the patient had a repetition of the chills and fever, and soon began to lose what little strength and flesh she had remaining, and died from sheer exhaustion on March 1st, 1895.

Necropsy.—The tumour filled the entire abdominal cavity. It arose by a short, broad pedicle from the right upper corner and side of the uterus, and was extensively adherent to the abdominal wall on the right side, and to the omentum, liver, and spleen. The inner surface of the cyst, which was unilocular, was inflamed, and presented a rough, uneven surface; it was, in fact, an immense pyogenic membrane. The contents of the cyst consisted of a dirty yellowish fluid, very foetid, with thick flakes of lymph floating in it. Arising from the anterior and middle surface of the cyst wall, inside were five tumours situated side by side, but quite distinct from one another. One of these, the largest, was roundish in form, and measured 4½ inches in length and 3½ inches in breadth; roughly, its size was that of a closed fist; two were of the shape and size of a kidney, and two were more or less round, and of the size of a lemon. These tumours, on section, were found to contain loculi which were filled with a pale-yellow, jelly-like fluid, mixed with some purulent matter. The intestines were flat, narrow, and tape-like; they were displaced to the left side and pressed against the spine. The diaphragm on the right side was very much vaulted, and reached as high as the third rib; on the left side as high as the fourth rib. The lungs were small, but healthy-looking. The apices were forced up into the supraclavicular regions. The weight of the right lung was 7½ ozs., of the left 5½ ozs.; the heart was also small and displaced upwards and to the right, but its tissues, valves, and orifices were normal; weight 4½ ozs. The right ureter was dilated and full of urine; its diameter was about 1½ in.; the left ureter was normal; the kidneys also appeared normal, and weighed about 3 ozs. each. The spleen was adherent to the cyst wall, but normal in structure; weight 6½ ozs. The liver was displaced upwards as high as the third rib; it had almost a globular shape, with its under surface hollow and cupped; weight 2 lbs. ½ oz. Uterus normal in shape, size, and position; left ovary, fallopian tube, and ligaments normal; the same structures on the right side were obliterated or absorbed in the sac. The rectum and vagina were normal; the cyst wall was very thick, and weighed, together with the five colloid tumours arising from it, mentioned above, 5 lbs. 4 ozs. It was sent to the Grant Medical College Pathological Museum, where it is preserved.

The repeated chills and the persistent low fever seemed to indicate inflammation of the sac as the result of tapping, and the necropsy confirmed this supposition. The operation had to be undertaken as a matter of necessity, in order to relieve the tension and other symptoms caused by the enormous amount of fluid, about 14 or 15 gallons, present in the abdomen. Ovariectomy in this case seemed to be quite out of the question.

A CASE OF ABDOMINAL GESTATION: DEATH.

BY M. N. GOVINDEN NAIR, C.M.S.,

Medical Officer, L. F. Dispensary, Badvel, Cuddapah District.

THAT dreadful complication of human conception, viz., extra-uterine gestation, is fortunately such a rare occurrence that I need hardly apologise for submitting for

* Reports on Medical and Surgical Practice in the Hospitals and Asylums of the British Empire.

publication the notes of a case which I had the misfortune to have had under my observation lately.

LINGAMAH, a married woman of the labouring class, who had had five safe deliveries previously, was brought to the Local Fund Dispensary at Badvel on the 9th December 1900, at 3 P. M., for confinement from a village 20 miles off. The history was that the woman was in full term of her pregnancy (which was verified by subsequent observation), and that she was seized with a sudden pain in the abdomen four days previously, followed by discharge of a thick fluid *per vaginam*. The pain never appeared again, and no progress being noticed in the labour, and the strength gradually failing, she was brought to the dispensary.

On arrival she was found in a moribund state. She was unconscious; the temperature was 100° F.; the body was covered with a moist, clammy sweat; the pulse was small and thready; the eyes not responding to touch, and there was a very offensive smell about her. An examination *per vaginam* was, however, made, but no parts of the fœtus could be felt even after the most careful examination, whereas it could be distinctly felt under the disturbed skin and muscles of the abdomen, which gave me the idea that the case might be one of abdominal gestation. The fœtus was motionless, and evidently dead. The condition and circumstances of the case were such as to preclude any operative interference. The end, though momentarily expected, did not come until 2 o'clock next day, when she expired quietly of exhaustion.

Cutting a dead body is generally opposed to the native sentiment, but in a case like this, fortunately, there is an exception based on the superstitious belief that a woman dying with a fœtus in the womb has no salvation. I had therefore no difficulty whatever in inducing the relatives of the deceased woman to agree to a *post-mortem* examination.

On opening the abdomen about a pint of dark putrid fluid escaped, and a fully developed male fœtus was exposed in a thin, black, gangrenous membrane which had ruptured. The fœtus was also found to be in an advanced state of decomposition, with large blue bullies all over the body. The attitude of the fœtus was exactly the same as in a case of normal uterine gestation. The placenta was small and thin, being only a third of the size of a normal organ, and it was in a state of decomposition too. It was found lying detached in the space between the uterus and the bladder. The cord was about one foot long. The bladder was very much thickened with large distended veins. The uterus had also undergone some changes. It was enlarged, being about 10 inches long and 6 inches broad, with the wall about half an inch thick. The mucous membrane was hypertrophied and vascular. In the anterior wall of the cervix there was a hole a little bigger than a rupee in size, which seems to have been the result of inflammation and ulceration, caused by the constant pressure of the head. There was nothing unusual about the fallopian tubes or ovaries, except that they were also somewhat enlarged.

Of the causes of the deviation in the natural progress of the impregnated ovum, nothing is definitely known, and I must own that my observations in this case cannot make such knowledge any the better. Opinion is divided as to the chances of an extra-uterine gestation going to the full term. Some authors are of opinion that full term is reached in a large majority of cases, all varieties considered; while others believe that chances of rupture of the cyst increase with every succeeding month. The case under notice will be found interesting as one which has gone on to full term with a fully developed fœtus, and as having induced typical changes in the womb in the shape of enlargement and development of the mucous membrane into what looked like decidua.

A CASE OF TRAUMATIC EPILEPSY CURED BY OPERATION.

BY JAMES ARMOTT, M.D.,

Deputy Medical Officer, Workhouse Infirmary, Brampton, Cumberland.

THE following case is perhaps worthy of record, partly on account of the number and severity of the convulsions and their immediate relief by operation, and partly also from the rather unusual condition of the skull found at the seat of injury:—

The patient, T. N., single, 27 years of age, a mason, was admitted to the Workhouse Infirmary on December 16th, 1899, having been found unconscious by the police.

Previous History.—Two and-a-half years previously he fell from a scaffold about 20 feet on his head, and evidently sustained a fracture of the skull. Six months later fits began to make their appearance, and have continued ever since. Slight at first, they have increased steadily in severity. There has been, in addition, constant headache since the accident.

Condition on Admission.—Since admission he has had from twenty to twenty-five fits every day. During the intervals he lies in a dazed semi-conscious condition. On the left side of the skull, corresponding almost exactly with the position of the parietal eminence, there is a depression about 1½ inch in diameter, over which there is hyperæsthesia, but no pulsation. Slight pressure in this situation at once causes a fit. There is paresis of the right arm and leg. On examination of the right fundus, there is seen to be well-marked optic neuritis. The patient speaks with difficulty. The temperature is normal and the pulse 62.

Operation.—On December 22nd, 1899, the head being shaved, I turned down a large semi-lunar flap of scalp. On laying bare the depression, it was found to be entirely devoid of bone, the periosteum and dura mater being apparently welded into one. This was firmly adherent to the brain, and on removing it thick prolongations were seen dipping in between the convolutions. These were taken away, leaving the brain pulsating freely. The flap was then replaced, stitched, and dressed antiseptically. Just before being put on the table the patient had a severe fit. The next day he said he "felt quite different." He had had no headache or fits. The grip of the right hand was much stronger, the temperature normal, the pulse 80. The wound, when dressed four days later, was found to be completely healed.

I saw the patient on December 3rd, twelve months after the operation. He tells me he has never had a headache or a fit since. His right arm and leg are quite strong, and the optic neuritis has disappeared. He is, in fact, perfectly well.

Indian Medical Record.

13th February 1901.

RELATIONSHIP BETWEEN AFFECTIONS OF THE FEMALE GENITALIA AND NEUROSES AND INSANITY.

IN a paper contributed to the *Edinburgh Medical Journal*, Dr. H. MACNAUGHTON JONES, M.D., M.CH., M.A.O., F.R.C.S.E. & L., discusses at some length the subject of "Affections of the Female Genitalia as Causal Factors in the Etiology of Neuroses and Insanity and their special bearing on the Operative Treatment of the Insane." We can afford space only for the essentials of this valuable contribution. The following are shortly the conclusions at which the writer arrives: (1) Where, in an insane person, ovulation and its external manifestation, the menstrual discharge, are absent or erratic, the erraticism or absence may be a consequence of the general and insane condition, and not a causal factor in its production; but under any circumstances such abnormal menstruation appears to have an aggravating effect on the insanity, and there is sufficient evidence to strengthen the belief that when such irregularity exists—especially if it be due to a pathological cause—it should be treated therapeutically or by operative measures. (2) The question of a gynecological examination of an insane woman must be a matter for the discretion of the psychologist, influenced by the gynecological view as to its expediency from the signs and symptoms present in the sexual organs. For many reasons as a *universal* practice it was not warrantable. (3) Sufficient evidence was now advanced to justify the removal of the adnexa or tumours of the uterus in insane women when there were gross lesions of the former or tumours of the latter. Here, again, such operations must be advised according to the psychological condition of the patient and the type of her insanity. (4) From a mass of evidence, it did not appear that there is in healthfully minded women, who suffer from diseases of the genitalia, any special risk of post-operative insanity. On the other hand, if there be a psychopathic predisposition, which has existed prior to, and independently of, the sexual disease, there is in such cases a larger percentage of post-operative mental disturbance than follows other operations. In such women the prudence of a radical operation may have to be carefully discussed. The post-operative mental effect did not appear generally to be of a serious or permanent nature. (5) It may be generally affirmed that when mental disease of a graver type follows upon sexual disorder, there has been in the woman affected an underlying and often unrecognised psychopathic predisposition: the disorder of menstruation or the disease in the genitalia completing the chain of the vicious circle needful for the final manifestation of the mental condition. (6) The relation of aberrant sexual function or a disorder of menstruation to any criminal act ought to be taken into consideration in determining the responsibility of the woman.

The practical effect of this communication might be summed up in three questions formulated by the writer, and the replies thereto:—

A. What are the indications for a gynecological examination of women who are suffering from any form of mental aberration, and under what circumstances is such examination of an insane woman expedient and justifiable? Dr. ROBERT BARNES had advocated the elimination by examination, if necessary, of the presence of any sexual disorder in a woman before confining her to an asylum. This was a rational conclusion. It did not necessarily involve an internal examination of the genitalia, for an inquiry into the past history of the patient, together with the circumstances under which the first evidences of alienation appeared, would generally exclude the possibility of there being any interference with the discharge of the functions of the sexual organs. Such an inquiry would also assist in arriving at a conclusion that symptoms of mental disturbance preceded any interferences of function, or *vice versa*. Such a careful investigation giving negative results would influence against the necessity for proceeding further. Also, obviously, in a fair proportion of cases, there would be a knowledge of other causes predisposing to and producing insanity. For instance, the frequently occurring one of heart disease as a physical, and disappointment in love affairs or mental worry as a psychical cause. Or, again, the habit of masturbation might be verified. Such careful inquiry would also elicit the proofs, both by symptoms and signs of previous pelvic disease, whether in the uterus, adnexa or external genitalia. Should this exist, there was a clear indication for the determination of the extent and nature of the disease, and its probable effect on the mental condition. The age of the patient and her state, whether married or single, would also influence. The disorders of menstruation, so frequent during the years of adolescence, had commonly no local pathological explanation. The causes of these were, however, often congenital. A persistent dysmenorrhœa, menorrhagia or metrorrhagia would certainly indicate the need for examination as would a suspicion that the womb was retroverted. Permanent non-appearance of the menses would arouse suspicion of atresia of either uterus or vagina, and the possibility of partial or complete absence of the genitalia had to be recollected. In married women there was not the same reluctance to examination; the causes of disorders of menstruation were more likely to be pathological, and consequently the indications for examination were generally more obvious. During middle life also there were all the parturient and puerperal sources of insanity requiring investigation. At the advent of and during the menopause, should any striking deviation from the natural course of cessation of menstruation precede or accompany the insanity, an examination should be made for the same reason that it was advised in ordinary cases, namely, to escape the error of overlooking any serious pathological condition of the adnexa and uterus. That being so in the case of the sane woman, it was even more so in the case of the insane, where there was the additional reason of the mental condition being attributable to any disease that might be present.

B. Is operative interference in cases of pathological changes in the genitalia of insane women justifiable, and under what circumstances? All the evidence gathered from the most eminent sources showed that such interference was called for (1) when, on weighing the etiological factors in the causation of any particular case, they point to a causal relationship between the sexual disorder and the disturbance of mentalization; (2) when observation of the patient shows that the pelvic disorder aggravates the insanity by intensifying delusions, directing the mind morbidly to the sexual organs, increasing the severity of periodical outbursts, or by the influence on the physical well-being, preventing improvement of the mental state. It was for the psychologist to decide the most favourable time for operation and the contraindication that may be presented by the phase and type of the insanity.

C. Do operations on the female genitalia specially predispose to post-operative insanity, and do operations on the genitalia of insane women tend to aggravate the mental symptoms? The writer shows from the opinions of the most eminent authorities that in a healthy woman there was never any disturbance after an operation: there was always "some predisposition." The writer had never personally seen any injurious mental consequence follow a gynaecological operation in a healthy woman: in only two of his cases, in whom symptoms of insanity appeared, one had previously been in an asylum, and the other, an official in a private one, had been a typical neurasthenic for some years. And it certainly did not appear from the published records of operations performed on the insane that the symptoms had been thereby aggravated, save in very few instances, and in these the effect did not appear to have been permanent. Dr. MACNAUGHTON JONES hoped that by the collaboration of those psychologists in charge of large public asylums and private institutions with experienced gynaecologists, aided by the intelligent assistance of those who have had the previous charge of patients admitted into these institutions, more certain and reliable data would be arrived at, and thereby treatment of the female insane would be less empirical, and less hampered by routine, than at present. The desirability of the triple concert of the patient's physician with the expert psychologist and gynaecologist, in order to arrive at more complete conclusions—clinical, physiological and pathological—had been insisted on by so distinguished an authority as Professor HEGAR, who had said "with such a large supply of material as was found in our great insane asylums, valuable results might confidently be looked for."

ANNUAL REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR THE YEAR 1899.

II.

THE EUROPEAN ARMY OF INDIA.

The above Report says:—

"The health of the European army of India was much better in 1899 than in 1898," and again it "was much better in 1898 than in 1897." From this it appears that the sickness amongst European troops has steadily

diminished during the last two years, and that the healthiness of the year 1899 was quite exceptional, if indeed not phenomenal.

A glance at some of the figures seem to bear out this view.

The admission-rate, that is, the number of admissions to hospital per thousand of the total strength, was 1,148.7. There were 1,148.7 admissions for every thousand men serving in India. Large as this number appears, it is small compared with other years. In fact it is the smallest since 1870, the furthest back we are able to refer to. The nearest to it was 1877, with an admission-rate of 1,257.3.

The admission-rate for venereal diseases was 313.4, the smallest since 1884, when it was 293.9; the highest figure in the meantime was 522.3 in 1895.

The admission-rate for enteric fever was 20.6, the lowest figure since 1893, when it was exactly 20; the highest figure in the intervening period having been 36.9 in 1898. The year 1899 is, in fact, remarkable, in as far as enteric fever is concerned, for it marks the first check to the steady rise which began in 1894 and has been an annual event ever since.

CAUSE OF THE UNUSUAL HEALTHINESS OF 1899.

It seems a for cry to go to South Africa to get an explanation for the unusual healthiness of the year 1899; yet it was indirectly due to the war in South Africa.

It is a well-established fact that young soldiers are more liable to disease than old soldiers. This fact extends not only, as is too often supposed, to enteric fever, but universally to all diseases; and not only to tropical climates, but to all climates.

The question has been carefully worked out in the statistics of the French army, and we recently published the figures showing that soldiers under one year's service are almost twice as liable to all diseases as soldiers of over one year of service.

It is to the absence of the young soldier, owing to the excessive demands made by the South African war, that the unusual healthiness of the year 1899 must be chiefly attributed.

The strength of the European army did not differ much from the strength of the previous year—67,697 against 67,741. But the number of men who arrived in the country, mostly of course young soldiers, was only 3,369, against 16,911 in 1898. The smallness of this figure has no equal since 1870, the earliest year to which we can refer. The next smallest number is 7,568 in 1875. So we see that in this respect the year 1899 was altogether exceptional.

If this conclusion is true, the converse must be equally so. We will almost certainly find that when the large number of time-expired men, old soldiers who have been detained beyond their proper time in India, are sent home, and their places taken by an unusually large influx of young soldiers, that there will be a correspondingly large increase in the amount of sickness.

This may be confidently expected in the year 1902.

INVALIDING.

The total number of men invalided in 1899 was 2,142, against 2,580 in 1898. Although this is an improvement on the preceding year, when compared with the average of 10 years, it is by no means satisfactory. Thus in the 10 years, 1889-98, 27.50 men were invalided out of every 1,000, while in 1899 the number was 31.64 per thousand. For reasons that are fairly obvious, the invaliding rate was not affected by the small number of arrivals in the country. In fact the number of men invalided before they had been one year in the country was higher than in 1898—350 against 295; but these must have consisted for the most part of men who came out the preceding year, that is, in 1898.

There can be no doubt that the number of men invalided has shown a decided tendency to increase of late years, and this appears to us an astonishing and disquieting feature, considering the increased facilities that now exist for sending sick and weakly men to the hills.

OF WHAT USE ARE HILL STATIONS IN INDIA.

It may well be asked, how is it that the large number of Hill Sanitaria all over the country have not tended to reduce the number of men annually requiring change to England, or if the best possible use is made of these expensive establishments? Of the large number of men sent home, only 31 per cent. were sent home as unfit for further service! What of the other 69 per cent.? Would not a change to some Indian hill station, in a large number of cases at any rate, have been as beneficial as a change to England? We would like to know what powers the local medical authorities possess for controlling the increasing flood of invaliding, and if such powers as they possess are properly exercised.

Presumably invaliding is no tax upon the purse of the Indian Government, or we might expect to see the present somewhat lavish scale on which it is carried out restricted.

EXCESSIVE SICKNESS.

Amongst the regiments and corps to which special attention is drawn on account of their unhealthiness, we find two that were stationed in the neighbourhood of Calcutta.

The 29th Battery, *sic*, (it should, we believe, be Company) Southern Division, Royal Garrison Artillery, which had the second highest constantly sick-rate was stationed at Barrackpore, while the 1st Battalion, Royal Irish Rifles, which had the fourth highest death-rate, was stationed at Dum-Dum and Calcutta. Barrackpore and Dum-Dum appear to possess an unenviable notoriety in many respects. The most unhealthy corps in the army, however, was the 3rd Hussars at Lucknow, amongst which enteric fever was unusually prevalent; there were 46 admissions and 10 deaths.

ENTERIC FEVER.

As usual a considerable portion of the Report is allotted to the discussion of enteric fever, and the most important recent advances in our knowledge of the subject mentioned.

According to ELLIOTT SMITH, the disease is no longer to be considered as an intestinal disease, but as a modified form of septicaemia. "It is a septicaemia, in that always, and in all cases, the bacilli pass into the blood and then into the various organs, and in that the symptoms, excepting as far as they are intestinal, are referable to the poisons there produced." RANKIN regards "the finding of the bacillus in the stools as the only certain sign of enteric fever."

Again, we read that "there is no proof that the enteric bacillus can multiply outside the body," but "that the bacillus has great powers of resisting the powers of desiccation; remaining alive, it may be, for over a year in the dried condition, it becomes easy to understand how bacilli eliminated from the body may pass into the atmosphere in the form of dust, and cause disease at long periods after every fresh source of infection has been really removed."

From this it may be gathered that the endeavour to find the cause of every case in the water-supply is being given up, and that other sources of infection are about to receive their fair amount of attention.

The inventor of the dust theory is to be congratulated on having discovered a medium that is likely to exhaust the resources of investigators, if not their patience, and to afford a fruitful field for controversy and speculation for years to come.

The opinions of a number of medical officers as to the cause of enteric fever in their stations are given, the variety of different ideas on the subject is as usual considerable, and a number of references are made to various local insanitary conditions.

We gather that the boiling of the drinking water is in many places carried out in such a faulty way, that it is more a source of danger than anything else. It would appear that though the boiling is ordered, no facilities are provided for carrying out the order.

At Jhansi it is reported that no benefit has resulted after 2½ years' trial from the addition of permanganate of potash to the water. At Jullundur, on the other hand, it is mentioned as a cause of the decrease of the disease. The dirtiness of troop trains is alluded to by another medical officer, who thinks that a little more cleanliness would not be misapplied in this direction, and also that pure aerated drinks might be supplied en route.

The various opinions are at least interesting, and show that medical officers study the question of causation as far as their means go; indeed some appear to be possessed of an unbridled enthusiasm which rather oversteps the mark, and tends to degenerate into a sort of monomania. This would be harmless if its effects fell only on the individual. But when we read that one medical officer alone sent for analysis to Professor E. H. HANKIN, Chemical Examiner and Bacteriologist, N.-W. Provinces and Oudh and Central Provinces, 311 specimens of water, 52 specimens of earth collected in or near the commonest filth pits, 22 bottles containing flies, caught at weekly intervals in cook houses and latrines, and 12 samples of water in which regimental cooks and sweepers had washed their hands, we cannot help wondering what would be the fate of the overworked Professor if every medical officer's demands on his time were of a similar scale!

BACTERIOLOGICAL WORK.

This part of the Report contains some interesting sanitary reports and results of bacteriological investigations carried out by officers of the R. A. M. C. specially appointed for the work.

The investigations of one of these officers extended from Umballa to Bangalore, and from Aden to Suwebo in Burma; so that his post cannot be said to be a sinecure. In bacteriological work, however, the Government of India, as is well known, is a Shylock, who expects more than his pound of flesh.

MALTA FEVER.

Only one case of this disease found its way into the returns. In view of the frequent allusions that have been made to this disease in the lay papers, it is interesting to note that the Sanitary Commissioner advises caution in accepting these cases as genuine.

COMMENTS AND NEWS.

THE LAST ILLNESS OF QUEEN VICTORIA.

THE *British Medical Journal* says:—We are enabled to publish the following authoritative account of the last illness of Queen VICTORIA:—

The Queen's health for the past twelve months had been failing, with symptoms mainly of a dyspeptic kind, accompanied by impaired general nutrition, periods of insomnia, and later by occasional slight and transitory attacks of aphasia, the latter suggesting that the cerebral vessels had become damaged, although Her Majesty's general arterial system showed remarkably few signs of age.

The constant brain work through a long life of Royal responsibilities, and the Imperial events, domestic sorrows and anxieties which have crowded into later years, may no doubt be held in some measure to account for this discrepancy between the cerebral and general vessel nutrition. The thoracic and abdominal organs showed no sign of disease.

The dyspepsia, which tended to lower Her Majesty's originally robust constitution was especially marked during her last visit to Balmoral. It was there that the Queen first manifested distinct symptoms of brain fatigue and lost notably in weight.

These symptoms continued at Windsor, where, in November and December 1900, slight aphasic symptoms were first observed, always of an ephemeral kind, and unattended by any motor paralysis.

Although it was judged best to continue the negotiations for Her Majesty's proposed visit to the Continent in the spring, it was distinctly recognised by her physicians, and by those in closest personal attendance upon her, that these arrangements were purely provisional, it being particularly desired not to discourage Her Majesty in regard to her own health by suggesting doubts as to the feasibility of the change abroad to which she had been looking forward.

The Queen suffered unusual fatigue from the journey to Osborne on December 18th, showing symptoms of nervous agitation and restlessness which lasted for two days. Her Majesty afterwards improved for a time, both in appetite and nerve tone, in response to more complete quietude than she had hitherto consented to observe.

A few days before the final illness, transient but recurring symptoms of apathy and somnolence, with aphasic indications and increasing feebleness, gave great uneasiness to her physician.

On Wednesday, January 16th, the Queen showed symptoms of cerebral exhaustion. By an effort of will, however, Her Majesty would for a time, as it were, command her brain to work, and the visitor of a few minutes would fail to observe the signs of cerebral exhaustion.

On Thursday these symptoms were more marked with considerable drowsiness, and a slight flattening was observed on the right side of the face. From this time the aphasia and facial paresis, although incomplete, were permanent.

On Friday the Queen was a little brighter, but on Saturday evening there was a relapse of the graver symptoms, which, with semicomas, continued until the end. It is important to note that, notwithstanding the great bodily weakness and cere-

bral exhaustion, the heart's action was steadily maintained to the last, the pulse at times evincing increased tension, but being always regular and of normal frequency.

The temperature was normal throughout. In the last few hours of life paresis of the pulmonary nerves set in, the heart beating steadily to the end.

Beyond the slight right facial flattening there was never any motor paralysis, and except for the occasional lapses mentioned, the mind cannot be said to have been clouded. Within a few minutes of death the Queen recognised the several members of her family.

THE MEDICAL DEPARTMENT OF THE QUEEN'S HOUSEHOLD.

THE medical department of Her Majesty's household in England at the time of her death was as follows:—

Physicians in Ordinary: Sir Edward Henry Sieveking, M.D.; Sir James Reid, Bart., K.C.B., M.D.; Sir Richard Douglas Powell, Bart., M.D. *Physicians Extraordinary*: Sir Alfred Baring Garrod, M.D., F.R.S.; Sir Samuel Wilks, Bart., M.D., F.R.S.; Sir William Henry Broadbent, Bart., M.D.; J. E. Pollock, M.D.; Sir Thomas Barlow, Bart., M.D. *Sergeant Surgeon*: Lord Lister, F.R.S. *Surgeons Extraordinary*: Sir T. Smith, Bart., F.R.C.S.; T. Bryant, F.R.C.S.; F. Treves, F.R.C.S. *Physician to Household*: Sir T. Barlow, Bart., M.D. *Surgeon to Household*: Rickman J. Godlee, F.R.C.S. *Surgeon Apothecary to Her Majesty and Apothecary to the Household*: Sir Francis Henry Laking, K.C.V.O., M.D. *Surgeons and Apothecaries in Ordinary to the Household at Windsor*: William Fairbank and W. A. Ellison, M.D. *Ditto at Osborne*: William Hoffmeister, M.D., and H. E. W. Hoffmeister, M.B. *Surgeon-Oculist*: George Lawson, F.R.C.S. *Surgeon-Dentist*: Sir Edwin Saunders, F.R.C.S. *Dentist to the Household*: Edwin T. Truman. *Chemist and Druggist*: Peter Wyatt Squire.

All these offices of course became extinct at the Queen's death.

MORE BAD SURGERY IN THE MEDICAL COLLEGE HOSPITAL.

MAY we ask the Inspector-General of Civil Hospitals, Bengal, why the mortality of the wards under the care of the "Professor" of Surgery is so abnormally high? Will he have the goodness, in the interests of patients in the wards of that officer, to demand a detailed report of the deaths in the surgical wards under Dr. E. D. MURRAY's care? For example, why should a case undergoing an operation for simple hydrocele, die of septicæmia? Why should simple (intracapsular) fracture of the neck of the femur, terminate in death by septicæmia? Why should similar cases of this type be faultily diagnosed? Why should a simple wound of the hand, in these days of successful antiseptic surgery, necessitate amputation at the upper third of the arm, and why should such a case end fatally? These are straight questions. They demand straight answers. But why, we ask again, are human lives being sacrificed for lack of skilful surgery in the Medical College Hospital? Why not admit the folly and the error of putting in the wrong man into the Chair of Surgery and of manufacturing by a gazette process a Surgical "Professor" from badly tempered material? Again, we say, a public inquiry is demanded into the inner working of the Calcutta Medical College Hospital, and we respectfully request that such investigation be now made.

PROFESSIONAL CARDS AND SIGNS.

The *Philadelphia Medical Journal* says:—By the same mail we receive three letters concerning three phases of "professional advertising"—all relating to methods of making known the specialty. The first asks:—

"If a man should advertise in a medical journal that he did clinical microscopy for other doctors at certain rates, would it be ethical, and would it be in good standing?"

We think it highly desirable, as well as absolutely inevitable, that the best professional work should be done by those exceptionally able and fitted to do it. The experts and the specialists under proper professional rules and ideals are pushing forward professional progress not only theoretically, but practically. That they should be paid for their special work goes without saying. In answer to the foregoing question, the answer Yes would seem most clear.

The second inquirer asks if the words "surgery and consultations," or "practice limited to surgery," placed upon his professional cards and the circulation of these cards strictly limited to the profession, would be "professional." The third correspondent writes as follows:—

"Many complaints are made that physicians who limit their practice do not confine themselves to their specialty. It is unfair to the general practitioner that the specialist should attempt to treat a disease that does not pertain to his specialty. For instance, a physician a few months ago sent a patient, who had recently lost the sight of one eye, to an oculist, who made a diagnosis of syphilis. The patient was then sent to his family physician, under whose treatment he completely recovered. As the reputable specialist depends very much on the support of the general practitioner for patients, it is his duty to place himself in such a position that every patient who enters his office will know that he makes a specialty of one thing, and does not pretend to treat anything else. He can do this only by having his specialty on his sign and on his office door. For six years I have had my specialty on my office door, and not more than once a year do I have a patient come to my office for anything that does not pertain to my branch of medicine.

"If every specialist would do this, there would be little opportunity for him to do anything but special work. The general practitioner, also, would feel more like sending his patients where they may see that the physician to whom they are sent limits his practice, and is not simply a physician who knows more about everything than the family physician."

At first sight these arguments seem logical. Upon closer examination we think they are more than neutralized by others. Even in the heart of great cities it is so exceptional for patients to err, *e. g.*, in seeking for the services of an oculist when they wish an obstetrician, that the emphasis of the need for specialist signs or notices may easily be exaggerated. So far as concerns one's professional brethren, even in cities they soon learn the specialty and desires of each as to practice. The doubt as to whether one honorably sticks to his specialty is, or may be, easily cleared up. One of our oldest and most honorable national medical societies makes it an invariable rule not to accept as a member any applicant who, on sign or card, makes known the fact that he is a specialist. We think the rule a wise one. All such methods of advertising are outgrowths of the commercialism of medicine, of looking upon the cure of disease as a business, and of thinking of the patient's ability to pay before determining as to the treatment. Medicine, it cannot

be too often urged, is neither business nor knowledge nor success; nor is it all three combined. All three are more or less necessary but subordinate parts or bases of the professional life, but skill, the cure of disease, *the art of medicine*, is something far different and higher. Can we not keep the old, simple, kindly, personal relations with our patients, and also with our professional brethren? It surely is not necessary to mechanize our calling and harden it after the manner of the world in military and commercial life. Let us continue on our older gentler and human way of quietness and modesty, wherein we need not placard our peculiar abilities. Whatever tends toward, or is in danger of being construed as advertising, does us no good in the long run, and is destructive of the true ideal of the physician. However great the skill or the knowledge, it is our most honorable pride that these qualities should but light us on the way of love and beneficence.

THE FATHER OF MODERN ELECTRICITY.

DR. WILLIAM GILBERD, Queen Elizabeth's physician, is at length to receive honour in his own country. Three hundred years have elapsed since Gilberd laid the foundations of electrical science in his famous work *De Magnete*, published in 1600. It is time that Englishmen should do some honour to the man who was called by Priestley "the father of modern electricity," and by Poggendorff "the Galileo of magnetism." Gilberd was born at Colchester, and received his early education in the Grammar School of his native town. In due course he proceeded to St. John's College, Cambridge. Soon after taking his first degree in 1560 he became a Fellow of his college, where he remained in residence, taking part in its affairs, for ten years. As was said by Mr. Joseph Larmor in his presidential address to the Section of Mathematical and Physical Science at the last meeting of the British Association, all through Gilberd's career, both at Colchester and afterwards in London, where he attained the highest position in his profession, he was an exact and diligent explorer, first of chemical and then of magnetic and electric phenomena. Hallam, in his *History of European Literature*, says of Gilberd: "In his Latin treatise on the magnet he not only collected all the knowledge which others had possessed, but he became at once the father of experimental philosophy in this island." Mr. Larmor adds that no demur would be raised if Hallam's restriction to this country were removed. It is extraordinary that such a man should have so long remained without any public memorial in his own land, and we are pleased to be able to announce that this reproach is about to be removed from us. The medical profession at Colchester—the birth-place and burial-place of Gilberd—have the honour to be the originators of the first proposal to do suitable honour to be the originators of the first proposal to do suitable honour to his memory. At a meeting recently convened by the Mayor of Colchester (Mr. Claude E. Ngerton-Green), and addressed by Dr. Elliston (President of the British Medical Association), Professor Silvanus Thompson, Dr. Fenn, Mr. Henry Laver, Mr. Edgar A. Hunt, and others, it was decided that the medical men of Colchester should be invited to erect a full-length marble statue of Gilberd, to occupy a niche in the main facade of the new Town Hall of the borough. Mr. Henry Laver, F. S. A., was appointed Treasurer to the movement, and has already received promises of subscriptions amounting to £180. The minimum total required for the statue is £150, and it may be hoped that no difficulty will be experienced in raising something more than this, so that the statue may be made worthy of Gilberd and of the profession to which he belonged. Lord Kelvin has, we understand, written, expressing his cordial approval of the proposed memorial.

TRADITIONAL JEALOUSY OF THE CIVIL SERVICE OF INDIA.

AN I. M. S. man, writing to the *British Medical Journal*, says:—The traditional jealousy of the Civil Service of India has once more worked to the serious detriment of the Indian Medical Service. The greatest attraction of the latter is—or more correctly speaking was—the likelihood of lucrative private practice in course of time; but now that the medical colleges in India are turning out so many highly qualified men, practice among the middle class of natives is rapidly becoming a thing of the past, and only men with the highest reputations add materially to their incomes by private practice among the richer natives or rajahs, the fees being few, though sometimes large. The civilian, however, who draws from one to two thousand rupees a month, after a few years' service, grudges to his much less highly paid medical colleague an occasional high fee, and an order has just been issued by the Government of India prohibiting any fee of Rs. 2,000 and over being taken without the express sanction of the Government in each case. Thus a service medical officer cannot take even such a fee as a London consultant would obtain for a few hours' railway journey into the country, even if he was attending a prince many hundred miles from his station, and had lost possibly several days' practice. When the civil authorities find that they have prevented by their short-sighted and dog-in-the-manger policy good men from entering the service and have themselves, together with their families, to depend on a less highly qualified set of doctors than they have hitherto had the advantage of, they will discover their mistake when it is too late to undo the mischief.

THE DEFINITION OF THE WORD "OPERATION."

THE definition of the word "operation" would at first seem sufficiently clear. And yet, when rigidly scrutinized, it is by no means so. A recent medico-legal case brought several errors and indistinctions to attention, and upon collating and classifying the definitions given in a large number of lexicons, we find noteworthy differences and mistakes. All but one or two incorporate one or more errors, and there is one that gathers and endorses all of the five following inaccuracies:—

1. An operation is performed by an authorized surgeon, or by a legalised practitioner of medicine. An instant's attention shows that an operation may be performed by a non-medical person.
2. It is performed by one person upon another who is the patient. But, as we all know, an operation may be performed by and upon oneself.
3. It is performed by means of surgical instruments. Operations, however, are performed every day without instruments.
4. It is manual. But every surgeon knows of operations done without the use of the hands.
5. It is with the object of relieving disease or restoring health. And yet in cosmetic operations, in vaccination, in criminal abortion, and in malingering, the object is not the restoration of health.

In the presence of these criticisms almost the only definition that will undergo testing is the simple one that an operation is a *surgical act* (or *procedure*). The essence of the matter appears to be expressible by one word which no dictionary, so far as we know, has caught. The distinctive difference between all other therapeutic measures and surgical ones resides in the word *mechanic*. This is manifest in the etymology of the word *surgeon*—one who works with

the hand. But though a surgical act may be carried out by other means than the hands, the nature of the procedure is mechanic in contradistinction to other means essentially chemio or physiologic.

OFFICIATING PROFESSOR OF ANATOMY IN CALCUTTA.

MAJOR DAVID MACBETH MOIR, I.M.S., has been appointed to officiate as Professor of Anatomy to the Calcutta Medical College and Surgeon to the College Hospital during the eight months' absence, on leave, of Lieut.-Col. E. HAVELOCK CHARLES, I.M.S., who leaves Calcutta for a tour through Egypt, Europe, and America on the 25th instant. Dr. MOIR is M.B., C.M., Edin., 1885. He passed into the I.M.S. in 1888 second on the list. He held formerly the post of Demonstrator of Anatomy in Edinburgh and obtained a medal from Netley. He has for some years been one of the resident medical officers of the Presidency General Hospital, but he has no record of good surgery. The selection, however, is probably a good one so far as anatomy goes, and let us hope the surgical experiences will not equal in brilliancy (!) the exploits of Dr. R. D. MURRAY, who, by the way, was another "selection" from the former resident staff of the Presidency General Hospital.

SENTENCE OF JAMES ARMSTRONG, THE BOGUS M.D. MAN.

THE *Medical News of New York* says:—JUDGE KOHLSAAT has imposed a sentence of one year in jail and a fine of \$500 on JAMES ARMSTRONG, President of the Metropolitan Medical College. The defendant was convicted recently of using the mails to defraud in connection with a "diploma mill." Sentence against THOMAS ARMSTRONG, who was convicted, and JOHN H. RANDALL, who pleaded guilty to the same offence, will be passed at the next term of court in March. JAMES ARMSTRONG made a hard fight, and he now threatens to prolong the legal battle in the higher federal courts. The ARMSTRONGS first began business in 1895 with the "Illinois Health University." This was a "diploma mill" on a small scale, and the Illinois State Board of Health, through its secretary, soon closed the doors of the bogus institution. Then the charter for the Independent Medical College was used. The charter of the college was revoked some years ago. The same kind of "grafting" was continued under the name of the Metropolitan Medical College, although a restraining order was issued in the State court against the officials doing business under this charter.

THE MOSQUITO FAMILY.

THE word mosquito has no scientific import. Derived from the Spanish or Portuguese, it simply means little "fly"; it is used popularly to denote a gnat which bites, and most gnats bite when they have a chance. The word is sometimes extended to include certain midges. The dipterous family, Culicidae, to which the gnat belongs, contains, according to Major GILES, some two hundred and forty-two species divided among eight genera. The great majority of species (some one hundred and sixty), however, belong to the genus *Culex*; *Anopheles* includes thirty, while the remainder are divided among the other six genera, none of which are large. The collections which have recently been made at the British Museum are said to contain ten species of *Anopheles* new to science, so that, if all Major GILES' species are accepted, we have a total of some forty species of the genus which has been hopelessly convicted of being the medium by which the malaria parasite is transmitted from person to person.

I. M. S. COMPETITIVE EXAMINATION.

The Bengalee says:—The *Indian Medical Record*, which is edited by Dr. WALLACE, urges the introduction of simultaneous examinations for the Indian Medical Service. The Government has advertised that 29 vacancies are to be competed for in the next London competitive examination. Dr. WALLACE asks why not have a competitive examination in India of the Indian Medical Service. We desire to repeat the query, and we pause for a reply. Dr. WALLACE, who ought to know, tells us that Government would get better men by holding a competitive examination here. Dr. WALLACE writes:—

Why not have a competitive examination in India for the I. M. S.? Graduates of our Indian Universities are rightly considered as well educated as medical men in England. Why not then give them an opportunity of showing their fitness for Government service by a fair and square competitive examination! In fact, why not establish a rule that henceforth competitive examinations for the I. M. S. shall be held simultaneously in London and in Calcutta? All these dreadful forebodings about not finding suitable men in England will then cease, and men of a really better stamp—for we certainly think an Indian M.B. or M.D. is far better educated than holders of British corporate licenses—both European and Indian, will enter the I.M.S. from our Indian Colleges. The solution of the problem of finding candidates in sufficient numbers for the I.M.S. lies in opening the door of competition to Indian and Anglo-Indian graduates from local Universities.

We are in cordial agreement with every word of the extract we have quoted above. Dr. WALLACE is one of the leading spirits of the Anglo-Indian Association, and if he would make common cause with us, as we hope he will, then we might almost be absolutely confident that the principle of simultaneous examination would be conceded within a measurable distance of time.

BRAVERY OF A HOSPITAL ASSISTANT.

The Baluchistan Gazette of 18th January says:—With reference to the account given in our last issue about the Loralai tragedy, it has come to our knowledge that the Hospital Assistant, MAKHAN SINGH, did not "bolt" when the fanatic came to attack the late Captain JOHNSTON, but, being himself altogether unarmed, he, after warning the deceased and begging of him to seek safety in flight, went a short way off and tried his best to maim or hinder the murderer by throwing stones at him; and it was this action of his that evidently provoked the miscreant to chase him, after he had made sure of his victim. We are very glad to be able to make public the decidedly plucky action of MAKHAN SINGH: under the peculiar circumstances attending the lamentable occurrence, we don't see what more he could possibly have done, unless he risked throwing his life away altogether. It is a most sad pity though that Captain JOHNSTON did not comply with his subordinate's entreaty, but it was his "kismet," we presume, and what happened was an inevitable pre-ordination, though Christianity forbids this doctrine.

GANGADIN VERSUS THE "INDIAN MEDICAL RECORD."

The Statesman of Calcutta has the following announcement:—

Before Mr. Justice STANLEY, at the Calcutta High Court yesterday, Baboo SATISH CHANDRA MITRA, of Messrs. T. H. WILSON and Co., Attorneys, applied on behalf of Dr. GANGADIN, of Amritsar, for the admission of a plaint against Dr. JAMES R. WALLACE, Editor of the *Indian*

Medical Record, for the recovery of Rs. 50,000 as damages for publishing a libellous letter in the *Indian Medical Record*, concerning the plaintiff, on the 12th April 1899, and another libellous article in its issue of the 18th April last, notwithstanding protest, which the plaintiff alleged were false and malicious and had injured his reputation and practice. His Lordship admitted the plaint and ordered a written statement to be filed.

A TEMPERATURE OF 120°F.

ACCORDING to the *Medical News*, ROBERT BRUCE, lately returned from service in the Ninth Infantry in the Philippines and China to Chicago, is reported to have this high temperature. Several days ago BRUCE entered the City Hospital and asked for treatment. When the house-physician took his temperature and found it to be 112°F., and the patient showing no signs of early dissolution, he was astonished. The next day it was found that the clinical thermometer had not sufficient range. Other physicians were summoned and a Government thermometer applied; the mark of 127°F. was registered, and for several days in succession BRUCE's temperature had reached this point. It is reported that BRUCE's pulse does not go up in proportion to his temperature. An explanation given as to BRUCE's condition is that a bullet, which pierced his mouth, lodged in the heat-centre of the brain.

THE PEACE OF PITY.

O brother man, fold to thy heart thy brother!

Where pity dwells, the joy of peace is there:

To worship rightly is to love each other,

Each smile a hymn, each kindly deed a prayer.

Follow with reverent steps the great example

Of those whose holy work was doing good;

So shall the wide earth seem a human temple

Each loving life a psalm of gratitude.

Then shall all shackles fall, the stormy clangour

Of wild war-music o'er the earth shall cease;

Love shall tread out the baleful fire of anger,

And in its ashes plant the tree of peace.

—WHITTIER.

BOGUS MEDICINE.

DR. J. EDWARD HENNA, of Brooklyn, says:—Antitoxine, the serio-comic of medicine, continues to receive constant attention in the journals, and promises to remain a prominent subject for future discussion. This is right, for the profession has never had a more momentous question to settle. In the interest of true medical progress, the fallacies of serum-therapy must be exposed and the mistaken views concerning statistics based on antitoxine treatment corrected; for if it is not done now, and we blindly follow the bell-wethers of bacteriology, they will lead us into a mire of mistaken conjecture, out of which it will take the profession a long time to flounder back to the firm ground of scientific truth.

HER LATE MAJESTY THE QUEEN.

THROUGHOUT India the greatest sorrow was expressed by all castes, creeds, and communities at the death of the Queen, and on Saturday prayers were offered by Hindus, Mahomedans, and Christians throughout the land. At Bombay, Calcutta, and Madras the memorial services in the Cathedrals were attended by representatives of the State. Memorials of the Queen are under discussion. At Calcutta it is proposed to carry out a scheme which His Excellency the Viceroy has proposed for the construction of a Public Hall and Museum. The Native Princes have promised liberal subscriptions.

SHORT ITEMS AND PERSONALITIES.

Dr. Jones, M. B. C. S., L. B. C. P., has been sent out by the Bengal Nagpur Railway Board as Assistant Medical Officer for this line. There is still a difficulty, it is understood, in obtaining the services of a second assistant medical officer at home, but it is to be hoped that one will be secured before the summer is round.

Major R. H. Charles, M.D., F.R.C.S.I., I.M.S. (Bengal) Professor of Surgical and Descriptive Anatomy in the Medical College, Calcutta, and *ex-officio* Surgeon to the College Hospital, is granted furlough out of India on medical certificate for eight months, with effect from the 20th February.

*Lieut.-Col. D. M. Moir, M.D., I.M.S. (Bengal), Offg. Civil Surgeon, Chittagong, is appointed to officiate as Professor of Surgical and Descriptive Anatomy in the Medical College, Calcutta, and *ex-officio* Surgeon to the College Hospital, during the absence, on furlough, on medical certificate, of Major R. H. Charles, M.D., F.R.C.S.I., I.M.S. (Bengal), or until further orders.

It is proposed to appoint sergeant cooks to superintend the training of soldier cooks under the new scheme for making British soldiers in India do their own cooking, but at present the Government has decided to limit such appointments to troops quartered in the hills.

Of the eighty-eight medical officers in civil employ who accompanied the China Expeditionary Force, twelve have returned to India, and thirty-two more will probably be sent back shortly. Leave for the Indian Medical Service may then be opened.

The establishment and early inauguration of a Central Bacteriological Institute for India is engaging the immediate attention of the Indian Medical authorities.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE INDIAN MEDICAL RECORD will, upon publication, be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary, to elucidate the text, illustrations will be provided without cost to the authors. Address the Editor, JAMES R. WALLACE, M.D., F.R.C.S., 50, PARK STREET, CALCUTTA.

NOTICE.

All members of the Indian Medical Association are kindly requested to send their names in full with their present addresses, clearly written, to the Secretary.

Members who have paid their subscriptions and who have not received the membership certificates are kindly requested to notify the same to the Secretary.

Subscribers are requested to communicate any temporary change of address not to the Office of this Journal, but to the post-office through which they are accustomed to receive their Journals.

The Indian Medical Association Provident Fund is now working. It offers a simple and safe form of Life Assurance to all medical men and women. Join at once.

The Indian Medical Record offers the following prizes:—Rs. 10 to Rs. 16 for a good Original Article; Rs. 5 to Rs. 10 for a good Clinical Report. Competitors must be subscribers to the Record.

Members of the Indian Medical Association will kindly note that while the entrance fee to the Association is fixed at Rs. 5, the annual subscription is reduced to Rs. 2.

The Indian Medical Association fights the battles of the Medical Profession as a whole, and it takes up the cause of individual members as well. Join the Association and you will not be disappointed.

Medical Appointments, Transfers, Exchanges are easily and cheaply effected through our special short advertisement page. See terms and apply at once.

News items of medical interest from all parts of the Indian Empire are asked for by the Editor for publication in the Record.

Will Members kindly notice that Seven "Calls" of one rupee each are due to the I.M.A. Provident Fund. Delay in payment means a hardship on claimants in distress.

VITAL STATISTICS OF CALCUTTA.

J. N. COOK, D.P.H., Health Officer of Calcutta.

Current Medical Literature.

MEDICINE.

Treatment of Dysphagia in Laryngeal Tuberculosis.

DR. EUGENE YONGE, of Manchester, reviews the various drugs which have been employed in the treatment of dysphagia in phthisical cases. The relief to be obtained from this painful symptom depends largely upon the selection of a suitable local anæsthetic, a substance which will be prolonged in its action, devoid of marked toxicity, not specially disagreeable to the taste, and not costly. He carefully tested a series of fifteen local anæsthetics, and while he found no ideal drug of this class applicable to every case, he found the following suitable and generally effective under various circumstances:—Cocaine, antipyrin, eucaine, orthoform, carbolic acid, guaiacol, morphia, and paramonochlorphenol. In the application of these drugs, it must be borne in mind that the absence of ulceration of the mucous surface is a contraindication to the use of orthoform guaiacol and morphia, as they fail to produce anæsthesia when the mucous membrane is intact. The author found that antipyrin maintained its anæsthetic action for a longer time than cocaine, and the quantity required was never sufficient to give rise to toxic symptoms. A mixture of cocaine and antipyrin, or of cocaine and carbolic acid, was found useful when the drug had to be used for considerable periods, the total effect of the cocaine being strengthened without a corresponding increase of that substance. Ice solutions of 5 per cent. cocaine appeared to be at least double the strength of the same solution at the ordinary temperature. Eucaine, while less toxic than cocaine, was found weaker, and was indicated when some idiosyncrasy debarred the use of cocaine. Orthoform, a comparatively new local anæsthetic (EINHORN and HEINZ, *München. med. Wochenschr.*) devoid of taste or smell, two valuable negative qualities when applied to a cleansed, laryngeal ulcer, produced, in the great majority of cases, complete relief, commencing in a few minutes after its application and lasting for several hours. It is nontoxic, and in conjunction with its prolonged action, it possesses very considerable advantages over cocaine in ulcerations of mucous surfaces. It is obtained in the form of a white crystalline powder, and its application can be made by means of a laryngeal insufflator. Guaiacol, with or without menthol in combination, had a sedative and antiseptic action in mild degrees of ulceration.

In dealing with the treatment by other methods than drugs, the author preferred rectal feeding, in exceptionally severe dysphagia, to the œsophageal tube, which caused so much distress and disturbance to the parts during its passage.—*Edin. Med. Jour.*

Toxic Factor in Diabetes Mellitus.

As the result of a clinical study, McCASKEY (*Medicine*) formulates the following conclusions: All cases of persistent glycosuria are cases of diabetes mellitus of varying grade. Diabetes mellitus is a disease of diverse origin, the unity of the clinical picture being for the most part dependent upon the glycemia and the glycosuria, which are mere incidents, although dominating factors of the disease. Phloridzin diabetes is not essentially different from clinical diabetes; it renders plausible the assumption of a chemical factor, either as a primary or as an important secondary element,

in the clinical type of the disease. Normal sugar transformation in the blood, the failure of which is responsible for the glycemia and the glycosuria, results from the presence in the blood of a chemical product, derived in man principally, if not exclusively, from the pancreas and thrown directly into the blood from the pancreatic cells, without the intervention of a duct. The direct chemical antagonism of this substance by another is no more improbable than such an antagonism of a toxin by an antitoxin. It is probable, on both clinical and experimental grounds, that certain chemical poisons, for the most part of gastro-intestinal origin, but possibly also resulting from faulty tissue metabolism, or as a perverted internal secretion from glands not necessarily ductless, either directly or indirectly antagonize, in whole or in part, the sugar-destroying substance in the blood, thus giving rise to glycemia and glycosuria, and thus, in a certain group of cases, either primarily causing, or at least exaggerating, the clinical phenomena of diabetes mellitus. If further investigation should corroborate the conclusions here provisionally set forth, it would be advisable hereafter to investigate the bacteriology of the stomach and the intestines in case of diabetes mellitus; and if evidences of virulent bacterial, protozoan, or other parasitic growth are found, these conditions should be met by suitable treatment—not with the expectation of entirely supplanting dietetic treatment, but as an important auxiliary to the latter, possibly rendering its restrictions less severe, with less resulting impairment of nutrition.

Malarial Peripheral Neuritis.

HIGHT (*Jour. Tropical Med.*) presents the results of a study of ten cases of malarial neuritis. Intermittent fever, persisting for a long time, or remittent fever with frequent exacerbations, is followed after some months by attacks of pain in the legs and knees. These pains are worse at night, and are sometimes associated with cramp of the muscles. Later the knees feel weak and give way, the limbs become painful in the daytime as well as at night, and the pain extends to the thighs, the back and the arms. Fever persists, the pain interferes with sleep, the weakness may become paralysis, cutaneous sensibility is blunted, and paresthesiæ are marked. The loss of muscular power may assume a remittent character. Hemeralopia may occur. The spleen and liver are enlarged. Deep pressure over the muscles causes pain. The tissues become flabby and may atrophy. Effusion into the joints sometimes occurs. The condition of the heart is variable; at one time it is quiet, and again it is rapid, with arrhythmia. Angina and tachycardia have been observed. Anæmia, cardiac dilatation and bemic murmurs are noted in some cases. Occasionally there is some œdema of the feet. HIGHT considers malarial peripheral neuritis to be a toxic affection of the nerves, the toxin being the product of the malarial germ. A single attack of fever rarely causes well-marked neuritis, the cumulative action of the poison on the nerves being required to bring about the pathological changes which give rise to the symptoms. The period of incubation extends on an average over eight months. Removal of the cause and efficient hygienic and medicinal treatment usually give good recovery. The diagnosis of the affection must, in most cases, be made from history. The principal points of difference are that in malarial peripheral neuritis we have marked anæmia, mild or absent heart symptoms, enlarged spleen, neuritis preceded by fever and often associated with it, the long incubation, the remittent character, the presence of plasmodium, the shuffling gait when loss of power is marked, and the readiness of cure. In beriberi affection of the heart is a regular feature, local œdema and serous effusions occur, the onset is rapid and usually attended with fever, there is no plasmodium, the gait is equine and typical, and sudden death is common. As the diseases occur in the same regions, one must think of malarial infection.—*Int. Med. Mag.*

SURGERY.**Diagnosis of Urinary Diseases.**

DR. L. GORL (*Klinisch-therapeutische Wochenschrift*) says the main considerations which lead the patient to the physician are pain, bloody or cloudy urine, or a change in the quantity of urine passed. Acute retention, pain, and a change in the appearance of the urine are the principal symptoms complained of. Hæmaturia must be the cause of a careful examination to discover its source. Clots of a long and thin character usually emanate from the kidney. Irrigation of the bladder, which is followed by a clear return flow after a few ounces have been injected, speaks in favor of renal hæmorrhage, especially if, after a clear solution has been returned, the last few drops are of pure blood. The cause of the hæmorrhage must be sought: direct or indirect injury, the effect of food or drugs, disease of the urinary apparatus, asparagus, cantharides, or turpentine may evoke a hæmaturia. If blood appears in the urine in the absence of other symptoms, it may proceed from the kidney or the bladder. In the former cases, renal carcinoma, heart disease, syphilis of the kidney, or a contracted kidney, may be at fault. In the first, the hæmorrhage is severe, is not influenced by rest, and a tumour may be felt. A heart lesion sufficient to call forth hæmaturia is usually of long duration and will be easily diagnosed. If the bleeding comes from the bladder, it is usually due to a benign or malignant growth on the anterior or posterior wall of the bladder. The blood is intimately mixed with the urine, and with the three-glass test the last portion may consist of pure blood. In benign tumours the hæmorrhage may be frequent or rare, and rest has no influence upon the character of the bleeding. In a malignant growth, such as a carcinoma with a long pedicle and many villi, hæmorrhage is frequent, while in a carcinoma infiltrating the vesical wall it is rare or entirely absent. Patients with enlarged prostates and a calculus in the bladder may show hæmaturia as their only symptom, which appears after some mild effort to disappear again after rest.

Treatment of the Initial Lesion of Syphilis.

WHEN excision or destruction by other means is not feasible, the following methods may be employed according to the location of the lesions:—

1. Within the vagina or at the portio-vaginalis. Apply mercurial ointment on cylindrical or round cotton pads to which a thread is attached to facilitate removal. In pregnant woman no pad, however small, should be introduced, but rather a suppository made as follows:—

R Ung. hydrarg. ... gr. lxxv.
Ol. theobrom. ... 3℥ss.

M. Ft. suppos. No. X. Sig. Insert in vagina. Or the lesion may be painted with one of the following solutions:—

A.
R Hydrarg. chlor. corros. ... gr. i.
Spiritus ...
Etheris sulph. ... 3℥ss.
M. Sig. External use.

B.
R Hydr. chlor. corros. ... gr. i.
Oniodii. ...
Etheris sulph. ... 3℥ss.
Ol. olive ... ℥i.

M. Sig. External use.

2. On the buccal mucous membrane, tonsils, etc. Paint with the alopholic-etheral solution of corrosive sublimate given above.

3. On the skin, or at the junction of skin and mucous membrane (lips, nose, nasal, female genitals, etc.) Cover the lesion with a piece of gray plaster, making it fit as smoothly as possible by means of incisions in its edge. Let it extend well over the border of the lesions. The renewal of the plaster should depend on the amount of secretion. The induration clears up rapidly, while ulcerations and erosions heal most satisfactorily by this method.—LANG. *XX Century Practice.*

Operative Treatment of Goitre.

J. BERRY (*Brit. Med. Jour.*) publishes some observations on the surgical treatment of goitre. While the enucleation is simple and safe, it is applicable only to localized tumors; hence skill in diagnosis is very essential. To attempt enucleation in an unsuitable case, and to abandon it for an extirpation, means considerable danger from hæmorrhage, and increased difficulty in performing extirpation. Many goitres, especially soft parenchymatous ones in young people, are curable by medical means; a still larger number, though not curable, do not cause sufficient trouble to demand operation. The main reason for operating is dyspnoea, either present or threatened; or in elderly people increase in hardness and size leading one to suspect malignant change. In a few cases operation is undertaken because of deformity. Dysphagia is rarely a prominent symptom of benign goitre. There are two types of goitre especially dangerous to life by causing sudden dyspnoea, viz, the bilateral, rapidly-growing, parenchymatous goitre in young people, in which fatal dyspnoea may intervene within a few hours, and the unilateral tumor, situated so low in the neck as to be jammed in the upper opening of the thorax, which, from displacement or sudden increase from internal hæmorrhage, may cause most grave symptoms. Unless such cases yield readily to medical treatment, surgical interference is advisable. When a small goitre is associated with marked dyspnoea, the trachea is nearly always compressed by another tumour hidden from view. In cases of marked dyspnoea there is grave danger in the use of a general anæsthetic, especially just as the tumour is being lifted from its bed. A local anæsthetic allows the patient to give intelligent assistance, prevents the venous oozing due to retching, and efficiently prevents pain. The incision giving most room is one along the anterior border of the sternomastoid. The transverse incision leaves a better scar low down in the neck, but it gives little room, and it is often necessary to cut the anterior neck muscles. In extirpation one must avoid injuring the recurrent laryngeal nerves, and a good way to do this is to isolate the lobe from surrounding tissue till near the trachea, and then to cut through the capsule and leave *in situ* the portion of capsule and a thin layer of gland which naturally cover the recurrent nerve. In enucleation one must keep a watchful eye on the hæmorrhage. The results are uniformly good.

Early Restoration of Function in Sutured Nerve.

DR. EARNEST LA PLACE reports a case of practically immediate restoration of function following suture of the ulnar nerve. The nerve had been severed for a period of sixteen months. When the ends were prepared for suturing, a distance of one and three-quarter inches intervened, but this was overcome by stretching. The ends were carefully apposed and a large number of sutures inserted. On the morning following the operation it was noticed that the boy had perfect motion of the hand. As no observation was made earlier, it is not known if motion was present immediately after the operation. Sensation in the fingers is curiously altered in that pricking at one part is felt in another. This is supposed to be due to the fact that corresponding proximal and distal ends of the fibres were not joined. The case presents points in support of the theory of the electrical nature of nerve force.

OBSTETRICS AND GYNÆCOLOGY.

Treatment of Seeming Death in the New Born.

DR. RISEMONT-DRETAIGNES said that infants born apparently dead showed one or other of the following groups of symptoms, viz.: Absence of cry, flaccid members, complete muscular relaxation, but persistent heart beat, though often feeble and at long intervals. Sometimes the cutaneous surface was bluish, purplish, or almost black, the face unmeddled, the eyes protruding and the conjunctiva suffused. This condition constituted cyanotic asphyxia. Sometimes, on the other hand, the skin was white and pale, the mucous membranes equally blanched, the heart-beats imperceptible; this state had been wrongly termed pale asphyxia. It was really syncope. Finally, in certain cases mixed forms were found, the characteristics not being sufficiently clearly marked to enable the cases to be labeled either as asphyxial or syncope. A consideration of these clinical facts would lead us to the course to be pursued in the respective cases. The asphyxial form was the most frequent in practice. It was due to the obstruction of the air passages by mucous fluids or amniotic liquid charged with meconium; whence it was necessary (1) to disengage the respiratory passages; (2) to facilitate the entrance of air into the lungs so as to re-establish or regulate the cardiac or pulmonary functions. Very frequently the mucosities occupied only the back of the mouth, consequently a simple wiping with the finger wrapped in a piece of linen sufficed to remove the obstruction and stimulate to the first inspiration. Cutaneous frictions, simple or with alcohol, ether, brandy, eau-de-cologne; hot baths, mustard baths, or baths alternately hot and cold, caused a cutaneous reaction forming most often a point of reflex departure ending in respiratory movements. On this principle was based the excitation of the mucous membrane of the nose, mouth or pharynx; also LABORDERIE'S rhythmical retraction of the tongue. Very frequently these procedures, however, were insufficient, and it became necessary to have recourse to artificial respiration. Numerous measures had been devised with the object of causing the air to inflate the lungs; mouth-to-mouth insufflation, and the methods of SYLVESTER, SCHULTZE, and BIVIER. These methods, however, fulfilled only one of the two indications mentioned above. A consideration of these indications had led the author to the insufflation method as being that of choice, and had given rise to the following data which had resulted in the construction of an instrument bearing his name: (1) The insufflation should be instrumental; (2) the apparatus should suck out the mucosities; (3) it should convey to the lungs a quantity of air. After referring to the objections to earlier instruments, the author described his own, for which he claimed the following qualities: (1) The curvature and the arrangement of the terminal portion rendered introduction easy. (2) The curve insured its retention in the respiratory tract. (3) It prevented reflux of air from the larynx. (4) It made easy the aspiration of fluids and mucous obstructing the bronchial canals. (5) Its proper insertion into the larynx, or its facile passage into the œsophagus, was easily ascertainable. (6) The rubber bulb allowed the passage into the lungs of only a quantity of air sufficient to distend them to their proper capacity, thus avoiding rupture of the pulmonary vesicles, which were very fragile at birth.

Advantages of Vaginal Section for Pelvic Suppuration and Circumscribed Hæmorrhage.

DR. E. N. LIELL (*New York Medical Record*) discusses the advantages of vaginal section over the abdominal method in dealing with cases of pelvic suppuration and hæmatocœle. He has done this operation himself in thirty-four cases, and holds that, while PEAN, JACOB, SEGUIN, and other French surgeons have removed the uterus, along with suppurating appendages, more successfully by the vaginal than the abdominal route, at least in bad cases, that a much simpler operation is in many cases sufficient, namely, vaginal incision and drainage; and also that in some cases, where the latter operation does not effect a cure, the local conditions can be so much improved that the uterus and appendages can be removed at a subsequent operation with less danger to the patient. He has in eight cases operated per vaginam, with the object of breaking down pelvic adhesions accompanied by pain, with complete success in six, the adhesions

and pain recurring in two; in the case of pelvic new growths complicated by adhesions, he has for diagnostic purposes operated on six occasions, and been able to demonstrate in two cases that the neoplasm was malignant.

As the procedure requires a sharp eye and a delicate touch, he is of opinion that the operation is only successful in experienced hands. His method is briefly as follows:—After careful asepsis, the uterus is drawn down with a volsellum, and a longitudinal or semi-circular incision made in the posterior *out-de-sac*, and the finger introduced into the incision with a boring motion; the abscess or hæmatoma is then entered with sharp-pointed scissors and the contents evacuated, care being taken to open and evacuate every pocket, should they be multiple. In nearly all cases the abdominal cavity is protected by a wall of lymph, and in very few cases has it to be opened; but this should always be done if the thoroughness of the operation demands it. "If a pus sac be the case, either tubal or ovarian, and adhesions to the uterus or rectum be present, the adhesions must often be broken up to anticipate the remote as well as the immediate good effects of the operation." The cavity should be swabbed out or irrigated and loosely packed with iodoform gauze, which should be removed in two or four days, and fresh dressings applied once or twice. If the contents have been thoroughly evacuated and good drainage established, convalescence is usually rapid. Ligatures are seldom required, forceps and torsion being usually sufficient. The THARDELENBURG position is the one adopted.

Dr. LIELL goes on to record two cases—none of pelvic abscess and another of encysted hæmatocœle—the result of ruptured ectopic gestation, in which he operated successfully by the vaginal route.—*Edin. Med. Jour.*

Post-partum Hæmorrhage.

BYRDS divides the causes of post-partum hæmorrhage into two groups: (1) Uterine atony, the bleeding in these cases arising from the uncompressed vessels in the placental area. (2) Wounds of any part of the parturient canal, without necessary uterine inertia. By far the most numerous cases belong to the first group. In the majority of cases post-partum hæmorrhage sets in without warning, though some things may put the physician on his guard, as hæmorrhage at previous confinement, rapidly succeeding pregnancies, the combination of want of exercise, and the consumption of too much food and stimulant, elderly primipara, etc. Chloroform does not promote post-partum hæmorrhage if care is taken not to deliver too rapidly. The two measures for the prevention of post-partum hæmorrhage are the proper management of the third stage of labor, and the important principle, never to deliver in the absence of pains. Two factors in the third stage of labor are the separation of the placenta and its expulsion with the membranes. Nature should be allowed to separate the placenta, and then, if she is not equal to the second task, the accoucheur may assist her in expelling the already separated placenta. In cases of secondary uterine inertia, in which labour comes to a standstill, the proper line of action is not to slip on the forceps and deliver, but to give a dose of opium; the woman will then fall asleep, after a time pains will come on again, and she will probably be delivered without any instrumental assistance. In instances of placenta prævia after bimanual version, the delivery must not be hurried, but time must be allowed for the uterine pains to come on again. When from the history or the symptoms post-partum hæmorrhage may be anticipated, precautionary measures are recommended, such as slow delivery of the fœtus, its birth being followed down by the hand on the fundus; the puncture of the membranes when the os is nearly dilated; and after it is fully dilated, the giving of two teaspoonfuls of liquid extract of ergot. If hæmorrhage does occur from an inert uterus, the first measure to be adopted is external uterine massage; second, the use of hot water, 118° F., in large quantities. The intrauterine tube should be so placed that the whole inner surface of the cavity is bathed. Salt, a teaspoonful to a pint, is preferable to creolin in the water as an antiseptic measure. Other measures are bimanual compression, packing the uterus with gauze and drawing downwards the uterus with a tractions, thus compressing the uterine arteries. When the hæmorrhage has ceased, the patient should be kept quiet, her head low, the lower part of the bed being raised to facilitate the weak circulation. Subcutaneous injections of ether and strychnine are most useful, but our main dependence is in saline transfusion.

PHYSIOLOGY, PATHOLOGY, AND BACTERIOLOGY.

Agglutinating Power of Human Blood Serum.

DR. J. DONATH (*Wiener klinische Wochenschrift*) has experimented with the blood of patients suffering from anæmia, chlorosis, leucæmia, and pernicious anæmia. The blood of a healthy person was mixed with eighty-five per cent. of a sodium-chloride solution, and was then mixed in equal quantities with the serum of the blood to be examined. A drop of this mixture was then examined in hanging drop under the microscope. Usually agglutination of the healthy blood was seen, but the results were not uniform. The blood of healthy persons, however, rarely seemed to possess the agglutinating power.

Primary Splenomegaly—Endothelial Hyperplasia of the Spleen—Two Cases in Children—Autopsy and Morphological Examination in One.

DR. DAVID BOVAIRD, Jr., says:—To the extremely scanty literature dealing with similar cases, he is fortunate in being able to add the cases of two children, sisters, similarly afflicted. The younger is living, aged six years, four years after the onset of the disease. The elder died at the age of sixteen, twenty-four hours after a splenectomy had been done, and thirteen years after the onset of the disease. The spleen in the latter case weighed twelve pounds and a half, the total weight of the child was seventy-five pounds. The form was, in general, that of the normal spleen, but very much larger. Most of the surface was yellowish-white in color like fibrous tissue, the normal color appearing upon only a small portion of the surface. Microscopically, there was nothing but the shape and arrangement of the spaces in which the endothelial cells lay, and the presence of the malpighian bodies to indicate the presence of spleen material on the slide. In the lymph nodes is also found a disappearance of the normal cells of the organ, and the development of an unusual number of endothelial cells. Other appearances seemed to demonstrate the presence of a splenic endothelioma; but when it is remembered that the process had existed for thirteen years in the case that came to autopsy, and that even then the condition of the patient was not incompatible with the prolongation of life for some years further, and also that the process was developing in a young sister at exactly the same time of life at which the disease appeared in the elder, it must be concluded that we have to do with the action of some systemic poison, rather than with a tumor. The author regards the process as a hyperplasia of the spleen, characterized by an unusual development of endothelial cells and the transformation of a considerable part of the organ into dense connective tissue. This affection, first described by GAUCHER as primary splenomegaly, or primary epithelioma of the spleen, is then a definite and distinct disease.—*Amer. Jour. of Med. Sciences.*

Structure and Genesis of Cavernoma of the Liver.

DR. VICTOR SCHMIDEN concludes from a clinical and pathological study: (1) That cavernomata of the liver do not rise from a primary connective tissue or vascular proliferation, or from congestion or primary atrophy of normal liver areas, or biliary stasis or hæmorrhage; (2) that they more probably arise from some congenital tissue transposition or defect in the development of the liver—they are therefore due to tissue deformities, and acquire their definite form from a secondary, retrogressive

change; (3) that cavernomata of the liver are not analogous to angelomata of other parts of the body—they should be called "cavernomata" or "naevi cavernosi hepatis"; (4) they are observed at all ages, even in the unborn fœtus; (5) that they are identical with cavernomata in the lower animals; (6) that they never show a tendency to become malignant.—*New York Med. Rec.*

Heredity.

M. CHANTEMESSE concludes his lengthy and learned paper on this subject. He sums up by saying that truly hereditary characteristics result from the fusion of the paternal and maternal germinative cells, or, rather, the chromatin bodies of these cells; he points out how the germinative cells, the embryo, or the fœtus, can become infected by the virus of toxins or poisons known to exist in the body. The reduction of the chromatin in the act of maturation of the germinative cells, and perhaps also the qualitative division of the microsomes of the nuclei of the cells, help in the eradication of certain definite characters of the parents, or aid in carrying them over one or two generations. The moral ego, the natural personality, which is first in the consciousness and which has been designated by metaphysicians as an irreducible unit, only represents the true state of equilibrium between the diverse hereditary forces. The ego is subject to suggestion, that is, to education, and thus by education hereditary tendencies which are latent may be reinforced, while others, even though they are prominent, may be relegated into obscurity, or, at least, into the background.

In pathological hereditary transmission, we have good instances in the birth of healthy children when a father is sober at the time of procreation, and the reverse, showing that the poisons once eliminated, the fecundating act produces healthy offspring. As to syphilis, its transmission and the prevention of its transmission by suitable treatment are well understood. As to tuberculosis, there is good reason to believe that in the great majority of instances infantile tuberculosis is acquired, and that contagion plays the most important role. While the direct hereditary influence, especially on the part of the mother, cannot be denied, it is of secondary importance.

White Blood Cells in Disease.

M. J. JOLLY regards leucocytosis in disease as a defending action of the cells against the germs of disease. When a leucocytosis persists after convalescence seems to be established, as is frequently the case in pneumonia, it is evidence that the disease has not reached its termination. The author regards it as a reaction that gives us the measure of the intensity of the disease. The seeming discrepancy of the absence of a leucocytosis in rapidly fatal intoxications can be explained by the fact that the latter are grave infections from the beginning, and run their course rapidly, while the former represent the somewhat slow extension of an anatomical lesion. The leucocytes are able to absorb not only living bacteria, but soluble substances as well, so that they probably get rid of some of the toxins elaborated during disease. Moreover, by means of their emigratory power, the white cells can pass to points which the blood cannot reach, and thus carry out their work. The origin of the antitoxins is still in dispute; whether they are derived from the leucocytes or from various organs is not definitely known.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Care of Children.

THERE is great opportunity and demand for some medical artist of the pen to paint, in glowing terms, the lot of children as it really is, and as it should be.

Even the most loving and well-meaning parents are strangely neglectful of the best interests of their little ones. Very few children are understood or properly managed. They are governed by caprice, the whims and convenience of their elders receiving first consideration. If it were not that Nature is very strong in children, as in all weak, defenceless creatures, few of them would grow up to healthy man and womanhood.

The old, selfish attitude of parents to children was that of ownership. Such an attitude makes slaves of children, and robs them of their natural rights. Such advantages as they enjoy then come under the head of privilege, indulgences for which they must pay court to parents and render unquestioning obedience.

The true view of parentage is that of a trust. A child is a little bundle of propensities and inclinations, to be trained to self-government, good and industrious habits. To this end it must have a strong and vigorous body, mental and moral discipline. Comparatively few parents try to fulfil these requirements by any regular system of management.

The great majority of children sleep when and where they can. There is no particular bedtime or nap hour. They eat irregularly anything that comes to hand. Bathing is negligently performed. If they are sensitive to cold, the cause of this sensitiveness—usually an unhealthy skin or lack of hemoglobin in the blood—is not sought and treated, but the child kept close in the hot, stuffy house, and loaded down with clothes, debarred from out-door exercise in contact with the life-giving air.

In childhood the size and vigor of the heart, the tone of nerve centres, the growth of bone, development of muscle, size and capacity of vital organs, is greatly influenced by the life led. At this time organization is imperfect, because growth and development are going on. Consequently, modification of unhealthy hereditary tendencies is easily effected by arranging for the child a mode of life calculated to stimulate all that is normal, and eliminate evidences of disease.

Children are naturally fickle and inconstant, seeking novelty, living in the present moment, shirking all that is restraining and irksome. Due allowance must be made for this to avoid strain, but still wise management can inculcate good and regular habits.

A child should have a set and an early bedtime. Congestion of the brain from insufficient sleep and unnatural excitement is at the bottom of many childish disorders. Children should not satisfy appetite all times a day on putty-like bread and glucose jellies. The mother should oversee the bathing of even large children. They cannot appreciate the necessity for cleanliness and will neglect themselves until the pores are so obstructed that a gummy mass consisting of epithelial scales, evaporated products of perspiration and oil, that Nature must start a skin disease to get rid of it.

Apathetic and indolent children, lacking in the normal play impulse, should be regularly and moderately exercised to keep them in condition. If this is not attended to, instead of developing power and resistance in the nerve centres and

a well-knit frame, they often take on huge masses of inert, feeble, flabby flesh, the tissues are clogged with waste from defective elimination, the child is always ailing, impotent, and unable to enjoy life rationally.

Teach your patients to love their children wisely, not too well. To regard them as individuals, not puppets and playthings. As they respect and intelligently care for them while ignorant and helpless, so will they reap a reward of pride and satisfaction in them when the time comes for them to go out into the world and do for themselves.—*The Med. Brief.*

Factors Leading to a Relatively High Percentage of Male Offspring.

AFTER studying more than 300 marriages with the object of discovering some of the conditions likely to give rise to a relatively high percentage of boys, Dr. GERALD S. WALTON has come to the following conclusions: (1) Do not marry the eldest daughter of a family, but rather the youngest. There is a progressive increase of boy-producing power from the eldest up to the youngest daughter. (2) Do not marry one whose age differs much from your own, and do not marry much under or over 30. (3) Do not marry a widow. (4) Do not refuse to marry a cousin, or an only daughter. He thinks that if these rules are followed, we will hear less often the complaint of paterfamilias that he has "seven daughters who prophesy" and, alas, not one son.—*Phil. Med. Jour.*

Not Liable for Trespass of Health Officer.

A THEATRICAL troupe left New Orleans for San Antonio on the last train before a quarantine was declared in Texas against New Orleans on account of yellow fever. On arrival at San Antonio, several of the members of this troupe registered at a certain hotel, the others taking quarters elsewhere in the city. In the afternoon of that day, under direction of the mayor and city physician, all were taken in charge by police, and taken to the hotel mentioned, where, without the consent and over the protest of the proprietor, they were quarantined as yellow fever suspects and detained by police officers for six days. This greatly injured the business of the hotel, and the proprietor sued the city for damages. The allegation was that the city, by and through its mayor and health officer, committed the acts complained of. It is probable, says the Court of Civil Appeals of Texas—City of Antonio vs. White—that this was a sufficient allegation that the city caused the acts to be done. It further says that the acts detailed above constituted an unwarrantable trespass, for which the mayor and health officer were probably liable. But it holds that a fact that is essential to the city's liability in cases of this kind was wanting, namely, the fact that the city was, or had made itself, a party to the trespass. It says that there was absolutely no evidence from which it could be found that the city directed, or had ratified, the proceeding, and a city, it holds, is not liable for acts of its health officers, or for malfeasances. At least it is of the opinion, it says, that, without some testimony connecting the corporation with the transaction complained of, either by showing its previous direction, or participation therein, or ratification, there was no basis for any claim of liability against it. Again, the court says, that it is of the opinion that a city could not, under the guise of exercising a strictly governmental power, evade the constitutional provision that private property is not to be appropriated for public use without just compensation; but it says that it is clear that the act must be the act of the city in such a case. A city cannot be held liable for property taken or appropriated by a trespass with which it has no connection at all. Wherefore, it holds that it was error to refuse to charge the jury in this case that the city was not liable for any wrong or trespass committed by its mayor, city physician, or police officers, and therefore to return a verdict for the city.—*Phil. Med. Jour.*

THERAPEUTICS & PHARMACOLOGY.**Extract of Suprarenal Capsules in the Treatment of Rachitis.**

W. STOLTZNER (*Jahrbuch für Kinderheilkunde*), from his studies in the use of suprarenal extract in this affection, reached the following conclusions:—

1. Suprarenal extract exercises a very favorable action upon the general state, the agitation, the perspiration, the vasomotor excitability, and especially the craniotabes of rachitic infants. All these symptoms are often considerably ameliorated within eight to fifteen days.

2. Children thus treated rapidly become able to walk, to run, and to sit upright; the softness of the bones of the thorax disappears very rapidly, and the delayed teeth begin to appear.

3. The dimensions of the fontanel, the deformity of the thorax, the costal rosary, the epiphyseal swellings, and the deformity of the limbs, are little influenced.

4. Spasm of the glottis almost always resists this treatment.

5. The amelioration of all the symptoms is especially manifest during the first eight days of treatment: later it is much less rapid.

6. If the treatment be interrupted, improvement ceases, or there is actually an aggravation of the condition, which yields when the treatment is begun anew.

7. Even in cases complicated by syphilis, enteritis, bronchitis, or broncho-pneumonia, treatment by suprarenal extract produces considerable amelioration of the rachitis.

8. In a case of grave rachitis treated by suprarenal extract, in which death was caused by the capillary bronchitis, the histological examination of the bones showed that there were no traces of osteoid tissue, and that even the periosteal osteophytes gave an almost complete reaction of calcified osseous tissue.

Arsenic in Malignant Tumors.

TRUNECKY, of Prague (*Medical Press*), has brought forward the old treatment of arsenic in malignancy under a new guise. According to his method the growth must be painted over with a solution of arsenious acid in alcohol—40 to 75 parts of the latter. The transformation is marked in a very short space of time by healthy granulations, and healing soon appears. This form of treatment, under the designation of the CZERNY TRUNECKY method, is practised in ulcerating sarcoma. When the growth is not too large, or the patient not too much debilitated, perfect recovery can be promised. He records the case of a female who had suffered from a sarcoma of the skin for twenty-four years, and after eighteen months' treatment was perfectly cured.

In following the transitions, the first change observed is an anemic condition of the superficial tissue, which cannot be distinguished from the normal beyond being bloodless; deep incisions only let out a serous fluid which oozes out slowly. Subsequently the growth gradually hardens till it is even difficult to cut, and finally necroses, lying as a hard foreign body which can be easily removed.

Mode and Rapidity of Reduction of Temperature by Quinine.

WILLIAM SYKES says:—Observations are here reported on the action of quinine as an antipyretic given in cases of high temperature, in single large doses. The temperature was closely watched for two or three hours in each case. He finds that the quinine was rapidly absorbed, the temperature began to fall in forty-nine minutes, probably in less time in the first case, and in the second and third series within twenty minutes. The size of the dose did not seem to affect the rapidity of the diffusion. In the cases experimented on, we have respectively 20, 40 and 30 grains without corresponding differences in the time of its effect. The methods of its action are obscure: (1) Destruction of pathogenic bacteria, which he thinks is negatived by the temporary nature of defervescence. (2) Neutralization of their resulting toxins, which is improbable, as they seem to bear no relation to each other. There remain only two probable methods of action, namely, on the heat-centres and on the sweat-centres. He thinks if it acted on the heat-centres the proportional decrease of temperature after exhibition of the drug would not be as irregular as it is, and the speed would not be

affected by the amount of dosage. The drug acting on the nerve-centres might be liable to produce an immediately great and regular effect on its function, which would be expected to agree in rapidity of action with the size of the dose administered. If, however, we accept the notion of its action on the sweat centres as true, an explanation of many of the difficulties is furnished. Since defervescence by diaphoresis depends on the sweating itself, and not on its action, it is obvious that the size of the dose of the drug administered, so long as it was sufficient to produce perspiration at all, would have no result on the speed of the defervescence; since slight movements in bed, by which the surface becomes chilled, would temporarily stop the diaphoresis, the stationary and even retrogressive intervals would be quite explicable. Moreover, most or all the antipyretic groups possess one quality in common when given for reduction of temperature; they produce violent diaphoresis: it also occurs in night-sweats produced by the toxins of the tubercle bacilli, which are in like manner succeeded by a normal or subnormal temperature.—*Jour. Amer. Med. Assoc.*

For Chronic Nephritis.

ACCORDING to the *Gazette hebdomadaire de médecine et de chirurgie*, M. LEMOINE recommends the following:—

R. Benzoate of Lithium	7½ grains.
Betol	8½ "
Sodium bicarbonate	3 "

M.

For one wafer. Two or three wafers may be taken daily between meals.

When the patient presents an intermittent diminution of urine, which is dark-colored and may even contain blood, LEMOINE has recourse to tannin, which he prefers to gallic acid, and which he prescribes as follows:—

R. Tannin	7½ grains.
Powdered cinchona	of each

M.

For one wafer. Two wafers daily at meal times.

If the patient cannot swallow the wafers, tannin may be given in form of a syrup, thus:—

R. Tannin	87½ grains.
Glycerin	450 "
Syrup of bitter orange peel	1,800 "

M.

From four to six tablespoonfuls daily at the beginning of meals.

This treatment must be considered for some time, but it is well to suspend treatment for one week in four. Sometimes M. LEMOINE alternates alkaline medication with tannin, administering the wafers of benzoate of lithium for a fortnight, and the tannin during the subsequent two weeks.

Correspondence.**IN DEFENCE OF CIVIL ASSISTANT SURGEONS.**

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—With reference to the remarks made by "LIEUT.-COL., I.M.S.," in his letter published in the *Record* of the 26th December 1900, I shall first deal with the amusing picture he has drawn of Civil Assistant Surgeons. What he has written is no doubt to some extent true—how far, I shall leave your readers to judge; but if he has found nothing better in his "long experience in the three presidencies," I am afraid the men he has come across are not average specimens of the service. Nobody denies that there are a good many Assistant Surgeons of the sort described, but there are others—and these are not a few—who, as all India knows, would do credit to any service or community. Indians have, of course, their defects; but where is the nation which is perfect? Personally, I am much obliged to Colonel Sahib. His exposure will undoubtedly have a salutary effect, and in gratefully acknowledging its usefulness, I hope that every Civil Assistant Surgeon will take it to heart. At the same time I would submit that, for whatever Civil Assistant Surgeons are, it is not they who are to blame. They are as they are made, for the condition of

India is at present such that very few can make themselves. The intellectual capacity of Indians, as a rule, is admittedly not inferior to that of Europeans. High authorities have testified to this. Witness how Indians acquit themselves in the most difficult examinations held in Britain, competing with Britishers on their own ground. Witness how Indians, after proper training, acquit themselves in the highest offices in all departments of Government as Chief Justices, Judges of High Courts, officers of the Indian, Civil and Medical Services, Engineers, and so on. The shortcomings mentioned are mainly due to defects in the system of education and in service rules, for which Government is responsible, and other circumstances over which they have no control. They learn their English from European teachers, and if they are unable to express themselves intelligibly (as a matter of fact only some antiquated Assistant Surgeons who under the old rules were allowed to enter the Medical Colleges with a very meagre knowledge of English are of this sort, the majority of the present officers are F. As., some are B. As., and some have a British education, and as a rule, though their English may not be scholarly, it is at any rate tolerable and certainly intelligible), it only shows that either the standard laid down by Government is still too low, or that the teachers fail to do their duties properly, or that there are defects in the system of education. If Assistant Surgeons do not know anything more than "milk, eggs and soup," and do not realise fully the importance of discipline, it only shows that they are not properly taught and trained by their European Professors and Civil Surgeons—all I. M. S. officers. If after years of education under European teachers they are "not cleanly in their attire on all occasions," and are so deplorably wanting in self-respect that they do not hesitate to associate on terms of coarse familiarity with petty subordinates and bazaar people, the inference is that the education given to them is but superficial, imparting only a smattering of language and science, and bringing no real culture with it, and that, therefore, either the teachers are incompetent, or the system is rotten. I admit that caste prejudices, social customs, etc., prove obstacles to a certain extent at the beginning; but under proper education their retarding effect is considerably minimised. Many high Indian officials are orthodox people, but the fact of their being orthodox does not in any way affect their official dealings.

Education in India (on account of its political condition) is practically in the hands of Government. In the colleges the professors give their hour's lecture and go away. They are not in touch with the students at all, and the latter learn nothing from them except a few crude facts about the subjects they are taught. There is absolutely no opportunity for learning the thousand-and-one other little things without which education cannot be complete. Western and Eastern customs and modes of thought differ widely: what is refined and dignified according to the one, is vulgar and undignified according to the other; but everything is judged by the European standard, and on account of mutual ignorance there are frequent misunderstandings. Few people can afford to go to Europe. In India there is no opportunity for rubbing shoulders with Europeans, because the majority of the latter keep Indians at arm's length, and have nothing but open contempt for everything "native." The result is that native officers are, as a rule, made inglorious people, lacking that superficial polish without which, according to European ideas, one is not civilised; but, as far as crude knowledge or morality or dignity goes, they are in no way inferior.

As regards approaching the servants of superior officers with money, offering to procure bazaar supplies, &c., the same argument again holds good. If you make people hewers of wood and drawers of water, do not blame them for hewing wood and drawing water. Colonel Sahib may be one of the few European officers who

appreciate self-respect in their Indian subordinates, but the majority of his brethren do not. Anything like self-respect in a "native" is considered preposterous. The degrading practices mentioned, and others not mentioned, are resorted to, because there is no other way. Even the lowest of the low would not like to be so slavish, but when there is no help, what is to be done? Of course the moral courage to preserve one's self-respect at any cost is lacking, because centuries of misrule have killed the very germs of independence. During pre-British administrations, sycophancy was a *sine qua non* for existence itself. "Nuzzurs" and bribes were indispensable. Under British rule reform has only been partial: much of the old system still remains. What is worse, British officers themselves are getting poisoned in Indian atmosphere. Under the intoxicating influence of princely salaries, unlimited authority, and overwhelming temptations, true British instincts get narcotised very soon, and the British officer becomes, to all intents and purposes, a little nabob—at any rate as far as his relations with his Indian subordinates go. The servants of the sahibs of to-day are "improved editions" of those of the nabobs of yore. From all the sahib's native subordinates they of course demand the usual "bakheesh," and woe to the wretch who does not pay. He must go to see the sahib according to the usual custom, and then the servants have their revenge. Even if they spare him open insults, they always behave with marked impertinence. You call in the afternoon, and you are told that the sahib does not allow "kala admees" to see him at that hour, or the servant is so busy that he does not take your card in before half an hour, or you are asked to put off your shoes outside, even though you are in English costume (Government orders only require that the shoes should be of European pattern), "as all kala admees do so." If you complain, the sahib soothes you by saying that the servant is an ignorant man, that he did not mean anything, and so on. If you say that he behaved rudely because you refused to pay the "bakheesh" he demanded, the servant, with an air of injured innocence, which even Irving would admire, will produce twenty witnesses (at one pice each) to swear that he did not demand anything, that you complained because you owed him a grudge, and the sahib piously believing that the love of truth in all "natives" is equal, literally weighs the evidence (like many of our judges), and finding the scale heavier on the servant's side, decides in his favour, or at any rate gives him the benefit of the doubt. You leave the sahib's bungalow a sadder and a wiser man, and when next day you happen to meet the servant, and he makes you a knowing salaam, you begin to realise that the path of rectitude is indeed a thorny one. How often, of how many men, and to how many men can you complain? It is the same all over.

Colonel Sahib says native officers cannot enforce discipline in managing their servants. Can European officers do it? Of course they are salaamed and "huzured" and all that, but is there any real discipline? Can they prevent dishonesty? All of them know that their chapprasies blackmail native visitors; but do they move a finger to prevent it? In the Upper Provinces the doings of Inspector-Generals' and Civil Surgeons' clerks and chapprasies are wellknown, but do Colonel Sahib's brother officers ever care to mend matters. Officers come and officers go, but all of them "do likewise." If any native officer has the courage to openly complain of the scandalous conduct of these underlings, he finds himself in trouble, because it is very difficult to prove one's statements. When by the payment of a few rupees all this unpleasantness can be avoided, and when non-payment means inevitable annoyance, the only course is to pay—"as others do."

Every Civil Assistant Surgeon learns, as soon as he enters the service, that sales, kowtowing, tips, bribes, "loans" of horses, figures in returns (never mind how

manufactured), a slavish acquiescence to the sweet will of the powers that be, and an elastic conscience, go more towards securing the good opinion of superior officers and good posts than honesty and ability, and that self-respect is altogether out of the question, if one does not wish to get into hot water. Colonel Sahib would have us believe that it is on account of the defects pointed out by him that Government does not think it fit to give Civil Surgeoncies to Assistant Surgeons and to put them in independent charge even temporarily. Why, the very men who are the worst specimens of the type depicted by him get the most responsible and coveted Assistant Surgeoncies and are nominated for Civil Surgeoncies, while "Europeanized" gentlemen, even with British degrees, are left out in the cold, because they cannot stoop to please their superiors and their underlings by taking to the degrading practices mentioned above.

In a certain province, for instance, one of the Civil Surgeons under the new rule is a man who cannot write a sentence of English correctly, who professionally is a congenital idiot, and is known, incredible as it may seem, to have actually cleaned the boots of one of his superior officers publicly in his hospital before all his subordinates! What a lesson to the other Assistant Surgeons of the province! And if this man, so wisely and justly "selected" on account of "merit," proves unfit for the position he holds, the conclusion will of course be that all "natives" are unfit for high posts. Men of this sort, in spite of their incompetence, are invariably spoken of favourably by their superior officers; while those who attempt to preserve their self-respect, though honest, hard-working and admittedly able, are almost always eyesores, and are made the victims of confidential, demi-official and private reports, even if they escape open official unpleasantness.

Colonel Sahib says that to be worthy of a Civil Surgeoncy an Assistant Surgeon "should be above influence in his public duties, caste prejudices, &c." The ideal given is of course perfect; but if an impartial view be taken, I am afraid it would be hard to find *any* officer, or even the Government itself, coming up to it. In his own service Colonel Sahib will find that many officers are "selected" for good stations, administrative appointments, &c., not really on account of special merit, but simply because the authorities are not "above influence in their public duties." Why then expect a "native" Assistant Surgeon to be a god, when sundry frailties and temptations make even celestial beings descend from their sublime heights to the humdrum level of erring mortals?

I shall pass on to the other points now:—

VISITING CHARGES.

I do not assume that every Civil Assistant Surgeon is capable of "working a district straight away." In every service there are both competent and incompetent men, and I only say that competent Civil Assistant Surgeons can safely be put in officiating independent civil medical charge. Those who have been appointed to officiate have worked satisfactorily, as can be seen from the remarks made by several Inspectors General in their annual reports. My contention is that if an officer is considered fit to do the work for 29 days in the month, he may surely be trusted to do it on the 30th day as well. If any particular Assistant Surgeon is found incompetent, or is not considered competent, a better man can easily be found to replace him. As regards European supervision, granting that it is necessary, there is the Inspector-General to exercise it. An intermediate supervising officer is superfluous. The so-called "control" of the officer in visiting charge is, as everybody knows, only nominal, and has absolutely no effect on the medical administration of the district. As I have already stated, the visiting officer simply walks round the hospital, signs a few books without looking at the pages, and sends the stereotyped inspection

note. He is not to blame for it, because his inspection must be a hurried one, as he has his own district to look after: it is the *system* which, I repeat, is faulty. In some cases even the inspection visit is not paid, though the allowance is drawn all the same! Not only does the district visited derive no practical benefit, but the one from which the visiting officer comes loses his services for four or five days in the month (more if the distance between the two is long); Government has to pay the charge and travelling allowances, and the poor Assistant Surgeon, who gets the paltry sum of Rs. 70 for doing all the work, is debarred from drawing first-class travelling allowance, because he is not "in independent" charge.

Another ground which may be put forward in favor of the present system is that the European officers of the district require a European Medical Officer. But even this is not valid, though at first sight it may appear to a certain extent reasonable, on account of the fact that in administration even the prejudices of people have to be taken into consideration. It has already been decided that Assistant Surgeons are to be appointed Civil Surgeons in 28 districts, some of the officers of which must necessarily be Europeans, and these will have to be contented with a doctor of Indian nationality. Why should not an Indian doctor be considered sufficient for a few men for a short time during the absence of the permanent Civil Surgeon of the district? If competent Assistant Surgeons are in charge, European officers will never complain.

Yours, &c.,

TOMTIT, M.B.

To be continued.

I. M. S. MEN AS PRIVATE PRACTITIONERS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—Your stirring article on the impolicy and the scandal of allowing I. M. S. doctors to practice *privately* in rivalry with independent doctors will unquestionably awaken the Government to the wrong that it has so long permitted to be publicly done. There can be no doubt that private practice by I. M. S. men must, and will, be stopped by order of the Viceroy. Why then do not these men take your friendly advice, which was given in that very fraternal editorial headed "CONSULTANTS IN INDIA: THEIR STATUS AND THEIR FEES," and drop general and family practice. Surely by having fixed daily consulting hours in their own houses, and sticking to purely consultative work, they will have quite enough to do, and enough in the way of "fees" to be satisfied with. You are right to expose this barefaced evil, and no language can be too strong, nor can any condemnation be considered ill-deserved if it serves to open the eyes of the Government to this huge system of dishonesty, for dishonesty it is. A man cannot serve two masters: he cannot serve God and mammon; even so these men cannot work fully and honestly for Government with a full day's State work to do, and yet do a full day's private practice. Every one knows how the hospital work of I. M. S. men is scamped in their mad hurry to run after outside fee cases.

It is to be hoped Lord Curzon will take the initiative in this matter, for the Surgeon-General at the head of the I. M. S. is certain not to move hand or foot to put down any wrong which men of his service are doing.

Yours, &c.,

M. D.

SUBATHU LEPER ASYLUM.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—The Subathu Leper Asylum is much in need of funds just at present, for during these winter months the income by no means is enough to cover expenses.

We have at present over one hundred Indian inmates and two Europeans—one woman and one young man.

The Asylum is situated in one of the four areas, where the proportion of lepers to the population is the largest, in India, about forty to ten thousand, and there is no other asylum near to take in the large number of lepers found in this region.

They are the first to feel want, and in increasing numbers are seeking admittance, forty-one having been admitted during 1900.

A little help at this time will be much appreciated, and enable us to meet the increased expense.

Yours, &c.,

M. B. CARLETON, M.D.,
Superintendent, Leper Asylum.

SUBATHU, PUNJAB;
5th February 1901.

"MARRIAGE AMONG LEPEERS."

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—What is the general opinion of the medical profession in India on the advisability of allowing lepers to marry—should it be allowed, or forbidden?

Yours, &c.,

M. B. CARLETON, M.D.,
Superintendent, Leper Asylum.

SUBATHU, PUNJAB;
6th February 1901.

(We trust this letter will elicit full replies from all who have experience of this deeply interesting subject.—ED., I. M. R.)

Government Medical Gazettes.

BENGAL.

Capt. E. B. Waters, I. M. S., is apptd. to be Deputy Sany. Commr., Western Bengal Circle, but will continue to be on tempy. milly. duty.

Capt. A. W. E. Cochrane, I. M. S., is apptd. to be a Resident Med. Offr., Med. Col. Hosp., but will continue to be on tempy. milly. duty.

Lieut.-Col. B. Cobb, I. M. S., Offg. Civil Surgn., Backergunge, is confirmed in that appt.

Maj. F. P. Maynard, I. M. S., Offg. Civil Surgn. of Patna, is confirmed in that appt.

Lieut.-Col. B. R. H. Whitwell, I. M. S., Civil Surgn. of Chittagong, on leave, is apptd. to be Civil Surgn. of Ranchi, vice Maj. F. P. Maynard, I. M. S., transferred.

Maj. D. M. Moir, I. M. S., Offg. Civil Surgn. of Chittagong, is confirmed in that appt.

Lieut.-Col. Hem Chunder Banerjee, I. M. S., Civil Surgn. of Backergunge, is apptd. to be Civil Surgn. of Purnea, vice Maj. D. M. Moir, I. M. S., transferred, but will continue to be on tempy. milly. duty.

BURMA.

Hosp. Asst. Anant Singh, proceeding on three months' privilege leave, relinquished ch. at the Civil Hosp., Paundge, Prome dist., on the 9th Jan. 1901.

Hosp. Asst. Shyam Kishore Dey having qualified himself for promotion, is entitled to the pay and allowances of that grade from the 16th Oct. 1900.

Hosp. Asst. Syed Abdul Ghanny relinquished ch. at the Police Hosp., Myitkyina, on the 17th Nov. 1900, and assumed ch. at the Outpost Hosp., Endawgyi, Myitkyina dist., on the 2nd Dec. 1900.

Hosp. Asst. Raj Chunder Kur, on return from leave, assumed ch. at the Gen. Hosp., Rangoon, on the 28th Dec. 1900.

Hosp. Asst. Umachandra Chakraborty, on return from leave, assumed ch. at the Police Hosp., Bhamo, on the 23rd Dec. 1900.

Hosp. Asst. Maung Lu Gale relinquished ch. of supy. duty at the Lunatic Asylum, Rangoon, on the 2nd Jan.

1901 and assumed ch. at the Civil Hosp., Paundge, Prome dist., on the 9th Jan. 1901.

Hosp. Asst. Syed Mahomed Abbas Saftar made over, and First Grade Hosp. Asst. S. Paul assumed, ch. of additional duties at the Police Hosp., Pagan, Myingyan dist., on the 10th Dec. 1900.

Hosp. Asst. V. Narasimhan Naidu assumed ch. at the Police Hosp., Falam, Chin Hills, on the 17th Dec. 1900.

Hosp. Asst. Paramanand Sukul relinquished ch. of his duties at the Civil Hosp., Falam, Chin Hills, on the 1st Dec. 1900, and assumed ch. of his duties with No. 2, Southern Chin Hills Column, on the same date.

Hosp. Asst. Daniel Paul assumed ch. of addnl. duties at the Civil Hosp., Falam, Chin Hills, on the 1st Dec. 1900, vice Hosp. Asst. Paramanand Sukul.

Hosp. Asst. Daniel Paul made over, and Hosp. Asst. V. Narasimhan Naidu assumed, ch. of addnl. duties at the Civil Hosp., Falam, Chin Hills, on the 17th Dec. 1900.

Hosp. Asst. Daniel Paul relinquished ch. at the Police Hosp., Falam, Chin Hills, on the 17th Dec. 1900, and assumed ch. of his duties with No. 2, Southern Chin Hills Column, at Minkin, on the 19th Dec. 1900.

Hosp. Asst. S. Bastian relinquished ch. at the Police Hosp., Falam, Chin Hills, on the 25th Nov. 1900 and assumed ch. of his duties with No. 1, Southern Chin Hills Column, at Haka, on the 30th Nov. 1900.

Hosp. Asst. Sawan Singh relinquished ch. at the Civil Hosp., Wundwin, Meiktila dist., on the 6th Dec. 1900 and assumed ch. of his duties with the Milly. Police Detachment proceeding from Thazi, Meiktila dist., on the 8th Dec. 1900.

Hosp. Asst. M. A. Aubaranam Pillay relinquished ch. at the Civil Hosp., Mogaung, on the 29th Nov. 1900 and assumed ch. at the Outpost Hosp., Kamaing, Myitkyina dist., on the 30th Nov. 1900.

Hosp. Asst. J. P. S. Mullins made over, and Hosp. Asst. M. A. Aubaranam Pillay assumed, ch. of addnl. duties at the Civil Hosp., Kamaing, Myitkyina dist., on the 30th Nov. 1900.

Hosp. Asst. A. C. Banerjee relinquished ch. at the Outpost Hosp., Endawgyi, Myitkyina dist., on the 2nd Dec. 1900 and assumed ch. at the Police Hosp., Mogaung, on the 5th Dec. 1900 as a supy.

Hosp. Asst. A. C. Banerjee relinquished ch. of his duties at the Police Hosp., Mogaung, Myitkyina dist., on the 9th Dec. 1900 and assumed ch. of his duties with the Mogaung Escort on the same date.

NOTICES TO CORRESPONDENTS.

M. B. Carleton, M.D. (Subathu).—With reference to his letter elsewhere, writes:—"I wish it especially for my own sake, in the hope that I may get light from many on a subject that is daily confronting me, and the answers may be helpful to others situated as I am.

A leper man sees an attractive young leper woman in the asylum and wishes to marry her. I say "No." Very soon after both leave the asylum—of course not at the same time, or for the same reason. Before long, I hear they are living in some village as man and wife. After some months, may be, both again seek admission, and, of course, not at the same time, but some weeks apart, and denying all knowledge of each other. Very soon I find that the woman is expecting her confinement. Or parties forbidden to marry here go to asylums where they are allowed to marry, and return here years afterwards as husband and wife, and may be with a child or two. Under such circumstances, separation of husband and wife cannot be insisted upon. What is to be done?"

THE BORDERLAND OF REASON.*

By G. W. BALFOUR, M.D., LL.D.,

*Consulting Physician to the Royal Infirmary, Edinburgh,
Physician-in-Ordinary to Her Majesty the Queen.*

LECTURE I.

THE famous divine, Dr. J. M. MASON, called the American PAUL, when asked to write an account of his travels, replied: "I write travels! I know not the nature of the air I breathe, the water I drink, or the land I travel over. I have lived solely for polemical divinity." Some similar idea crossed my mind when asked to lecture on *Insanity*. I have never been an inmate of an asylum for the insane, either as physician or patient, consequently my acquaintance with insanity is more or less that of an amateur, and not that of an expert. Still, in the course of many years spent in the practice of medicine, there come before us all an almost infinite variety of phases of mental activity, many of which are of considerable interest, both to the physician and the public, in their relation to true insanity. Some of these deviations from what we are pleased to call the mental norm are temporary, and others are more or less permanent in their character. They pervade every rank in life and every profession, and are found in connection with various morbid alterations of the organism, with the commencement of senile changes, chiefly those affecting the brain and at times with apparently perfect health. So common, indeed, are mental abnormalities, and so varied are their characteristics, that there is probably not one of us entirely free from some more or less insane peculiarity. So much, indeed, is this the case, that one old friend was in the habit of watching all his acquaintances for the revelation of their special characteristic, and he was never happy until he had discovered the point upon which each of his friends was—as he called it—insane; while, in their turn, his friends were in the habit of regarding this fixed idea as an incontestable proof of the insanity of their critic.

Many years ago I had a visit from one of the ablest and most learned men of his day, anxious to know how he could best arrest the pernicious habit of tight lacing in females, which had struck him as having become unusually prevalent, while he himself had suddenly become morbidly alive to the injurious results that might follow it. About a month later I had a long letter from the same gentleman, in deep distress on account of the number of very stout people he met in the streets, all of whom seemed perfectly unaware of the terrible risk they ran of having an apoplectic attack, and he was desirous of ascertaining what steps he could take to open the eyes of these unfortunates. This is a very interesting example of the manner in which senile changes may so influence a man of benevolent disposition as to cause him to take an undue and uncalled-for interest in the well-being of his fellow-men. It is not insanity, but it might very well lead to insane actions.

Fortunately, the gentleman referred to had sufficient prudence to take advice and sufficient wisdom to act upon the advice given. Upon another occasion an old lady suddenly inquired of me what was my idea of a soul? I replied that I was quite content to wait till I became a soul myself without concerning myself beforehand as to the probable characteristics of that entity. Upon this she assured me that her belief was that a soul resembled a luminous sheep's kidney floating through the air! Happening to mention this to a friend who was an adept in all spiritualistic learning, he replied that MARION CRAWFORD, the novelist, had once told him of a man who was born blind, and at the age of 20 had sight bestowed by a very simple operation. This man said he had a very definite idea of what he believed sight to be, but it was not the least like the real thing. "You and I," he added, "and the orthodox old lady, are all as incapable of forming an idea of a soul as that lad was of forming an idea of the charms of a landscape. My own idea is that a soul is a thing of the size and form of the human body, but made of something like air, quite imperceptible to our senses. This, of course, is nonsense, as it involves a dim idea of clothes—which is absurd—and also of eyes and ears; whereas a soul needs not, and has not, any eyes to see, or ears to hear, but has other and much higher means of perception. As to size, it is not omnipresent, and the old lady's kidney is as good as my human figure, which, among other inaccuracies, is based on an idea of the law of gravitation, which is inapplicable, and over which, to do the old lady justice, she had risen. Her idea of luminosity was a confusion of phenomena—the soul seems to have some power of directing forces invisible to us, especially electricity, a thing of which we can only perceive the effects; hence thought-transference, and hence the hallucinations, commonly called ghosts, which are what are called self-luminous apparitions, spirit-raps, etc., produced by action on the molecules of the brain. Hence, also, the statues made up of atoms too tenuous to be perceptible to us, but perceptible (like the stars only shown in astronomical photographs) to the higher sensitiveness of the photographic plate, whence what are called spirit-photographs, and also the more or less badly-made statues which are called materialisations, and which are so much commoner in America, where the atmosphere is so much more electrical than it is here." My old lady was a hard-headed old presbyterian, and her idea of the nature of a soul was evidently only a conceit thrown out for her own amusement and the entertainment of her friends. But you will note that it is quite otherwise with her critic. As, probably without putting much more faith in the idea than the old lady herself, he still reasons upon it as a possibility, and endeavours to point out wherein it differs from other so-called spiritualistic phenomena, and bases his objections to a soul being likened to a floating luminous kidney, not on any idea of its improbability, but on the fact that this conception is inconsistent with certain other spiritualistic phenomena which he has obviously studied with some care, and which have undoubtedly influenced his own idea of a soul. Evidently my friend would have rejected the old lady as an unsatisfactory medium, and yet her crude conception of a soul is quite within the

* The Morison Lectures for 1900. Delivered at the Royal College of Physicians of Edinburgh, and reproduced from the *Edinburgh Medical Journal* by request.

limits of sanity, while the specious and fallacious reasoning of her critic shows that on certain points he is—or rather, I am sorry to say, was—undoubtedly a denizen of borderland.

A good many years ago I came across two middle-aged ladies, who both asserted their belief that they were doomed to everlasting punishment. This belief was too much for one of these ladies. She could not stand the continual strain of such an ever-present terror, and consequently endeavoured to settle the matter definitely by attempting to put an end to herself, and was, very properly, promptly consigned to an asylum. The other took no such serious view. She played with the idea, and dangled it before her immediate relatives as an interesting horror to which she was about to be unjustly subjected. It was, however, a real belief, and led to prolonged insomnia; but she kept herself sane by widening her interests, and taking, as we might say, an intellectual view of the situation. She regarded her own unjust punishment as only one phase, and indeed, to do her justice, as a comparatively minor phase, of the gross injustice with which, in her opinion, the world was ruled. For two hours every forenoon she retired to her own room, and, as I understood, relieved her feelings by expressing in no measured terms her own idea of the state of matters. This condition lasted for years; yet during all this time this lady took her position in society. No one unaware of the facts would have noticed anything remarkable about her, while her strong sarcastic humour made her at times a most agreeable companion. This lady presented many other peculiarities. There were few clergymen of note whom she had not attempted to pose with the time-honoured problem as to the origin of evil—a problem, you may remember, to which even ROBINSON CRUSOE had no reply when FRIDAY asked him, "Why God not kill devil?" Her Bible was a remarkable object: one-half was completely expunged as entirely unworthy of belief; a large part of the remainder was shaded off as more or less worthy of further inquiry; while only a small part was left in its original clarity. Wandering all her life in the borderland, this lady has never crossed the boundary, and probably no one but her doctor and her own immediate friends had any idea of her peculiar mental condition. Some may perhaps be inclined to regard this as but an extreme case of hysteria. But there was no evidence of imperfect development of the higher nervous centres—rather the reverse—neither was there any indication of impairment of those highly complex nervous processes which form the physiological side of the moral faculties, such as underlie the phenomena of an ordinary case of hysteria. There were, indeed, not wanting signs of ordinary so-called hysteria as evinced by the presence of many more or less imaginary ailments which complicated the case. But the entire syndrome of the case, confirmed as it was by the family history, showed clearly enough that the patient was a denizen of the borderland, and nothing but watchful and loving care and a fortunate freedom from any serious bodily ailment, or any other form of impairment of nutrition, prevented her from crossing the border into the realm of true insanity. There are many such cases which, by a concatenation of fortunate circumstances, are able to be treated at home, just as

there are obstinate cases of true hysteria which are most readily cured by regarding them as insane and subjecting them to asylum treatment. For example, I was once asked to see a patient who, after a sharp attack of enteric fever, found bed so comfortable that she could not be persuaded to leave it; and as this necessitated the employment of a woman to attend upon her, she was a considerable expense to her parish. I found this woman well nourished, with healthy organs, and every muscle in her body responded normally to the stimulus of electricity. It was hopeless to attempt to treat such a patient in her own home, while no ordinary hospital could be persuaded to receive her. At some personal risk, therefore, I signed a certificate for her removal to an asylum, from which she was discharged cured in about a month.

Another patient was brought to me in a basket—this was long before the days of ambulances—and she had to be brought some distance. Her history was that she had not walked for ten years, and had not spoken for five. I daresay it has often happened to you, as it has to myself, when called upon to certify as to the mental condition of one hitherto a stranger, to be unable to get a reply to a single question, and to have nothing to notify bearing upon the case, from your own observation, beyond an obstinate taciturnity. Not one word is to be got out of the patient; while all the time of his examination he eyes his examiner with a malignant gleam of satisfaction. But, of itself, taciturnity is not insanity. I have known it regarded as a surgical disease, and treated by transfusion of blood. The operation was successful; but, unfortunately, no one could be found willing to part with his vital fluid except a foul-mouthed blacksmith, and the first word uttered was a bad one. I have not been able to discover what that word was, nor whether the bad language was permanent. Besides, a taciturnity that lasts five years is not likely to be associated with the excitable and unstable brain of a lunatic, though loss of language is common enough in association with cerebral disease, both in the insane and the sane. The patient I have referred to was obstinately taciturn, but she had no cerebral disease; she had plenty of ideas and words, too, which she poured forth copiously on paper, writing long letters, explaining her condition, and often suggesting treatment. In her own home she had been regarded as a suffering saint: and the clergymen who had been privileged to minister to her spiritual needs were in the habit of removing their shoes before entering her sacred apartment. As she was an entire stranger to me, I kept her for some time under observation before suggesting—which I did most emphatically—that so far from regarding her as a saint, I looked upon her as a modern example of demoniacal possession, adding that I had no doubt I would be able to exorcise her devil, and restore her to her proper position in society. This took some little time, no doubt; but it was so effectually done that she not only walked and talked like other people, but was ultimately happily married. I cannot say that I ever envied the husband, though they seemed always very happy together. There was in this woman an undercurrent of dry humour, which not only helped to keep her sane, but, I doubt not, made her ten years of

eclosion not only no punishment, but a perpetual source of quiet, though selfish, enjoyment.

Apart, however, from the many who live happily in the borderland, there are not a few who have done good and even great work in their day and generation, notwithstanding that, judged by an ordinary standard, they may be fairly regarded as having crossed the border, and as being quite insane on some one point or other. A well-known couplet has it—

"Great wits are sure to madness near allied,
And thin partitions do their bounds divide."

But this opinion did not originate with DRYDEN. It goes back, I believe, to the days of ARISTOTLE; and SENECA certainly puts it quite tersely and definitely when he says, "Nullum ingenium magnum absque dementia est." In my own experience, this idea has found its most apt illustration in cases of *folie circulaire*, in which the patient commences with an acute attack, and returns through a period of depression to a normal mental condition, these attacks recurring more or less frequently during life. An old friend of my own used to be subject to attacks of this character; when well, she was somewhat heavy and dull, but in her acute attacks she was a brilliant talker, and wrote most charming letters. As I had known her from childhood, we had many mutual acquaintances, and the manner in which she lit off the peculiarities of each, and detailed their private histories, was most amusing. She stuck fairly well to the truth, but sharpened the outline and heightened the colouring of each incident till the ordinary events of a commonplace life were invested with all the interest of a chapter of a sensational novel. It seems unlikely that either SENECA or DRYDEN had any thought of such a case when they penned the words I have just quoted, but rather that they referred to those many great men in all ages whose beliefs and whose actions have fairly entitled them to be reckoned among the number of the insane. Idiots, demented, and madmen are undoubtedly insane; but they have no monopoly of mental unsoundness, and the world at large has never recognised how much of its history and progress has been due to those who, judged by modern standards, may be regarded as truly insane.

Among all the great and noble characters of antiquity, there is none so pre-eminent as SOCRATES. A sculptor of no mean powers, the creator of many statues which have been much admired for the taste and elegance of their execution; a soldier of great activity and courage, two at least of his scholars—ALCIBIADES and XENOPHON—owed their lives to his martial prowess; and possessed of talents greater and more powerful than almost ever fall to the lot of man, he is best known as the founder of moral science. His whole life was spent in doing good, in constantly endeavouring to induce his fellow-men to curb their vicious propensities and desires, and to cultivate and improve their virtues. Both by precept and example, he commended to his fellow-men that dauntless serenity of mind which nothing could disturb or alarm. He divested the study of philosophy of its asperities and technicalities; and the dignity with which he applauded all things just and beneficial gave an

importance to his opinions which the purity of his character and the simplicity of his doctrines rendered doubly impressive. To enable men to form just opinions, and to make them happy, was the main object of his life; and he was little solicitous about his own fame, or any credit he might deserve as the founder of a new philosophy. His life was spent in promoting the best interests of his fellow-men; and it was laid down at their bidding, but not before he had with great firmness and energy disproved the false and unjust accusations which had been brought against him. Throughout all history there is no record of a nobler character than that of SOCRATES; and yet, judged by modern standards, it is impossible to avoid the conclusion that he was insane. SOCRATES had, as he believed, a genius or demon, whose voice he heard and whose advice he permitted to direct his actions. "By the favour of heaven," says SOCRATES in the pages of PLATO, "there has been bestowed upon me from my earliest youth the most marvellous gift of a spiritual voice—a voice which, when heard, often causes me to abandon what I designed to do, and never advises me wrongly. If any of my friends tells me of any project he has in hand, and the voice is heard, it is a sure sign that this design is not approved of, and ought to be given up." SOCRATES gives several striking examples of the nature of this warning, and of the results, according as the warning was attended to by his friends or the reverse. From these and many similar passages, it is evident that SOCRATES actually heard a voice that spoke to him and advised him according to his needs. He specially designates it as a voice, the voice, as it seemed to him, of a being other than himself which spoke to him, and not merely his own thoughts or his own conscience to which he had given the semblance of articulate speech. It seems in truth to have been a hallucination of the sense of hearing which SOCRATES regarded as the voice of a deity, and looked upon as his own special prerogative. He placed implicit confidence in the warnings conveyed by it, and nothing in this world could induce him to do what his demon had forbidden to be done.

Nor was this all. SOCRATES was also subject to fits of ecstasy or trance, which attacked him at sundry times without warning. Sometimes these seizures attacked him when conversing with his friends, and on one memorable occasion when among his fellow-soldiers at the siege of Potidea. Upon that occasion he passed a whole day and night standing in the open field in a state of ecstasy, regardless of the astonishment which his conduct excited among his fellow-soldiers, who camped about him all night to watch the end of this singular proceeding. SOCRATES did not recover consciousness till sunrise on the second morning, when, after a profound obeisance to that luminary, he stalked slowly and silently to his tent.

There is no reason to doubt that SOCRATES believed he heard a voice exterior to himself which he himself felt sure was that of a god or demon (genius). This voice distinctly uttered articulate words into his ear, and the communications so received were frequent, and were implicitly trusted. SOCRATES did not merely think he

heard a voice—that would be a hallucination of his reason. He actually heard a voice speaking loudly and distinctly, yet no mouth approached his ear and no vibrations reached his tympanum—this is to have a morbid hallucination of the organ of hearing. No one can believe that SOCRATES actually had communications from a supernatural being, and the only alternatives are either that he was an impostor who made an empty boast of his divine communications, or that he had a true hallucination to this effect. But SOCRATES was a man of the strictest probity, who devoted his whole life to the discharge of what he believed to be his duty, even though this led to his accepting the poisonous cup of hemlock juice. He was a man of noble thoughts and great power of will, and steadily pursued the object of his mission to an advanced period of life. No imposture could have been carried on so long without the mask being dropped now and then, and no one could have practised deceit for so long without being once and again discovered. Moreover, it is truth alone that gives force to speech, and it is impossible that SOCRATES could have exerted the powerful influence on his fellow-men which he did, if he had been a miserable impostor, playing upon the credulity of those around him. We are therefore forced to believe that SOCRATES actually heard the voice he supposed was sent for his guidance and direction. But as nothing really spoke—as no voice was sent—he must have been the dupe of a delusion that caused him to give wisdom and a body to words that sounded in his ear alone. This is to have a positive hallucination—a hallucination which in our day might have brought him under the cognisance of the Commissioners in Lunacy. And if we couple the supernatural voice with the remarkable fits of ecstasy or trance to which SOCRATES was subject, there is every reason to believe that a modern psychologist would have but little difficulty in assigning the affection from which SOCRATES suffered its proper place in psychological nosology. Even my own limited experience enables me to form what I think would prove to be a fairly accurate idea of the term he would apply; but inasmuch as this has never yet been formally propounded by any one, I refrain from mentioning it, lest my inexperience should land me in the category of those who rush in “where angels fear to tread.”

I have the less difficulty in making such a statement, because modern psychology has made great advances, and the diagnostic characteristics of many forms of mental aberration have been so accurately defined that, from the records of a fairly accurate biography, it is possible to form a retrospective yet correct estimate of the mental condition of its subject. Such an application of psychology to history is often sufficient to light up some of its most obscure passages, and to explain the origin of motives which, in a seemingly incomprehensible manner, have powerfully influenced mankind in various directions. It cannot be denied that insanity has exercised a most important influence upon the destinies of nations, as well as on their progress in philosophy, science, and literature. The presence of mental aberration is apt to be overlooked when it happens to coincide with the prevalent opinions or thought of the age, but, more closely regarded, it will often be found

associated with the greatest and most powerful talents, and to dominate the wills and thoughts of all with whom it comes in contact, not merely at the time, but for many generations. Of this, SOCRATES, the reformer of Greek philosophy, is a most striking example; and to take another from my own profession, I may mention VAN HELMONT, one of the greatest medical philosophers of the Middle Ages, whose name I dare say few of you have ever heard, yet the influence of whose thoughts was so great, that more than two hundred years after his death (in 1866), the Royal Academy of Medicine of Belgium offered a prize of 1,200 francs for the best estimate of VAN HELMONT'S influence on the progress of medicine down to modern times. VAN HELMONT was born in 1576, and, having devoted his life to study, he became, as one of his biographers has termed him, the Faust of the seventeenth century. He studied philosophy, law, and theology, but found them all but a weariness of the flesh. He refused the degree of Master of Arts on account of his own ignorance; also a Canonship, as he did not feel equal to the duties of such a position. At last, in despair, he prayed to be made what the Lord thought best, and was told in a dream that the Angel RAPHAEL would be always with him to guide and instruct him. After this he studied astrology, chemistry, and materia medica, beginning with Dioscorides and the herbalists, finally devoting thirty years to the study of all the medical words then extant. A thorough theosophist, he again prayed to be instructed, and took counsel with his own soul, which appeared to him as a small luminous body in human form. This wonderful being, to which his reason was but a subordinate handmaiden, as he was meditating on the horrible uncertainty of medicine, lifted up its right eyebrow and exhibited a wondrous eye, not composed of coats and humours like a human eye, but a brilliant globe like the planet Venus, which showed him not only his own deep ignorance, but also the error and darkness that prevailed around. Aghast at his own presumption in writing on a subject of which he really knew so little, VAN HELMONT was about to burn all he had written, when his soul opened its left eye, and showed that such an act would be a piece of the grossest selfishness, and he was warned and admonished in a dream that knowledge like a tree covered with blossom and fruits was the gift of the Almighty, and to be employed for the benefit of mankind. Relying on the help of the Angel RAPHAEL, and the advice and counsel of his own soul, he studied all the works on medicine then extant—some 600 in number—and devoted ten years to travel and the study of science and medicine in every available country. He was a most accomplished chemist, and among other discoveries in this science he first propounded the nature and properties of gases, and particularly those of carbonic acid gas. He was no great practitioner, yet his fame was so great that various potentates sought to allure him to their dominions. He emancipated himself from all the schools and prevalent theories of his day, and was the founder of a new and vitalistic theory of medicine, which modified, no doubt, and, with some changes in its terminology, has pervaded all medical science, and has proved its guiding principle down to the present day. VAN HELMONT'S Archeus was the *vis inertia*

of HALLER, the *vis medicatrix nature* of CULLEN, and has its analogue in the essential characteristics of the organic antitoxines of our own day. While as VAN HELMONT sometimes regarded and spoke of his Archeus as a ferment, from this point of view it naturally gets linked on to the views and theories of PASTEUR, and assimilated to the organic antitoxines on their chemical or materialistic side. From this we see that this Archeus of VAN HELMONT has a great future before it still, as the organic antitoxines have before them an as yet scarcely realised function to fulfil in the cure and still more in the prevention of disease. Perhaps the most learned man of his day, and one who cared for learning less for its own sake than for the good it enabled him to do, VAN HELMONT was an enthusiast, a fanatic, and above all things, a theosophist, but he was more—he was a dreamer of dreams, a companion of astrologers, of sorcerers, and of witches. He was full of delusions, and the victim of many hallucinations. He had many interviews with the Angel RAPHAEL, and his own soul, as a separate entity, was his teacher and instructor. From this point of view there are, I daresay, many inmates of asylums not half so insane. I know of one very intelligent and agreeable man, who had to be incarcerated solely because he avowed his determination to kill his wife on account of her High Church and Ritualistic proclivities. VAN HELMONT lived a long and honoured life, left many discoveries behind him, and, in spite of his insanity, his commanding genius has been so impressed upon the theory of medicine, that its influence is never likely to be lost. As the follies and vices of one generation are apt to result in evil to the succeeding one, as the evils of drunkenness are not always so evident in the drunkard himself as they afterwards become in the enfeebled nervous systems of his children, so it is interesting to note that VAN HELMONT's son was an exaggerated specimen of his father's peculiarities, without inheriting his remarkable brain-power.

It is a trite and often true saying, that *quem Deus vult perdere prius dementit*, but the converse is equally true, that when Providence has any great work to be done, He makes some one a little mad about it. Even in our own day we have had some remarkable examples of both truisms; and in past times, perhaps, the most remarkable instance of that madness which precedes and accompanies the accomplishment of great and notable deeds is to be found in the history of JOAN OF ARC. In the beginning of the fifteenth century the whole of France, north of the Loire, was in the hands of the English; in 1430, HENRY VI was crowned at Paris king of France and England, and everything pointed to the speedy expulsion of the DAUPHIN, son of CHARLES VI of France, from the southern part of his dominions, of which he still had a precarious hold, when suddenly the victorious advance of the English was checked; they were ultimately driven from all their French possessions, except the city of Calais, and CHARLES VII was crowned king of France, all by the instrumentality of a peasant girl of 18 years of age. This is probably one of the most remarkable episodes in history, and the agency by which it was brought about was even more remarkable than the episode itself, because the whole incident belongs so entirely to the unexpected that it seems quite inexplicable

on ordinary principles. It was not an example of the compassion natural to the sex leading to unparalleled self-sacrifice for the protection of the unfortunate, as in the case of FLORA MACDONALD. It was an unheard-of and almost incredible instance of a girl, still in her teens, casting aside the trammels of sex, and leading to victory a beaten and discouraged army under the influence of what she believed to be divine guidance. Here was an age, no doubt, in which such a belief was more than usually possible, and JOAN's history is but another example of the presence of insanity being overlooked, because its manifestations happen to coincide with the prevalent ideas of the day. JOAN OF ARC was born in a small village in the north-west of France; she was taught to sew and spin, but not to read or write, and was distinguished for her modesty, simplicity, and piety. It so happened that the village in which JOAN was born took the side of the French, while a neighbouring village espoused that of the Burgundians, the allies of the English. The boys of the two villages had daily conflicts, so that from her earliest childhood the opposing battle-cries of France and England were for ever sounding in JOAN's ears; while an imaginative child, such as she was, could not fail to be impressed by the talk of her elders as to the down-trodden state of her beloved France, and the feelings thus roused could not fail to be still more strongly excited by her friends and companions having, on one occasion, temporarily to flee for their lives from their homes, not getting back for four days. It was small wonder, then, that the voice, which in her 13th year urged her to be modest and pious, gradually became more insistent and more definite as to what she was to do. Wherever she went the voices followed her, and mingled specially with the church bells' chiming. JOAN's hallucinations were not of hearing alone; she never heard a voice without also seeing a bright light—both came on the right side. When walking in the woods, JOAN heard voices around her, and when listening to the ringing of bells, the voices of saints and angels mingled with their chimes. Gradually her delusions extended to other senses; she saw the Angel MICHAEL, ST. CATHERINE, and ST. MARGARET; these saints she embraced and kissed, and found they had a pleasant odour. Gradually, too, the voice which at first spoke only of modesty and piety urged her to hitherto undreamt of acts. "Go," it said, "daughter of God, go, go, go; and I shall be with you to help you—go." This injunction was but indefinite, but it showed how the heaven was working, and ere long the voice became more insistent and more definite. "JOAN," it said, "the King of Heaven has selected you for the succour of France and the help and protection of King CHARLES." As the tide of war rolled on, the prolonged siege of Orleans kept all France in a state of continual excitement, and JOAN's voice became more insistent and more definite in its instructions. "Go," it said, "to ROBERT of Baudricourt, the Commandant at Vaucouleurs, he will help you." At first ROBERT of Baudricourt was incredulous as to her mission and amused at her simplicity. But the people took her part, bought her a horse, and provided her with male attire. At last her insistence prevailed, and ROBERT of Baudricourt sent her with an escort to the Dauphin at

Chinon. We can imagine the astonishment of the Dauphin when this girl of 18, dressed as a man, came before him with the statement that she had a mission from Heaven to relieve Orleans, and to crown him king of France. The Dauphin naturally hesitated; he kept JOAN about the court for some weeks, and had her examined by theologians, and her conduct watched by all the hangers-on about the court. But JOAN stood the test. At court she remained the same simple-minded, devout, and modest girl she had always been. From the priests of St. CATHERINE of Fierbois she received a sword marked with five crosses on the blade, which, she said, her voices had revealed to her was hidden underground near the high altar. Clad in complete armour, mounted on a white horse, with a white banner carried before her, on which were painted the likeness of Our Lady with two angels, each having a lily in her hand, JOAN entered Orleans at the head of an armed array of noblemen and men of war. The English feared her as a witch, and did not dare to oppose her; the citizens of Orleans received her as if she were the Deity Himself. Three of the English forts were shortly carried by assault, and within ten days the siege was raised, and the enemy in full retreat. It must have been a most remarkable sight to see this simple maid not only leading her troops to battle and ordering their whole array as if she had been all her life a soldier, but also taking the lead at the council table, and pitting her miraculous voices against the opinions of such able and experienced Generals as DUNCIS, the Bastard of Orleans, ALENCON, and LA HIRE. It is unnecessary to pursue the subject further. Taught by her miraculous voices, and aided by her own unquestionable genius, this girl of 18 dropped the garb of a simple village maid, and, clad in all the panoply of war, sat at the head of the council table or led her troops to battle as if she had been to the manner born. CHARLES VII was crowned king of France at Rheims, and JOAN wished to return to her village home, deeming her mission accomplished. At the king's request, JOAN consented to remain with the army; but apparently her heavenly directions ceased. She no longer heard unearthly voices, and she began to have fearful forebodings. In no long time she was taken prisoner by the Burgundians and sold to the English, and after trial and nearly a year's imprisonment, JOAN was burned at the stake as a sorceress and a heretic. It seems that in prison her spiritual voices returned, but they no longer urged her to doughty deeds or spoke of triumph and victory. The voices promised that she would be set free from prison, but they never mentioned how, and urged her to "take everything cheerfully," promising that after her martyrdom she would "come at last to the kingdom of heaven."

Her compatriots never spoke of JOAN as insane, and her history but affords another example of how readily insanity gets overlooked when its manifestations happen to coincide with the spirit of the age. But there is no doubt as to her delusions and hallucinations. To the last she maintained the reality of her revelations, and she died a martyr to her convictions.

The story of JOAN OF ARC is a most remarkable one; it affords a very striking example of the influence of

delusions upon an excitable temperament, of the fact that hallucinations are often associated with an indomitable will and with considerable strength of intellect, and it is a remarkable instance of the manner in which insanity has moulded history and influenced the fate of nations.

But perhaps the most notable example of the influence of insane delusions upon the history of the world is to be found in the story of MOHAMMED and of the religion which he founded—a religion which, at the present day, numbers among its votaries over 160 millions, or about one-ninth of the entire population of the world. MOHAMMED has been stigmatised as a prophet of deceit, and the religion which he founded has been derided as a suggestion of the devil, and though insanity has been occasionally spoken of in connection with MOHAMMED, yet it has never been received as an adequate explanation of his conduct or procedure; and one of those who have most recently written of him—one, too, who by his training and studies ought to be a most competent judge—distinctly says: "I cannot call him insane." Nevertheless I venture to differ from this opinion, and to say that MOHAMMED was even more unmistakably insane than JOAN OF ARC, and that the religion which he founded was the product of his insanity, modified by his own commanding intellect and by the spirit of the age in which he lived. MOHAMMED was born towards the end of the seventh century, at a time when, under the influence of Judaism on the one hand, and of Christianity on the other, the ancient pagan creeds were fast crumbling away. Paganism in all its forms may indeed be said by that time to have ceased to be a living faith, and was only clung to by the people as a sacred inheritance from their forefathers. Already there were many prophets in the field who proclaimed the futility of the ancient pagan creeds, and who taught the unity of God, the religion of ABRAHAM. Some sought to combine the more noble forms of paganism, such as the worship of the heavenly bodies, with this purer doctrine; while others turned aside to Judaism on the one hand, or to Christianity on the other. MOHAMMED was a true child of his time, influenced more or less unconsciously by the many contradictory views which all his life had been seething around him. He was 40 years of age before he took up the role of a prophet himself, and sought to find a new faith which should take the place of idolatry, and yet be distinct from either Judaism or Christianity, and in this his delusions and hallucinations undoubtedly aided him, if they did not, as is probable, primarily start him on his quest for a new religion.

Ordinary epileptics are not generally very interesting subjects; so far from being associated with any manifestation of genius, the intellect, under the influence of repeated attacks, tends to become rapidly debased.

But there are some epileptics who retain all their faculties apparently unimpaired, notwithstanding the persistence of epileptic attacks from early youth, and in some cases in spite of the occurrence of repeated maniacal attacks. For we know that an epileptic attack is occasionally replaced by an outburst of mania, which may last for some time, or be as sudden, as violent, and as evanescent as a fit of epilepsy itself.

While there are many whose faculties remain unimpaired by the obdurance of epilepsy, there are few who, at all events during its early stages, develop a peculiar aptitude for certain forms of learning or of work, though commonly this special intellectual sharpening too long disappears under the degrading influence of the disease. I myself was well acquainted with one lad who developed quite a genius for the solution of arithmetical problems, and also for making patterns for fretwork, in neither of which was he any ways proficient in his pre-epileptic days, and they were gradually lost in the progress of the disease. The morbid religiosity of epileptics forms a well-known element in the syndrome of the disease. It is the one form of disease in which exaltation of the religious sentiments is most frequently observed, associated with a marked laxity of morals. But apart from this morbid religiosity, we often find epilepsy associated with hallucinations of various kinds, affecting sometimes the sight alone, and sometimes the hearing alone, and sometimes both sight and hearing. You all, no doubt, remember Dr. JAMES GREGORY'S patient, in whom the epileptic aura was replaced by the figure of a little old woman in a red cloak, who seemed to walk up to him and strike him down with her crutch. About the middle of this century, the late Professor ALISON began to suffer from severe epileptic attacks. These seizures were followed by delirium of a very violent and acutely maniacal character, but during the fits he seemed lost in the contemplation of some blessed vision; he thought he was in Elysium, and he believed he heard the praises of the heavenly host, and amongst them he heard the voices of many long-lost friends whom he recognised and with whom he conversed; so that it was a matter of regret to him when he recovered consciousness of the external world. These remarkable attacks were thus accompanied by hallucinations of sight and hearing, of the reality of which ALISON at the time entertained no doubt, and they were followed by acute maniacal attacks, during which he was undoubtedly, though only temporarily, insane.

Now we learn from the history of MOHAMMED that he was epileptic from childhood; as in other epileptics, the fits were often followed by periods of prolonged unconsciousness, during which he had hallucinations of sight and hearing. He saw the Angel GABRIEL, who conversed with him, and who, he believed, revealed to him sentence by sentence the contents of his sacred book, the Koran, which contains regulations for both the civil and religious life of his followers, while even the pleasures promised them in the next world were evidently dictated by the impulses so distinctive of epileptic religiosity. There can be little doubt that MOHAMMED was insane, and as ALISON'S insanity bore the impress of a highly educated and deeply religious Christian, so that of MOHAMMED is distinctly stamped with the spirit of the age in which he lived, when all around him there were prophets and leaders of men seeking to turn the hearts of mankind from the old polytheism which was crumbling away, to a purer monotheistic religion. MOHAMMED'S wife and some of his relations, to whom he had revealed his earlier hallucinations, encouraged him in the belief that he was favoured of Heaven, and set apart as the prophet of a new religion, which, though modelled

on the monotheistic doctrines of the age, was distinctly modified by his own powerful and practical intellect. More than 1200 years have passed away since the death of MOHAMMED, yet the religion which he founded is still a living faith to more than one-ninth of the population of the world; and if we acknowledge that MOHAMMED was insane—and I do not see how we can avoid this conclusion—then we must also acknowledge that the prevalence of Mohammedanism affords one of the most remarkable instances of the manner in which insanity has modified the kingdoms of this world and has influenced the progress of humanity.

Thus far I have endeavoured by selected examples to show how much mankind has been indebted for its progress in philosophy and science to those who—if not actually insane—have certainly been dwellers in the borderland of insanity, while a similar influence has had most important results in the domains both of arms and of religion. If we turn now to the realm of letters, we shall also find that some of the noblest works in literature have been produced by those who have all their lives dwelt in the borderland, while some of the noblest conceptions of the human mind have been scrawled by a madman on the walls of a madhouse. In seeking for examples illustrative of the influence of this peculiar phase of mentality upon human progress as revealed in literature, we are met by a perfect *embarras de richesses*—more so, perhaps, than in any other department of human knowledge; probably because all literature is the product of individualisation, and no one can individualise his thoughts without at the same time exaggerating their peculiarities. I have been more struck with this in the literature of psychology than in that of any other subject, and I am inclined to attribute this marked character in psychological literature to the influence of environment, so well known as one of the most important agents in modifying the development both of mind and body. I shall not, however, pursue the subject farther in this direction, nor shall I be tempted by any modern illustrations, but shall at once carry you back a couple of hundred years to JONATHAN SWIFT, Dean of St. Patrick's Cathedral, Dublin, the greatest of English satirists and the most original writer of his day. It is surely a splendid triumph of genius that "GULLIVER'S Travels," written as satires to excite and gratify the political feelings of men, should 200 years later still survive and be loved as the most delightful of fairy tales by the children of their descendants. SWIFT'S "Tale of a Tub" was one of the most powerful religious satires of the eighteenth or of any other century. His "Drapier Letters" caused the Government of the day to give up their purpose of flooding Ireland with the copper coinage of an English patentee, and created so great an excitement in Ireland as to raise the unknown author to the pinnacle of fame. Two rewards of £300 each were offered to any one who would unmask the author of these letters; but the secret was well kept, and not a traitor could be found to sell him. Not to be prolix, I will only mention one more of SWIFT'S writings, his "Modest Proposal," in which he suggests that the distress of the poorer Irish might be relieved by employing their children as food for the rich, and which is a perfect masterpiece of satirical irony.

SWIFT died at the age of 78, and the last three years of his life were passed in almost total silence and in the charge of keepers. One of his biographers suggests that the cerebral disease of which SWIFT died, and which ended in complete dementia, must have lasted for fifty-five years, and there is some reason to think that this estimate is not far wrong. SWIFT was deaf, and was subject to attacks of giddiness, and a comparatively recent writer has claimed that the cerebral degeneration which was ultimately fatal was an extension from the peripheral disease of his ear. I am not aware that modern pathology would sanction any such assumption. SWIFT himself had a clearer conception of the nature of his disease, when, pointing to the withered boughs of a decaying elm, he said to his companion, Dr. YOUNG—"Like that, I shall die at the top." His disease was no doubt peripheral; but it affected the periphery of the brain, and did not originate in any other organ. All his life SWIFT was liable to severe—almost maniacal—paroxysms of temper, which doubtless were early indications of that degeneration which ultimately ended in complete dementia. This tragic close, to which SWIFT so pathetically alluded, seems to have shadowed all his life; he was subject to fits of maniacal excitement, alternated by periods of intense mental depression, estrangement from his friends, increasing giddiness, and a tottering gait, gradual loss of vision, loss of memory for words, and ultimately total silence. I have not touched upon SWIFT'S relations with STELLA and with VANESSA; the mystery in which these relations are involved is indubitably connected with SWIFT'S mental malady; but its elucidation necessitates too minute and searching an inquiry to be entered upon now. It is enough for my present purpose if I have succeeded in showing that one of the greatest literary geniuses of our country was all his life a denizen of the borderland, and had formally crossed the border years before he ceased to be mortal.

SWIFT was a poet, but rather mediocre; it is as a satirist that he will live. On the other hand, WILLIAM COWPER was a great prose writer, and his letters are amongst the most charming compositions in the English language; but it is as a poet that his name will descend to generations yet unborn. For who can imagine a time when the infant mind will cease to be amused by the adventures of "JOHN GILPIN," or the patriotism of the schoolboy fail to be roused by the words of the dying Boadicea—

"Regions Cæsar never new
My posterity shall sway;
Where his eagles never flew,
None invincible as they?"

poems not of the very highest or most philosophic stamp, but which appeal at once to the sense of humour and of patriotism innate in every human breast. Simple and natural, COWPER'S poems were a great change from the stilted language and far-fetched imagery of his predecessors, and it was these very qualities which won their way into the hearts of all when they were first published, and has kept them afloat upon the stream of time for more than one hundred years. It is not the fashion to read COWPER now-a-days, but quotations from his poems are more in use than from any other author

except SHAKESPEARE. His hymns have exercised a greater influence upon evangelical religious life than those of any other hymn-writer save JOHN WESLEY; and probably more tears have been shed over his lines, "On the receipt of my Mother's Portrait," than over any other poem in the English language. COWPER'S longer and more didactic poems are full of graphic pictures of simple country life and habits as they existed last century, coupled with moral and religious reflections of the highest character, seasoned with the Attic salt of fervid satire. Last century COWPER was regarded as one of the greatest poets of the day, and no one can deny that he occupies even yet a very high place in English literature, and yet all his life COWPER was a dweller in the borderland.

A delicate, sensitive boy, COWPER had the misfortune to lose his mother when only a child of six; his school life was embittered by the tyranny of his class-fellows, and a deeper melancholy was impressed upon his timid diffidence. At 21, COWPER was called to the Bar, but never practised. He was ultimately offered the office of Clerk of the Journals of the House of Lords. But he shrank from the needful examination at the Bar of the House as well as from the publicity of the office. At this time his misery was so great that he thrice attempted suicide, and had to be placed in seclusion for about a couple of years. Throughout the most of his after-life COWPER enjoyed—thanks to the kind attention and cheering influences of many friends—a measure of tranquil happiness, though at the age of 40 he had a second period of five years of the deepest melancholy, from which he again recovered. It was after this recovery that COWPER published the first volume of his poems; it is known that many of his hymns and minor pieces were written when he was in a state of the deepest dejection, and it is highly probable that many of his longer pieces were being thought out, if not actually composed, when he was still in confinement. On the death of his kind friend, Mrs. URWIN, COWPER fell into a state of the most profound melancholy, and though he kept his ailment at bay by continuing his translation of HOMER, and otherwise employing his poetical talents, he died seven years later, protesting at the last that he was plunged in "unutterable despair." A very striking example of how much the world owes in its literature to those whom it stigmatises as insane. I need not multiply examples, they are easy to be found, and as common as blackberries. I shall only give one more, and that chiefly for the sake of the remarkable contrast between the nobility of the thoughts expressed and the circumstances under which they were produced.

CHRISTOPHER SMART, well known as a translator of HOSACK and as the winner of the Seatonian prize at Cambridge, during five successive years, was a Fellow of Pembroke College, Cambridge, but closed this connection by marrying. This necessitated his removal to London, where he became a friend of GARRICK and of JOHNSON, but with all his talents and all his exertions he failed to keep poverty from the door. The tendency to depression, present throughout his whole career, was aggravated by disappointment and debt, and SMART was first placed within the rules of King's Bench, and ultimately in an asylum, where he died.

On the wall of his asylum, SMART, with a bit of charcoal, scrawled the following noble thoughts, forming part of his "Song of David":—

"He sang of God, the mighty Source
Of all things, the stupendous Force
On which all strength depends:
From whose right arm, beneath whose eye
All period, power, and enterprise
Commences, reigns, and ends."

The world, the clustering spheres He made,
The glorious light, the soothing shade,
Dale, campaign, grove, and hill,
The multitudinous abyss,
Where Secrecy remains in bliss,
And Wisdom hides her skill.
'Tell them I AM,' Jehovah said
To Moses; whilst earth heard in dread,
And smitten to the heart,
At once above, beneath, around,
All Nature, without voice or sound
Replied, 'O Lord, Thou art!'

I think I have given you a sufficient number of examples to show that in every department of human progress—in philosophy, science, arts and literature—insanity has exercised a most important influence, and we are now entitled to ask, has this remarkable effect been produced by the insanity, or has the apparent coincidence been purely accidental?

Now this is too interesting and in many ways too important a subject to be rashly dogmatized upon, and there is much to be said from both points of view. First, we cannot forget what ABERCROMBIE has said:—

"A remarkable peculiarity, in many cases of insanity, is a great activity of mind and rapidity of conception—a tendency to seize rapidly upon incidental or partial relations of things, and often a fertility of imagination, which changes the character of the mind, sometimes without remarkably distorting it. The memory in such cases is entire, and even appears more ready than in health; and old associations are called up with a rapidity quite unknown to the individual in his sound state of mind. A gentleman, mentioned by Dr. WILLIS, who was liable to periodic attacks of insanity, said that he expected the paroxysms with impatience, because he enjoyed during them a high degree of pleasure. 'Everything appeared easy to me. No obstacles presented themselves, either in theory or practice. My memory acquired, all of a sudden, singular degree of perfection. Long passages of Latin authors occurred to my mind. In general, I have great difficulty in finding rhythmical terminations, but then I could write verse with as great facility as prose.' 'I have often,' says PINEL, 'stopped at the chamber door of a literary gentleman, who during his paroxysms appears to soar above the mediocrity of intellect that was familiar to him, solely to admire his newly acquired powers of eloquence. He declaimed upon the subject of the revolution with all the force, the dignity, and the purity of language that this very interesting subject could admit of. At other times he was a man of very ordinary abilities.' And, secondly, we must not forget that as mental influence alone is of itself sufficient to give rise to stigmata and to other morbid affections, especially in a certain class of patients, so the general prevalence of any special excitement, such as the English invasion of France in the days of JOAN OF ARC, or the religious transition of the days of MOHAMMED, may give rise to special forms of cerebral excitement quite apart from the presence of insanity, but which may also be variously modified by the co-existence of special delusions.

A MIRROR OF PRACTICE.

A SECOND SUCCESSFUL CASE OF CÆSAREAN HYSTERECTOMY.*

By COLIN CAMPBELL, L.R.C.P.L., M.B.C.S., ENG.,
Saddleworth.

History of Patient.—On July 25th, 1900, I was called about 1 P.M. to see a woman in labour in a gipsy van. The labour had commenced about "daybreak."

The woman, aged 24, was about 4 feet in height. Her mother said she had been "deformed all her life." It was her second pregnancy, the previous one having been terminated by craniotomy at Halifax "about" a year before.

Examination revealed a pseudo-malecostean rachitic pelvis, also that the child was living. I therefore advised its immediate removal by abdominal section, and that the patient should be at once removed to a room, as in the van the bed was only approachable on one side, and one could not stand nearly erect. (2) That if they declined removal and operation, that she should be immediately taken to an infirmary, Oldham and Ashton being respectively five and six miles distant.

After much delay the former alternative was chosen, and at 5 P.M. I was informed that a good Samaritan had taken her in, making a bedroom of her "parlour," which opened directly on the road. I saw the patient again at 6 P.M. with my partner, Dr. DAVID PRICE, equipped for any emergency.

Selection of Operation.—In such a case, supposing the child to be living, the alternatives before the practitioner are:—

- (1) Killing the child by the brutal "operation" of craniotomy.
- (2) Ordinary CÆSAREAN section.
- (3) PORRO's operation.
- (4) Symphysiotomy.

(1) As the child was still living, we rejected the first alternative. Personally, I can see little difference between plunging a perforator into the brain of a living fetus *in utero* and plunging it into the brain of a child hidden under the bed clothes.

(2) Except in the able hands of MURDOCH CAMERON or LEOPOLD, CÆSAREAN section has still a terribly high mortality, and successful cases leave the patient liable to further pregnancies—and "sections!" This is not ideal.

(4) As to the merits or demerits of SINGULTIAN operation, we did not enter, rejecting it at once in favour of—

(3) A modified PORRO's operation, in which both child and uterus are removed, and further pregnancies (and operations) effectually prevented. In PORRO's operation the procedure is, shortly, as follows:—

To cut down first through the linea alba, next through the anterior wall of the uterus, "avoiding, if possible, the placenta," next the fetus is removed. "Hæmorrhage from the uterine wound may be checked by grasping the

* Read at a meeting of the Lancashire and Cheshire Branch of the British Medical Association.

cut edges with pressure forceps, having large transverse blades.....The uterus is drawn through the abdominal wall, the intestines being kept back by an assistant, and covered with large flat sponges..... and then a KÖEBERLE'S *serre-nœud* is passed round the lower part of the uterus." This is tightened, and the stump fixed in the abdominal incision by means of transverse pins.

The modification of this operation adopted by the late Mr. LAWSON TAIT appears to me to be of more practical importance than the original design. He so simplified the procedure as to render it practicable, at a moment's notice, by any surgeon who has at hand a knife, a piece of stout rubber tubing, and two knitting needles; by his method it is also a bloodless operation.

In PORRO'S operation an assistant (as well as an anaesthetist) is required to check the hæmorrhage and work the sponges; large flat sponges should be at hand, also a supply of transverse-bladed forceps, and that somewhat cumbersome instrument, the *serre-nœud*. The control of the hæmorrhage from both sides of the uterine incision, as well as from a possibly wounded placenta, suggests considerable difficulty.

Mr. TAIT ligatured the uterus before opening it. This was done by passing a loop of strong rubber tubing over the fundus, then drawing the tubing down to the lower part, and tightening it as an ESMARCH'S bandage. Thus performed, neither assistants nor unusual instruments are required.

In anticipating a similar, and also successful, operation, my friend, Dr. JOHN SUTCLIFFE (now of Cheadle Royal) suggested that the loop of tubing which was intended to pass over the fundus would be more manageable if stiffened, and this was found to be so; for whilst it was impossible to get the limp tubing over the fundus through an incision which extended upwards only as far as the umbilicus, it was easily done when a piece of gutta-percha-covered wire was first passed through.

The operation was performed under the most unfavourable conditions; the room was small, dark, and crowded with furniture; no nurse or handy woman was available, only a neighbour who had once "seen an operation." The patient had become irritable and restless, her pains were continuous, pulse 128, temperature 100°. My partner's whole time was occupied in looking after the anaesthesia. The abdominal incision was four inches in length downwards from the umbilicus; through this the tube, stiffened as described, was passed over the fundus, and then drawn down as low as possible, the wire drawn out, and the tube tightened and knotted. Then the uterus was opened without hæmorrhage, and the left hand introduced to push aside the placenta and find a foot. This was found with some difficulty, and a living infant delivered. Next the uterus with placenta enclosed were drawn out, coils of gauze being introduced to prevent fistulae following, and the only assistance that was required by the operator was the "neighbours" to hold up the uterus whilst it was being transfixed with guarded pins and amputated. Four sutures closed the abdominal wound, the "stump" filling quite one-third of its length.

After History.—On the third day the temperature reached 102°; then, after a dose of Epsom salts, it became normal. The stump came away on August 21st. I exhibit it to show the effect of the elastic ligature. I regret I am unable to show the patient and infant.

The woman was walking about by the fifth week, and they then left the district. I have had the help of the police and the "King of the Gipsies," but the scent was lost at Blackburn.

In conclusion, I would express the hope that two successes so easily obtained may (in the words of Dr. HERMAN) help "to relegate craniotomy, the induction of premature labour, and symphysiotomy, alike to the past."

USEFUL HEARING OBTAINED IN A DEAF MUTE, AGED 19 YEARS.

By J. LOCKHART GIBSON, M.D., EDIN., M.R.C.S., Eng.,

Brisbane, Q.

THIS case, a girl now of twenty years, illustrates the importance of not concluding too readily that a deaf mute, with some hints that hearing has not been absolutely destroyed without hope of repair, should be left severely alone. It also illustrates a point regarding lymphoid hypertrophies in the nasopharynx, upon which I have insisted in more than one paper, viz., that comparatively small hypertrophies in the fossæ of Rosenmüller are apt to do more harm to the hearing than much larger ones in the general nasopharyngeal space.

MARION SHAW, aged 19 years, was brought to me from the Brisbane Blind, Deaf and Dumb Institute on June 3rd, 1899.

History on that date.—She has been an inmate of the institution for six years. Her parents say that she could hear as a baby, and had begun to talk a little before contracting measles at the age of 18 months. She had not talked since until taught lip-reading. The teacher says that her hearing helps a little in teaching, when an ear-trumpet is used, or sounds are spoken loudly just behind the ear. For all practical purposes, she is deaf and dumb. Breathes heavily, if a cold.

Examination.—Membranes very opaque and indrawn. Fork, well by bones if very loudly sounded, heard in each ear, by air conduction. Nasopharynx, found a dense band of hypertrophy in each Rosenmüller, and that between these bands and a central small roof mass of adenoids there was a sulcus in each case.

June 29th, 1899.—Removed, under cocaine, a dense piece of hypertrophy from right Rosenmüller, and a somewhat larger piece from left Rosenmüller. Two solid fillets of LOWENBERG'S forceps from the roof of the nasopharynx.

July 10th.—Mother says, hearing things about the house and dogs barking, which she had not heard previously.

July 17th.—Removed another small piece from left Rosenmüller, and four or five small pieces from the nasopharyngeal roof.

July 27th.—Calls all the family by name, hears dogs barking, knocks at the door, and rain pattering upon

the roof. In my room hears her own name quite plainly at a few inches from her right ear, and numbers at two feet.

Since removing her "adenoids," I have regularly politerised her ears. She has had comparatively little teaching since, and not much training to the ears; but, at her own home, her mother and sister tell me that she hears a great deal and can always be called even from one room to another (wooden house). Of course she had learnt lip-reading, and any words said to test her hearing must be said behind her back, or with the mouth hidden. Her articulation is still very imperfect—sufficiently so, indeed, to prove to you that she has been a deaf mute. The number of words that she has been taught by sound is small. She has to learn her sound vocabulary like a child. Still, you will notice that she hears enough for us to hope, as her teacher does, that she will in time be able to depend more and more upon her ears, and less and less upon lip-reading in conversation. Her own name and accustomed words, such as "Good-bye!" and numbers, she hears at long distances, several yards, and repeats at once. Short sentences, such as "How are you?" and "Are you quite well?" she hears at a few feet, when spoken distinctly, in an ordinary voice, and repeats them.

A second somewhat similar case, and under treatment at present, a girl of 15 years, has obtained some hearing, but not so much as MARION SHAW.

ERYTHEMATOUS RASH DUE TO BORIC ACID.

By HENRY HANDFORD, M.D., F.R.C.P.,

Physician to the General Hospital, Nottingham.

MUCH attention is being devoted at the present time to the effects of boric or boracic acid, and the opinions expressed by capable observers vary exceedingly. The following case, therefore, may be of some value, although the fact that the ingestion of boric acid is liable to produce a skin rash is already well known:—

On April 18th, G.B., aged 47, a coal-miner of Clay Cross, was admitted into the Nottingham General Hospital under my care with dilatation of the stomach. He had suffered from dyspeptic symptoms for three years, but vomiting only began fourteen months before admission. He had lost flesh and strength considerably, and been unable to work for some time. For three months and a half before admission, the stomach had been washed out frequently, but without much benefit.

A non-malignant stricture of the pylorus was diagnosed, but before advising surgical treatment, it was determined to give a further trial to washing out the stomach with some suitable antiseptic, as the previous washing out had been mainly carried out by the patient himself, although under medical advice. There are not a great number of efficient antiseptics which can safely be used in large amount for this purpose; and boric acid lotion 1 in 80 was selected as the most suitable. The stomach would hold $4\frac{1}{2}$ pints of fluid before the patient felt uncomfortably distended; but much less than this quantity was used for each washing out. The stomach was first emptied of its contents by a tube as far as possible. Then about $2\frac{1}{2}$ pints of warm boric acid solution were introduced, allowed to remain two or three minutes, and returned by the siphon action of the tube. This was repeated two or three times until the fluid returned nearly clear, and the stomach left as nearly empty as is possible under these conditions.

The washing out was continued from April 19th to 25th, on which day an erythematous rash appeared upon the face and back. The skin was reddened, swollen, and thickened in broad patches, and there was much itching.

Plain water was substituted for boric acid solution for washing out the stomach, and the rash disappeared in two days. From April 27th to April 30th boric acid solution of a strength of 1 in 200 was used. On the morning of April 29th there was a little redness on the elbows, and by April 30th the erythema had spread to the back of the neck, eyelids, lower part of the back, and thighs. The use of boric acid was stopped, and the rash entirely disappeared by the morning of May 3rd.

The patient stated that he had not before suffered from a similar or, indeed, any rash, although the stomach had been washed out frequently for three months and a half previously, but without the employment of boric acid. He was kept under observation for another week without the recurrence of the erythema, and then transferred to the surgical wards on May 10th.

On the following day the abdomen was opened by my surgical colleague, Mr. ANDERSON. The pylorus was found to be greatly thickened and somewhat fixed by adhesions, but there was no definite tumour. The operation of pyloroplasty was performed and the stricture completely relieved. The patient made an uninterrupted recovery and rapidly regained weight. He is now (November 15th, 1900) in good health and working regularly as a miner.

TRAUMATIC URETHRAL STRICTURE: INCONTINENCE: URETHROTOMY: CURE.

By T. M. SHAH, L.M.,

Medical Officer, Junagadh State Hospital.

13th April 1900.—PREMI M., male, aged 30, was admitted with incontinence of urine. It was dropping away involuntarily, the clothes were soiled, the bladder was empty, that is, there was no overflowing.

In the middle of penis there was a nodular induration. The urethra was impervious to the smallest catheter at this point.

Patient received a kick from a horse at his penis two months ago, much swelling and inflammation resulted, and blood was passed with urine, and incontinence and stricture were the consequences.

15th.—Chloroform was administered, longitudinal incision was made on the under surface of penis at the seat of induration, stricture divided and urethra was laid open. Catheter No. 8 was then passed through meatus into bladder. Then the urethral margins were brought together by horse-hair sutures, and next sutures were applied to skin. Iodoform lint and adhesive strapping applied.

17th.—Urine voided by catheter, few drops through wound, swelling of penis owing to tightness of dressing.

23rd.—Sutures gave way, sides gaping, urine passed through wound and also through catheter.

24th.—Silver catheter removed: india-rubber catheter kept in.

27th.—Wound contracting and healing: all urine per catheter.

30th.—Wound healing: all urine through urethral meatus: urine passed voluntarily.

2nd May.—Wound healed: no incontinence: urine per urethra: none through wound.

Remarks.—Traumatic stricture of urethra was thus cured by plastic operation of external urethrotomy, but why there was incontinence, and why it ceased after operation, are puzzles which I would like to be solved by your numerous experienced and eminent readers.

overlooked by the Sanitary Commissioner entirely. He accounts for the great difference between European troops and native troops as follows :—

"The proportion of cases returned as simple continued fever is much lower in the native army than in the European; perhaps because the native soldier is not liable to enteric fever, even in a mild form; because he is not so easily affected by the heat; because his ingestion habits are more regular; and because the tendency in the native army is to call mild fevers ague."

Considering the extent to which simple continued fever is returned amongst native prisoners, it is obvious that all these reasons are wide of the mark, except the last, which simply amounts to saying that slackness in diagnosis is the cause of so few cases being returned in the native army.

The causes to which simple continued fever is ascribed are sun, heat, over-exertion, want of acclimatisation, especially when combined; chill, exposure, constipation, errors in diet and drink. Some of the cases were suspected to be enteric fever, or malarial fever, or influenza, or Malta fever, or some yet undifferentiated fever; and the application of the serum test is said at Rawal Pindi to have led to the smallness of the number of cases returned as simple continued fever.

All this is very unsatisfactory; many of the causes given are not applicable to native prisoners who, as we have seen, suffer to a considerable extent. The tendency in many places at the present day, notably in the United States, is to assume that all cases of simple continued fever are nothing more than mild cases of enteric; the large number of cases amongst prisoners seems to disprove this—in fact absolutely disproves it—if any reliance can be placed on the figures and in the belief that the native is immune to even mild enteric.

The question is obviously in a most unsatisfactory state, and the Sanitary Commissioner's way of dealing with it shows how little importance is attached to it, and how little hope there is of any correct solution in the near future.

CHRONIC ARSENICAL POISONING.

The recognition of chronic arsenical poisoning, even by specially-trained observers, is proverbially difficult. The toxic symptoms, which are subject to many permutations and combinations, have been usefully divided by P. BROUARDEL and G. POUCHET into four stages—the stage of digestive disturbance, the stage of eruptions and of laryngeal and bronchial catarrh, that of sensory disturbances, and that of paralysis. In the first stage there is most characteristically lassitude and *malaise*, anorexia and nausea, gastric uneasiness, and sometimes diarrhoea. In the second stage there is evidence of catarrh of the conjunctiva, of the nasal mucous membrane, of the larynx and bronchi, with various skin eruptions and pigmentation. The third stage is characterised by numbness, tingling, formication, and other paræsthesiæ of the extremities, by spontaneous pain with frequent headache and extreme tenderness of the limbs, to even the slightest pressure as of the bedclothes, and anaesthesia. In the fourth stage there is first weakness, and later actual

paralysis of the extensor muscles of the toes, the so-called dorsiflexors of the ankles, and the extensor muscles of the wrist and fingers, giving double foot-drop and double wrist-drop. The paralysis, although usually limited to the extremities, may in severe cases invade the trunk.

ARSENICAL PARALYSIS.

The occurrence of paralysis from arsenical poisoning is said to have been first described in the thirteenth century by PIERRE D'ALBANO. In 1561 AMBROISE PARE described paralysis of all the extremities *duetto arsenic*; it was recorded also by BOERHAAVE, and subsequently by a multitude of physicians. Of 120 cases of arsenical poisoning collected in 1881 by GOUVERNEUR, paralysis of a peripheral type occurred in over one-half. G. BROUARDEL, in the *Archives de Médecine Expérimentale* for 1896, has tabulated the principal facts of some 78 cases of arsenical paralysis occurring after 1852. In 33 it followed repeated doses for arsenic, and in 45 one large dose. Three of the former, which may be taken as typical, are as follow :—

Case I.—On January 13th, 1893, Dr. A. G. BARR, Professor of Medicine in the Yorkshire College, showed a boy, aged 12, almost totally disabled by paralysis due to arsenic, before the Leeds and West Riding Medical-Chirurgical Society. During about eight weeks he had been given arsenic in the Leeds Infirmary for chorea in gradually increasing doses, the maximum dose reached being 18 minims of FOWLER'S solution. During this time he had occasional attacks of vomiting, and although the knee-jerks were absent when he was discharged cured of his chorea, arsenical poisoning was not apparently suspected. A month later he was readmitted with dropped feet and hands, and paralysis of the muscles of the trunk as well as of the limbs. There was wasting of the muscles, anaesthesia, tenderness of the nerve trunks, and loss of all tendon reflexes.

Case II.—On October 17th, 1893, Dr. T. C. RAILTON, then President of the Manchester Clinical Society, showed a case of arsenical paralysis in a girl aged 10, who had been treated with FOWLER'S solution for chorea of three months' standing. She received five-minim doses three times a day for three days, and ten-minim doses three times a day for fifteen days; in all about $13\frac{1}{2}$ drachms were taken equivalent to $6\frac{1}{2}$ grs. of arsenious acid. At the end of that time the chorea had disappeared, but during the course she had shown symptoms of stomach derangement. Two days after the discontinuance of the medicine desquamation of the skin was observed, and ten days later she became unable to walk alone. She had pains in the arms and legs, and the legs were in particular very tender. She complained of pins and needles in the feet, and was unable to button her clothes. There was double drop-foot, the paralysed muscles showed the reaction of degeneration, the knee-jerks were absent, and the urine was slightly albuminous. Dr. RAILTON at the same time stated that he had treated nine other children for chorea with 15-minim doses of FOWLER'S solution, three for the space of one week, and six for two weeks: of these seven had vomiting, one diarrhoea, three herpes zoster, two erythema, and one peripheral neuritis,

but not so severely as the first patient. In all the chorea was cured at the end of the treatment, but he had come to the conclusion that 15 minims was too large a dose if continued for more than a week.

Case III.—Dr. WILLIAM OSLER, on October 27th, 1892, began to treat a man suffering from HODGKIN'S disease with FOWLER'S solution, the dose of which was gradually increased, until after two weeks it had reached 15 minims three times a day, beyond which it was not raised. By the end of November the skin was bronzed in places. On December 19th the drug was stopped for eight days. The pigmentation increased, and there was occasional diarrhoea. By the middle of January the muscles of the legs were very tender, and the man walked stiffly. At the end of January he walked with much difficulty; the muscles of the legs were flabby and the knee-jerks had disappeared. On February 2nd a modified reaction of degeneration was observed in the paralysed muscles. During seventy-five days the patient had taken 33 drachms 18 minims of the solution, equivalent to 16½ grs. of arsenious acid.

The following case is not included in BROUARDEL'S tables, but it is quoted as a typical one of more recent date:—

Case IV.—Dr. W. S. COLMAN showed before the Clinical Society of London, on January 14th, 1898, a girl, aged 12, who had been treated with FOWLER'S solution for chorea. On September 23rd, 1897, when she had been suffering from chorea for six days, she became an in-patient. From September 27th to October 28th, with the exception of six days when the administration of the drug was suspended on account of gastric disturbance, she took 15 minims of FOWLER'S solution three times a day. She left the hospital cured of the chorea and apparently quite well. On November 10th her legs tingled and felt weak. On November 17th there was distinct ankle-drop. In December she was admitted into the National Hospital, Queen Square, with almost complete paralysis below the knees, with well-marked reaction of degeneration, weakness of the extensor muscles in the forearms, and diminished faradic reaction. There was no anaesthesia, but the leg muscles were tender, and there was well-marked arsenical pigmentation of the neck and groins. Dr. COLMAN remarked that the case showed that these somewhat heroic doses of arsenic, which had been so highly vaunted in the treatment of chorea, were not without serious dangers. Several instances of similar paralysis had come under his notice, and in one recovery had not taken place.

PATHOLOGICAL ANATOMY OF ARSENICAL PARALYSIS.

The paralysis due to arsenic may occur at an interval, usually measured by weeks, after the ingestion of a single large dose, but the presence in the blood of a minute quantity for a long time is more apt to produce it. As in the case of lead, it is uncertain whether the toxic substance in the blood acts primarily on the peripheral nerves or on the cells in the anterior horns of the spinal cord, or whether it acts simultaneously on both. That arsenical poisoning does produce degenerative changes in nerve cells has been demonstrated experimentally by NISSEL, LUGARO, SCHAFFER, MARINESCO, and others, and

that it does produce destructive changes in the nerves, has been experimentally demonstrated by JASCHKE and ALEXANDER, while SKLARET and others have found both central and peripheral changes in animals poisoned with arsenic. ALEXANDER administered arsenic to 50 rabbits; six of these developed paralysis, and in three there were demonstrable lesions of the nerves. Paralysis of the hind limbs was produced by the arsenical poisoning of guinea-pigs by BROUARDEL and THORNTON in many instances. The doses used were medium (about 0.7 mg. per 100 grams of body weight), and were given at an interval of two days. Paralysis occurred in some in about nine days. LEYDEN has reported the results of the *post-mortem* examination of two cases of arsenical paralysis, both showing multiple neuritis. BRILICKI and RYBALKEN, on the other hand, have reported necropsies on two cases which showed changes in the cord in addition to neuritis. Although the evidence is as yet insufficient to determine whether the cell or the nerve fibre first shows definite microscopical changes, it is probable that the whole neuron, cell as well as its axis cylinder process forming the nerve, is extremely sensitive to the toxic influence of arsenic. But experiment seems to have shown that the nervous system of man is more susceptible to its action than that of any of the animals ordinarily used in research.

THE QUESTION OF DOSE.

The amount of arsenic required to produce toxic symptoms seems to be governed by many factors, such as the age of the person taking it, the form in which it is taken, the condition of the stomach when it is taken by the mouth, the co-operation of other toxic agents and individual peculiarities grouped under the heading idiosyncrasy. When death has occurred from a single dose, it has been very difficult to estimate how much of the quantity taken has been in operation, because much may have been vomited, and much of the very insoluble solid arsenious acid has probably been passed unchanged *per rectum*. The smallest fatal dose hitherto recorded is two grs. of arsenious acid. But it is a matter of everyday observation that slight toxic symptoms, such as watering of the eyes and a silvery tongue, are produced by the medicinal use of FOWLER'S solution in medium doses.

TOXICITY OF ARSENIC.

Perhaps one of the most marked cases of the toxic activity of arsenic is that of a patient who developed definite symptoms after taking 45 minims of FOWLER'S solution, less than half a grain of arsenious acid, in five days. The activity of arsenic solution is much greater than in the solid form, and yet, while the maximum dose mentioned in the *British Pharmacopoeia* of the solid arsenic is $\frac{1}{15}$ gr., the maximum dose of the more active solution is 8 minims, about $\frac{1}{15}$ gr.

A case is recorded of an infant who died from the effects of arsenic that it had received through its mother's milk, who herself showed toxic symptoms, but recovered.

The amount of arsenic necessary to produce toxic symptoms, when inhaled into the lungs as spray or vapour, appears to be extremely small. Death has occurred in several instances from the application of arsenical preparations to inflamed surfaces, as to a cancerous breast

or to an inflamed tooth pulp, and it is probable that a condition of catarrh of the stomach rather facilitates the absorption of arsenic.

TOLERATION.

That a degree of toleration to the drug may be attained appears to be fairly well established. This is described particularly among the operatives in the Salzburg arsenic works, and in the case of the arsenic eaters in Styria; but is said that many of the latter succumb in their attempt to establish the habit. It is stated that a small community in Cumberland habitually drink a water containing 1 gr. of arsenic to the gallon, and are healthy.

Among other evidence showing that in conjunction with another neuritic poison, such as alcohol, the drug is more virulent, may be instanced the epidemic of arsenical poisoning in 1888 in Hyeres, when more than 400 persons were affected from drinking wine contaminated with arsenic; the cases of paralysis among them were investigated by PIERRE MARIE.

ELIMINATION.

In this connection a consideration of the rapidity of the elimination of the drug is of importance. It is often stated that it does not accumulate; but this is only partially true, because, although it rapidly begins to be eliminated, the complete elimination is a matter of time. In the Hyeres epidemic arsenic was recognised in the urine forty days after the drug had been taken. From observations on animals LUDWIG gives three weeks as the time needed for complete elimination, and GUBLER six weeks; the latter also states that after it has ceased it may reappear if potassium iodide be given.

IDIOSYNCRASY.

As a rule, it has been found that after middle life its untoward effects are more easily developed; but a case corresponding with that recorded by Dr. BROWN, of Bacup, of an infant who developed symptoms from mere traces of the drug obtained by sips of infected beer, was recorded in one of the French epidemics (Havre). The variations of the individual in regard to susceptibility are almost, if not quite, as marked in the case of arsenic as in that of lead, and—as seen, for example, in the case of epileptics to whom it has been given in small doses mainly to prevent bromism—one patient may develop a bronzed pigmentation from doses taken by another with no obvious toxic effect.

THE MANCHESTER EPIDEMIC.

In regard to the present epidemic of neuritis in the Manchester district, the almost invariable condition is that the affected persons drank beer, but not more than the average person, say, London. Many of the beer drinkers of Manchester have contracted a disease which absolutely corresponds with chronic arsenical poisoning, but the beer drinkers in London have not. Arsenic has been found in the beer sold to the patients in Manchester, and has been recovered from their urine. The beer sold in London has been found to be quite free from arsenic. As a correspondent has pointed out, it has been stated long before the present epidemic that, according to observations made in the past at the Manchester Royal Infirmary, multiple neuritis is often caused by beer, and this is certainly not the experience in London.

COMMENTS AND NEWS.

LIVING BEYOND A CENTURY.

MR. WILLIAM KINNEAR, in the columns of an American contemporary, discusses the question of "old age" in a pleasant, chatty style. We give a rapid review. It is pointed out that, whether heredity has anything to do with longevity or not, it seemed to be shown by statistics that centenarians, and such as lived to an extreme age, usually inherited this quality from the mother, and her mother, rather than from the male line of ancestors. The longer the time of growth the longer the life seemed to be the rule with man and all other animal bodies. Athletes were not usually long lived. Nervous energy and a determined will were no fair equivalents for a naturally feeble physique, and many young men of this class, by competing with those much superior in physical endurance and strength, ruined themselves for life. It was the heart, the lungs and the arteries that suffered most in this strain, and not the muscles. Overtaxing a body not intended by nature for such contests showed its bad results in old age. Old age always showed itself first in the arteries: if these were soft and compressible, there was little deterioration; if without elasticity and thickened, nutritive conditions were being interfered with in the various tissues. Natural genius, which had been highly cultivated and refined by a certain form of education, developed a morbid sort of excess with much irritability. Such usually did not live long. After people had reached extreme old age, the question frequently arose as to what should be done with them. JAMES PAYN, the novelist, seemed to think long life a dreadful bore. Dr. AINSLIE HALLIS insisted that old age in the present time came later, and youth and manhood had a better race: middle life had shifted to 50 instead of 35. Formerly the longest lived were the labourers and those of the poor ignorant class who spent much time in the open air. Now even the poets lived long. The 'clergy' live the longest, and physicians, as a rule, the shortest. People of one hundred years and over show generally little or no trace of gout and rheumatic affections, and were not so prone to disease as younger people, who only reached middle life. Special maladies were rare among them. They merely wasted away and died painlessly. Climate had undoubtedly much to do with long life. Regions exempt from sudden changes of temperature, and where one could live much in the open air, were best for those who desired to live long. All reports of centenarians fully support the belief that the ability to take and enjoy exercise out in the clear, clean, fresh air contributed largely to long life. Vegetarianism had not yet produced many centenarians: these all eat meat occasionally. The brain affections of centenarians and the recoveries from them was one of the most remarkable of their peculiarities. In an aged person the brain was progressively shrinking, and the interspace between it and the skull caused by the shrinkage was being filled by fluid effusions in the subarachnoid or pia mater tissue, and there might be temporary irregularities and imperfections in this compensating adjustment of the pressure of fluid on the surface and of the blood circulation in the interior which would account for cerebral attacks, and also for the recoveries from them. As students of longevity, it was not necessary to insist on a strict fruit and vegetable diet. Statistics demonstrated emphatically that women exceeded men as long lived. Cheerful and contented people always lived longer than the irritable and fretful. Sound centenarians, however, could not be made out of bad material. Old age was curtailed of many pleasures.

but it also escaped many annoyances to which younger people were subject. If a proper use of early years had been cultivated, and prodigal and riotous living not indulged in, a wholesome age could be looked forward to. Official tables seemed to prove that long-lived families were more likely to produce centenarians than others, and this had suggested the idea of inter-marriage between long-lived families to test the rule: but when the various modes of killing off people now-a-days were considered, such as railways, steamboats, elevators, folding beds, electric lights, dynamite, &c., to say nothing of patent military machines for wholesale murder, it was really a wonder that there were any centenarians left at all. There were certain physical indications which gave clues to longevity and may be accepted as facts. A large heart, large lungs, brain and digestive powers, as well as large sexual organs, indicated long life. Good lungs were shown by wide, open, full nostrils. Small, pinched nostrils were nearly always signs of weak lung power. A person who appeared tall in sitting, and short and rather thick-set in standing, was more apt to live long, being endowed with a long trunk and short legs and arms. To all these general rules, however, there were many recorded exceptions.

IS IT PERMISSIBLE FOR DIABETICS TO USE SUGAR?

In a recent clinical lecture, Professor LEPINE, of Lyons, has related the case of a man, aged 60, who had suffered from moderate diabetes for twenty years, the average daily quantity of urine being about 60 ounces, containing about 18,000 grs. of sugar. Last winter, after an attack of influenza bronchitis, he became worse, lost a good deal of weight, and grew so feeble that he could hardly walk about his room. Regarding his case as hopeless, he allowed himself the indulgence of putting sugar in his wine, tea and coffee, and to his surprise he found that small doses of sugar amounting to 600 or 700 grs. had no ill-effect, but that his strength began to increase. At this stage he was seen by Professor LEPINE, who found him evidently improving, and permitted him to continue to use these small quantities of sugar. Professor LEPINE in his commentary recalls the fact that forty years ago, as may be seen by referring to the numbers of the *British Medical Journal* at that period, the treatment of diabetes by sugar was strongly advocated by BUDD, CORFE, SLOANE, and others upon purely empirical grounds. The cases given in support of this practice are, in the opinion of Professor LEPINE, wanting in those details which are indispensable to enable us to judge of their value, but he points out that there is nothing irrational in supposing that small quantities of sugar may be taken by diabetic patients without injury and even with advantage. Cane sugar is made up of equal quantities of glucose and levulose, and of late years it has been shown levulose can be tolerated by many diabetics in doses of from an ounce to an ounce and-a-half daily. Much also depends upon the rate at which the sugar is absorbed and the quantity taken at one time. Professor LEPINE suggests that small quantities of honey, which consists almost exclusively of levulose, may be tolerated even better than cane sugar, and he urges that it is not irrational to make carefully-guarded experiments with limited quantities of saccharine substances in the treatment of diabetes, for diabetic patients vary considerably in their tolerance of carbohydrate food, and this can only be determined by observation in each case.

THE EFFECT OF SOME CARDIAC TONICS AND OF SOME HYDRO-THERAPEUTIC MEASURES ON THE ARTERIAL PRESSURE IN INFECTIOUS DISEASES, ESPECIALLY ENTERIC FEVER AND PNEUMONIA.

In many infectious diseases, which in themselves are not very serious, it is the heart that is the danger, and failure of the heart's action is one of the commonest causes of death: hence the importance of the part played by cardiac tonics in these diseases. But our knowledge of the efficaciousness of the drugs in question is very indefinite—certain authors indeed, consider them to be more injurious than beneficial.

M. MERCANDINO has now studied, by means of the sphygmometer of Riva-Rocci, the effect of the commonest cardiac tonics on the arterial pressure in certain infectious diseases, especially enteric fever and pneumonia.

The result of these researches is not very encouraging. Thus in ten patients camphor, which had raised such brilliant hopes, had no effect upon the arterial pressure in three cases; in the other seven the elevation of pressure varied from three to ten millimetres of mercury.

As for the pulse, it was, as a rule, slightly diminished (from two to fourteen pulsations); in one case it was unaffected; in another it was accelerated by two pulsations.

Caffeine gave no better results: out of eight cases it was inactive, as far as the arterial pressure was concerned, three times; in the other five there was an elevation varying between three and eight millimetres. The pulse was unaffected in one case, was accelerated by four pulsations in two cases, and diminished from four to eleven pulsations in the other five.

We need not enter into details regarding strophanthus which actually diminished the arterial pressure on the fifth day of a pneumonia, or ether, which was almost always inactive, or alcohol in the form of marsh-mallows. This last, however, had a sufficiently marked influence upon the pressure: in ten cases it twice raised it 20 millimetres, once 14; unfortunately the beneficial action was inconstant.

The conclusion that the author draws, with good reason, from these researches is that the cardiac tonics, in infectious diseases, have only a slight action, less marked in proportion to the severity of the disease, and consequently to the greater urgency.

It is fortunately not the same with regard to hydro-therapeutic measures. M. MERCANDINO has studied, from this point of view, the cold bath, the gradually cooled bath, the tepid bath at 86°F., and the wet pack.

With the first of these measures, the pressure was always raised, on an average, 13 millimetres in 13 cases, while the pulse showed an average decrease of 15 pulsations. The gradually cooled bath and the wet pack had a similar effect, but less marked; the action of the tepid bath was more feeble and besides was unreliable.

From these data, the author believes himself justified in deducing a rational treatment of fever, of which the following are the elements:—

According to the age of the patient, his constitution, the manner in which he reacts, the gravity of the case, the amount of fever, he employs either the cold bath, the gradually cooled bath, or the tepid bath, reserving the wet pack for the intervals between the baths and at night. He only gives three baths a day, because of the trouble they involve upon the attendants.

When the rectal temperature, in spite of the hydro-therapeutic measures, remains for several days at about 104°F., he administers at night from 15 to 25 grains of chlorhydrate of quinine. He also prescribes this drug when the bath is contraindicated, as in intestinal hemorrhage.

THE PHYSICIAN'S TEMPERAMENT.

THE *Medical Brief* says:—Every man is influenced by his temperament. The physician is no exception. Temperamental peculiarities have more to do with our success than we begin to realize. It is a difference in temperament quite as much as any essential difference in knowledge, method or training which makes some doctors a power in the sick room, where others are negative.

Therefore self-knowledge and self-culture are very important to the physician. If he sees his lack of certain qualities necessary to reassure and encourage the patient, he will keep his misgivings and suspense to himself. If he recognizes that he is timid, uncertain, vacillating by nature, he will set to work to transmute these tendencies into positive characteristics. He will not rush into a rashly gloomy prognosis or speak doubtfully of medicine.

If he is inclined to be over-enthusiastic and radical, he will put the curb on himself and refrain from declaring that operation is, and must be, the only way to save or cure a patient. If he is too sanguine, he will learn to be a little slow in promising permanent cures or absolute relief.

In other words, he will endeavor to eliminate the elements of weakness which his temperament furnishes, and to strengthen his moral powers, so that his personal influence may aid him in curing disease.

There is no doubt that every physician carries an atmosphere with him which is either strengthening or depressing. We have all seen doctors who are wet blankets in the sick-room, and others whose mere presence stimulated all the vital powers.

If a man will practice medicine, he should try to see himself as others do, and get rid of faults of temperament, moods, and unlovely manners, which hamper his usefulness. Culture, discipline and health can almost make up for any natural lack, and these can be had if there is grit and determination to work for them. It is difficult to help others until we have helped ourselves. Mere knowledge can achieve little. There must be power back of it. Experience alone gives power.

So the doctor who has discovered his good and bad points, and has schooled himself to make the best use of his powers, can handle his patients to the best advantage. He knows how to make their minds aid their bodies; he knows how to draw out a true history of disease; he knows when a little advice will be acceptable, and when to make light of troubles without giving offence. Sympathy and tact become instinctive with him, and he knows just how to adapt his manner to the occasion and the person without seeming too much impressed. Such a doctor can get control of his patients. He soon has their confidence and co-operation, which is half the battle.

Mould your temperament to the exigencies of your calling if you would be a genuine healer.

DEATH OF A GREAT IRISH SURGEON AND JOURNALIST.

WE regret to have to chronicle the death of Dr. ARCHIBALD HAMILTON JACOB, B.A., M.D., F.R.C.S.I., the veteran journalist and eminent oculist of Dublin, which took place with

brief warning, on January 12th. For upwards of thirty-five years Dr. JACOB has had charge of the Irish department of the *Medical Press and Circular*, of which he was proprietor. His outspoken honesty of purpose and the intimate knowledge which he possessed of the medical poor-law service of Ireland gave great weight to his utterances, and he was the sworn enemy of all jobbery and humbug, from whatever quarter they hailed. Faithful to his principles, he attacked indifferently either friends or foes when their conduct failed to harmonize with his ideas of what was right and proper, his dominant principle being that the calling of medicine implied, or should imply, culture and refinement. Dr. JACOB was possessed of exceptional clearness of judgment, and expressed his views in terse epigrammatic English. He was a fluent writer and an able speaker, and rendered valuable assistance in all parliamentary affairs, of which he had many years' experience. The Irish Medical Association, which was the creation of his father, Dr. ARTHUR JACOB, owes its present prosperous condition largely to his fostering care, though on occasion he did not hesitate to purge away its faults. In private life Dr. JACOB was one of the most delightful of companions, full of anecdote, quick at repartee, and hospitable withal. Just to his enemies and faithful to his friends, though he spared not the rod, he was universally esteemed and respected. He was marked out as the most suitable representative of his College on the General Medical Council, but owing to failing health and other circumstances he never occupied that position. He was the most disinterested of men, scorning to intrigue for well-paid posts, and content to do his duty fearlessly, alike in his consulting-room and with his pen. Dr. JACOB was for many years Registrar of the Royal College of Surgeons in Ireland, and at the time of his death he occupied the position of Professor of Ophthalmology in the College; he was ophthalmic surgeon to the House of Industry Hospital, and oculist to the Lord Lieutenant. He leaves a wife and large family to mourn his loss.

TEST ALL THINGS : HOLD FAST TO THAT WHICH IS GOOD.

THE doctor, of all men, must avoid hobby-riding. He should be broad, liberal, of an enquiring turn of mind, and open to conviction. The utility of remedies and measures should rest upon their intrinsic merits, and their scope, or field, be determined entirely by commonsense and experience.

There are certain standard proprietary remedies essential to a man's clinical success. There are also alkaloidal remedies invaluable in their place. Eclectic and homoeopathic preparations are extremely useful at times. There are occasions when polypharmacy of the most empirical description exactly fills the bill. Witness WARBURG's tincture.

Every doctor has seen cases where crude opium or pulverised cinchona bark gave him better results than any of the alkaloids derived from them; and others where the intense but more limited action of the alkaloid was just the thing. The early American settlers carried both a broad and a narrow axe, each for its own kind of work; so with the successful therapist. He must familiarize himself with the indications and limitations of all the medicinal material with which science has armed him.

With certain delicately organized, very susceptible temperaments, the infinitesimal, frequently repeated, dose, with its single aim, is just right. The sturdier, more obtuse organisation responds better to the slow, diffused action of complex substances in larger dose at greater intervals.

Oftentimes the system responds much quicker to fluid preparations; but there are cases where a slow local action is preferable.

In considering what remedies shall be employed in every case, the temperament and constitution of the patient, together with the pathological principles operative, must be considered equally with the claims of various kinds of therapy. Sometimes a case will not bear any kind of medication at first. Then we must adapt hydrotherapy, massage, electricity, dieting, suggestion, until we get enough vitality to work on. Other cases have abundant life force, but like an unbroken colt, it breaks out in all kinds of perversities.

It requires much insight, skill and experience to steer successfully among the clinical perplexities which beset us, but hobby-riding will not simplify the work. It only prepares the way for a series of disappointments from which we learn nothing, but which, under a liberal system of practice, is our best guide and instructor. We may classify our knowledge as it comes to us, item by item, but we cannot generalize broadly from a single one.

Hobby-riding builds up arbitrary restrictions which are opposed to progress, and is narrowing in its influence. There is good in everything. To extract and apply it, under the rulings of commonsense and experience, is the true physician's province.

MISTAKES IN GYNÆCOLOGY.

In the address in Gynæcology at the Ottawa meeting of the Canadian Medical Association, Dr. WILLIAM GARDNER of the McGill University, discussed Mistakes in Diagnosis and Treatment; and we doubt if any of his hearers ever spent an hour in listening to wiser practical advice. We may mention some of the points upon which Dr. GARDNER instructed his audience. The importance of a proper method of examination: the very limited utility of the uterine sound; the frequent association of displacements of viscera; vaginitis as a cause of symptoms; the importance of always, when dealing with an abdominal swelling, bearing in mind the possibility of pregnancy, intrauterine or extrauterine; the gravity of ascribing hæmorrhages or unaccustomed discharges in women at the climacteric time to the "change of life" without examination, thereby overlooking cancer while yet in its curable stage; the duty, not only of discovering anything that is abnormal, but of estimating rightly the extent of its effect upon the patient's health, bodily and mental. There is nothing novel about any of these things. It is the commonness of the mistakes dwelt upon that makes it so desirable that the profession should be kept alive to the necessity of avoiding them and the disasters that come from carelessness in such matters. Dr. GARDNER's advice ought to sink deep into the minds of his hearers and his readers.

WANTED AN OFFICIATING "PROFESSOR" OF SURGERY FOR CALCUTTA.

THE Director-General, I. M. S., is once again in straits to find a "Professor" of Surgery and a "surgeon" for the Calcutta Medical College and Hospital. "Professor" R. D. MURRAY, of lithotomy and lithotripsy notoriety, has been granted furlough for six months, and the boat that is to convey him "Home" is timed to leave in the middle of March. Yet the Director-General is not ready with a substitute for the immortalised MURRAY of "Stone" fame. May we ask if all the Colonels and Lieutenant-Colonels of the I. M. S. in Bengal are considered too "weak" to

teach surgery and to operate on "stone" cases? If so, why not put in a private practitioner—an F. R. C. S.—one who puts on all the airs of a real live "professor" has, we believe, applied for the officiating post. Or why not apply to the India Office for a selection from one of the British hospitals? With Dr. HAVELOCK CHARLES away from the College Hospital, what is Calcutta to do without a surgical "professor." Of course the public need I. M. S. "Professors," but here we find the Director-General denuding the city of official surgeons. Both are to disappear from the scene of their labors together. This is surely as calamitous as it is unpardonable! But, we ask again, who is to temporarily succeed "Professor" MURRAY? This is a serious matter, and it behoves the authorities to look about carefully and select a thoroughly good, experienced and reliable surgeon, or it is high time the public protested against these slipshod, happy-go-lucky guesses at "surgeon-making."

FOURTEEN AND A HALF HOURS' ARTIFICIAL RESPIRATION IN A CHILD ONE WEEK OLD: RECOVERY.

G. E. KEITH, M. B., reports the case of a male child, aged one week, upon whom the operation of circumcision was performed for long and tight foreskin. Chloroform was the anæsthetic used; the child did not breathe well and lost more blood than usual. About fifteen hours later the child became dyspnoic and cyanosed, and when seen was apparently dead. Under artificial respiration breathing recommenced, to fall once more when the passive movements were stopped. The artificial respiration was continued for fourteen hours and a half, at the rate of twenty to the minute. Oxygen was used continuously, and heat was applied by means of a hot-water bottle. By the time normal respiration returned, the child's chest and upper abdomen resembled raw beef, and the arms were red and excoriated from the violent use to which they had been put. Recovery was very rapid. Twenty drops of brandy every hour were given and were well tolerated; a smaller amount seemed to cause a loss of ground on the part of the patient. The brandy was never noticeable on the breath; it was all used in the struggle for life.

FORMOL IN UTERINE HÆMORRHAGE.

SOLUTIONS of formaline were first employed by Dr. RANELLETTI, of Rome, in the treatment of inoperable uterine cancer. One of the advantages of the formaline applications he used was to stop the hæmorrhage which always accompanies this form of neoplasm.

The use of formol in gynæcology has since then been extended by Dr. GERSTENBERG, of Berlin. He states that he has succeeded in checking various forms of metrorrhagia by the application of a solution of formic aldehyde.

The following is his mode of procedure: Having seized the anterior margin of the cervix with a tenaculum, he passes a sound, carrying a tampon of cotton wool saturated with a 40% solution of formol, into the cavity of the uterus, and then twists it round and round. According to the case, he does this two or three times. Having withdrawn the sound, nothing remains but to place a plug in the vagina to protect the vaginal mucous membrane from the irritant action of the caustic, and to recommend that the patient should remain in bed for two days if possible.

In six cases in which it was employed, the method was completely successful, it was particularly efficacious in hæmorrhages at the "change of life," and in hæmorrhagic endometritis consecutive to abortion.

In addition to its hæmostatic effects, formol acts favourably by inducing strong uterine contractions.

SEDATIVE ENEMATA IN ECLAMPSIA.

It is known that the combination of several drugs having similar properties increases their activity. It is for this reason that a mixture of chloral, bromide of potash, hyoscyamus, and cannabis indica is constantly employed as a hypnotic where an excited state of the nervous system is the cause of insomnia.

Dr. POPESCU, of Czarnowitz, has tried a similar combination in the crises of eclampsia.

The following is his formula :—

Bromide of potassium	℥ss	℥i.
Chloral hydrate				
Extract of hyoscyamus		℥ss	...	grs. iv.
Extract of cannabis indica				
Liquid extract of Nigella	...			℥i.
Essence of the rind of bitter orange	...			℥v.

A tablespoonful of this mixture is given as an enema, usually three is not necessary. Dr. POPESCU has used this in a large number of cases of eclampsia, and always with complete success.

TOTAL ABSTINENCE IS SAFE.

Of the baneful possibilities of alcoholic indulgence medical men need no extra-professional evidence. To it can be traced no small measure of crime, disease and death. The appeal of the Commander-in-Chief of the British forces in South Africa, that the welcome of the troops returning to England "may not take the form of 'treating' the men to stimulants in public houses or in the streets, and thus lead them into excesses which must tend to degrade those whom the nation delights to honour," is therefore both timely and judicious. There may be legitimate differences of opinion as to the physiologic activity and the therapeutic utility of alcohol, as to what constitutes temperate or moderate and what excessive indulgence, but none will deny that those who abstain are on the safe side and assume no risk.

WHERE DOES ARSENIC NOT EXIST?

THIS is a question which will have to be answered some time soon, for it seems most difficult to be sure that anything which has gone through a chemical process is free from arsenic, unless special pains have been taken to get rid of it. We hear local authorities have recently purchased samples of borax from chemists, doctors, and grocers, and as the result of analyses all the vendors, with one exception, have been summoned under the Sale of Food and Drugs Act for selling an impure article. The public analyst has found arsenic in the specimens to the extent of from $\frac{1}{10}$ to $\frac{1}{4}$ gr. per lb., and even the borax of the vendor who was not summoned contained a trace, but so little that the authorities would not risk a prosecution.

DEADLY SERUM.

THE use of diphtheria serum is likely to receive a severe check in Italy. The Serotherapeutic Institute of Milan made a batch of the serum on November 24th, into which the tetanus bacillus was accidentally introduced. The result has been that eight persons on whom the serum was used have met with horrible deaths from tetanus. The Institute has been closed by the Prefect, the stocks of serum destroyed, and steps taken to recall the supplies in the hands of dealers. The accident has caused somewhat of a scare amongst the public and the medical profession in Italy, and, it is thought, may check the use of the serum in other countries as well.

MALARIA WITHOUT MOSQUITOES.

F. SEMMLER, M.D., writes to the Editor of the *Medical Record*, Cordoba, Mexico. Once more malaria and mosquitoes. There is a railroad being built from here running south and east to join the railroad of the Isthmus of Tehuantepec at a certain place. At a distance of 93 km. from Cordoba is a marshy plain with a few houses and no drinkable water. The place is called "Tierra blanca." When I went there I was greatly surprised not to find any mosquitoes, and yet the place is a first-class malaria breeder.

MEDICAL DEPARTMENT OF THE QUEEN'S HOUSEHOLD IN SCOTLAND AND IRELAND.

THE following is a list of the officers of the Medical Department of the late Queen Victoria's Household in Scotland and Ireland respectively :—

SCOTLAND.

Physicians in Ordinary: Sir W. T. Gairdner, K.C.B., M.D.; G. W. Balfour, M.D. *Surgeons in Ordinary:* P. H. Watson, M.D.; A. Ogston, M.D. *Surgeon Oculist:* D. A. Robertson, M.D. *Surgeon-Dentist:* J. Smith, M.D.

IRELAND.

Physicians in Ordinary: Sir J. Banks, K.C.B., M.D.; W. Moore, M.D. *Surgeons in Ordinary:* Sir P. O. Smyly, M.D.; Sir W. Thomson, M.D. *Surgeon Oculist:* C. E. Fitzgerald, M.D. *Apothecary:* J. Evans.

REVISED LEAVE PAY FOR WARRANT GRADES.

The following are the recently sanctioned revised rates per annum of leave pay for departmental officers with warrant rank and warrant officers of the Indian Army Department and Indian Subordinate Medical Department. They apply to leave out of India, and take effect from 1st April next :—Deputy Assistant Commissary, £125; Conductor, £100; Sub-Conductor, £90; Senior Assistant Surgeon with the honorary rank of Lieutenant, £125; Assistant Surgeon, 1st class, £120; 2nd class, £90; 3rd class, £70; 4th class, £50. A non-commissioned officer promoted to warrant rank during furlough will be paid accordingly with effect only from the date from which the rate of leave pay admissible to a Sub-Conductor operates to his advantage.

"JACOB MEMORIAL."

IT is proposed by many of the friends of the late Dr. ARCHIBALD H. JACOB, Dublin, to raise a memorial in testimony of his life-long work in the interests of the profession. Subscriptions may be forwarded to Sir CHARLES CAMERON, C.B., 51, Pembroke Road, or Dr. L. H. GEMMEL, Vice-President, R. C. S., 92, Merrion Square, West, Honorary Treasurers, or to Mr. G. F. BLAKE, Registrar, Royal College of Surgeons, Stephen's Green, West.

SHORT ITEMS AND PERSONALITIES.

Deputy Surgeon-General C. E. Raddock, I.M.S. (retired) died at Norwood on the 5th ultimo. He served under Sir Colin Campbell in the Mutiny, and was present at the relief of Lucknow in November 1857, the actions of Cawnpore, Serai Ghat, etc., and was with the Jaunpore Field Force from January to April 1885, and also saw fighting in the Bhootar campaign (1865) and in Afghanistan (1879).

Major J. C. Morgan, R.A.M.C., who was lately for two years Staff Surgeon of the Punjab Command Headquarters, has been appointed Medical Officer of the Duke of York's Royal Military School at Chelsea. The appointment is a just recognition of the excellent work done by Major Morgan when in charge of headquarters during the Tirah campaign.

"To give what none can measure, none can weigh,
Simply to go where duty points the way.
Faith, honor, duty—duty calmly done,
That shouts no self-praise o'er a victory won;
One bugle note their battle call,
One single watchword, DUTY—that is all."

—WILL MITCHELL.

The opium revenue in Bengal, to the end of December shows an excess of 5,555,845r. over estimates, and to the end of November in Bombay an excess of 432,350r.—nearly ten lakhs of rupees to the good in spite of the unsettled state of China.

Surgeon-General Spencer, Principal Medical Officer Punjab Command, who has lately once acted as Director-General, Indian Medical Service, will probably officiate as General Harvey when the latter proceeds on furlough.

Mr. J. B. Story, M.B., F.R.C.S., has been appointed Surgeon-Oculist to His Excellency the Lord Lieutenant of Ireland, in the room of the late Dr. A. H. Jacob. Mr. Story is Senior Surgeon to the St. Mark's Branch of the Royal Victoria Eye and Ear Hospital, Professor of Ophthalmic and Aural Surgery, Royal College of Surgeons in Ireland, and General Secretary of the Royal Academy in Ireland.

Lieutenant-Colonel J. Watson, B.A.M.C., in medical charge of the Station Hospital at Darjeeling, will, on being relieved by Major C. R. Bartlett, B.A.M.C., on the 1st of March 1901, proceed to Jhansi for officiating medical charge of the Station Hospital there.

The recommendation of the Civil Veterinary Department to send thirty students of the Punjab Veterinary College to South Africa has been accepted by the Military Department, provided that they pass the necessary examinations.

Lieutenant-Colonel James Clarke, I.M.S., until lately Civil Surgeon of Sialkot, died at Lahore on Friday morning after a long illness.

Lieutenant-Colonel Percy deHaga Haig, Indian Medical Service (Bengal), Principal Medical Officer, Malakhand Force, is permitted to retire from the service.

Lieutenant-Colonel Moran, I.M.S. (Bengal), has been advanced to the higher position of his grade, *vice* Lieutenant-Colonel Russell, retired.

Messrs. Peter N. Lakshmanan, M. B. C. S., and Henry Bailey Mylvaganam, L. M. and S., have both passed the first examination for the F.R.C.S., Eng.

An exchange has been sanctioned between Lieutenant W. M. Pearson, I. M. S. (Madras), and Lieutenant J. C. S. Oxley, I. M. S. (Punjab).

Volunteers are being called for amongst Veterinary Assistants in India to replace thirty Civil Veterinary Surgeons whose engagements in South Africa are expiring.

The services of Major Philson, R.A.M.C., are about to be applied for appointment as Surgeon to H. B. Lord Hope- town, Governor-General of Federal Australasia.

Major Daly, I.M.S., has been appointed Base Store-keeper, China Field Force.

Major Frederick Pinsent Maynard, I.M.S., M.D., L.R.C.P., D.P.H., has passed the second examination for the F.R.C.S., Eng.

WANTED—A POST BY AN ASSISTANT SURGEON willing to serve in a Native State in the Railways or any Municipality, &c. Apply V., C/o *The Manager*.

Members of the Indian Medical Association will kindly note that while the entrance fee to the Association is fixed at Rs. 5, the annual subscription is reduced to Rs. 2.

The Indian Medical Association fights the battles of the Medical Profession as a whole, and it takes up the cause of individual members as well. Join the Association and you will not be disappointed.

Medical Appointments, Transfers, Exchanges are easily and cheaply effected through our special short advertisement page. See terms and apply at once.

News items of medical interest from all parts of the Indian Empire are asked for by the Editor for publication in the *Record*.

Current Medical Literature.

MEDICINE.

Malarial Peripheral Neuritis.

THAT malarial fever will cause peripheral neuritis has not until recently been recognised, and this is another instance of the isolation of a disease and its precise definition and description being followed by a great increase in the number of its known causes. Not so long ago peripheral neuritis was regarded as almost exclusively due to alcoholic excess, particularly in females; now many other causes have been found effective, and the malarial origin of the malady is supported by cases recorded in a valuable paper by Dr. CAMPBELL HIGHT. This article appears in the *Journal of Tropical Medicine* and is entitled *Malarial Peripheral Neuritis*. The affection is preceded by intermittent fever, or more commonly by very frequent attacks of remittent fever. It is only after these attacks have lasted for months that severe symptoms appear. These are at first pain and weakness in the knees and legs, coming on only in the evening after the day's work. Pain is often very severe, and is attended with weakness. The weakness gets more marked; eventually paralysis may ensue. A curious feature is the tendency of the paralysis to pass off and recur. Palpitation is often complained of. The malady is very well illustrated by the records of cases, and the author proceeds to consider its etiology. He regards the nervous affection as being caused by a toxin, itself the product of the malarial germ. In this respect it differs from the neuritis of leprosy. In the latter the actual germ is present in the tissues, whereas in the former only that indefinable nebulous something which, in our ignorance, we call a "toxin," is at work. The author remarks that the neuritis is readily curable, implying, of course, that the patient is removed as soon as possible from malarious influences. Further, it appears that it is only after repeated attacks of malarial fever that peripheral neuritis occurs; single attacks are hardly ever followed by the nervous symptoms. The resemblance of the disease to beri-beri is of course apparent, and a valuable table is given by the author, by means of which the differences between the diseases are readily recognisable. A patient who has once been attacked by peripheral neuritis of malarious origin should, if possible, avoid the tropics for the rest of his life. If compelled to return, the author considers a residence in the large cities should be insisted on, though even then the patient is not safe from exposure to malaria.—*Treatment.*

Bromide Sleep in the Treatment of Acute Mania.

MACLEOD recommends the bromide sleep in the treatment of acute mania. The method he uses to induce this condition is to give the drug only in the daytime, two drachms in a half tumbler of water every two hours until an ounce is given the first day. On the second a similar amount is given in the same manner. This may suffice to produce the sleep which will not be at its deepest until the fourth or fifth day. It is a safe rule in any event to cease the administration of the drug for 24 hours, when drowsiness is so profound that the patient cannot be aroused, or if, when aroused, the talk is incoherent. The condition lasts from five to nine days, during which time the subject sleeps day and night and cannot be aroused. He is unable to stand, sit or speak, or to carry on any of the higher cerebral functions. He will

not eat or drink, nor is he capable of waking for either, being unconscious of such needs. He can, however, be sufficiently nourished with milk. He will pass urine and feces into the bed if left to himself, but can be prevented from doing this if placed on the commode and held there for a few minutes every six hours. During this sleep the higher nerve-centres are arrested to an extent that cannot be attained in any other way. The recovery is gradual and is complete in about 21 or 24 days. MACLEOD has induced this condition safely nine times, and with advantage, in the treatment of the morphia habit, the chloral habit and acute mania. One patient died on the seventh day of treatment from an attack of double pneumonia, which was not thought to have any connection with the treatment.—*Phil. Med. Jour.*

Aneurism of the Aorta treated by the Insertion of a Permanent Wire and Galvanism (Moore-Corradi Method), with a Report of Five Cases.

DR. GUY L. HUNTER (*Bulletin of the Johns Hopkins Hospital*) says:—A black varnish or lacquer makes the best insulation for the needle. The disposition of the wire in the lumen of the sac is an important factor in the amount and the effectiveness of the fibrin whipped out. A small quantity of wire possessing a good spring should be selected. Cure of the aneurism demands as complete contraction as possible of the sac wall upon the clot formed at or soon after the operation. The wire should be of such amount and material as not to interfere seriously with this contraction. The corrosion of the wire by the electric current makes a rough surface very conducive to the rapid whipping out of fibrin. Within certain limits, the wire most easily corroded is to be preferred. The sac should never receive both poles, and the negative electrode should never be in the sac. Sepsis is an omnipresent danger. Another danger is that of the development and rupture of a secondary sac due to the rapid filling up of the main sac by coagulum, and the shunting of the blood stream against a portion not receiving a special strain before. There have been in all twenty-three operations of this character including the author's five. Clinical and post-mortem evidence points to the efficacy of this method. Thirty-nine per cent. of successful results attest the value of this method, and the fact that it is still in its infancy, and most crudely applied, makes the record very impressive.

Two Cases of Acute Hæmorrhagic Pancreatitis.

DR. J. H. BRYANT reports two cases of acute hæmorrhagic pancreatitis occurring in men aged thirty-six and twenty-two years respectively. In both cases the disease was ushered in with an attack of acute abdominal pain rapidly leading to collapse. Both cases underwent laparotomy, but succumbed within twenty-four hours of the operation. In the first case areas of fat necrosis were found throughout the peritoneal cavity, which contained a good deal of blood-stained fluid. No trace of any normal-looking pancreatic tissue was to be seen. The position of the pancreas was occupied by a chocolate-colored mass, three times as large as a normal pancreas, consisting of blood. Marked fat necrosis of the mediastinal and pericardial fat was observed. There was no peritonitis. In the second case there was general acute peritonitis. The pancreas was much enlarged and adherent to the adjacent structures. There were many little infiltrations of blood into its parenchyma. The peritoneal cavity at the time of the operation contained a large collection of clear, bile-stained, serous, sterile fluid. No fat necrosis was found. The existence of fat necrosis outside of the peritoneal cavity, as occurring in the first case, is of great interest.

SURGERY.

Surgical Aspects of Modern Small-Bore Projectile.

SCHACHNER (*Annals of Surgery*) says that all advanced nations have practically the same character of rifle and projectile, and that the modern small-bore projectile is capable of producing wounds of both humane and a gruesome nature. The nature of the wound produced by the small-bore projectile is either dependent upon the intervening distance, or the character of the structure wounded, or both. The precise manner in which the explosive action is developed in structures filled with or rich in fluid is still *sub judice*. The weight of evidence and the majority of authors favor the hydrodynamic rather than the hydraulic theory. The new projectile is propelled with greater energy, velocity, and accuracy; it is lighter, has a smaller frontage, and is less liable to deformation on striking the object. It has less disabling capacity, and on the whole produces wounds of a more humane character than the old leaden bullets. By explosive action is meant the damage created in structures outside the projectile's path. At 800 or 1000 yards explosive action is occasionally met with, and then only in the skull or in parts of the body filled with and rich in moisture. The rotary action of the projectile may continue after its penetrative movement ceases, and the character of the wound is largely dependent upon this rotation.

Inherited Syphilis.

FINGER has undertaken to collect, sift, and review all the literature bearing upon hereditary syphilis, and concludes, as against KASSOWITZ, who believes in unavoidable heredity, that inherited syphilis is a myth, and that transmission of the disease to the fetus depends upon mechanical admixture of syphilitic virus to the ovular or spermatic elements furnished by the infected parent. FINGER further concludes from his research:—

1. Undoubted inheritance of strictly paternal, and
2. Of strictly maternal syphilis;
3. Maternal syphilis is transmissible to the fetus through the ovum, and also during pregnancy *per placenta*.
4. Syphilis acquired by the mother, even in the last month of pregnancy, may infect *in utero* the child of otherwise healthy parents.
5. The presence *in utero* of a fetus infected with paternal syphilis affects the maternal organism in various ways. Either the mother becomes infected (*choc en retour*) or not, while she becomes immune to subsequent syphilitic infection, or, again, she remains perfectly healthy.
6. FINGER recognizes an early form of conceptional syphilis characterized by the immediate occurrence during pregnancy of secondary manifestations—in the absence of a primary lesion—and also a tardy form of conceptional syphilis characterized by the immediate occurrence of tertiary lesions, in the absence of primary or secondary manifestations.
7. By far the largest number of women who escape infection while bearing the offspring of syphilitic fathers acquire it, and by means of, their pregnancy an immunity against subsequent syphilitic infection (COLLES'S law).
8. In the same way do children of syphilitic parents, who escape infection *in utero*, develop immunity toward acquired infection (PROFETA'S law).—*Med. Age.*

Intra-peritoneal Infusion of Saline Solution.

For the gradual introduction of saline solution into the peritoneal cavity after severe operations, EISEL (*Archiv für Klin. Chir.*) has adopted the following method: Before closing the wound a No. 18 catheter is inserted at the lower angle and carried down into DOUGLAS'S pouch. The wound is sutured in the usual manner, and the catheter is cut off and its end secured with a wire suture and attached to a glass irrigator. After the dressings have been applied, a continuous flow of saline solution is begun and maintained for twenty-four hours at the rate of one cubic centimeter a minute. This is effected by compressing the supply tube with a clamp fitted with a millimeter screw. About three pints of fluid is introduced in twenty-four hours.

A case of rupture of the liver, with profuse hæmorrhage, is cited, in which three quarts of saline solution was injected into the peritoneal cavity in two days, the patient making a good recovery without any other stimulation. It was estimated that fully two quarts of blood was lost.—*Med. Age.*

Principles and Treatment of Stuttering.

R. COEN (*Therapeutics*) lays down five principles of treatment which he thinks essential to success in the therapeutics of stuttering: (a) Properly conducted breathing gymnastics, special attention to be paid to the deep, continued inspiration, the short expiratory movement of the breath, the gradual prolonged expiration, and the holding of the breath. (b) The regulation of vocal and speech-producing organs, to be accomplished by enumerating slowly the vowels and diphthongs. (c) Obtaining control of the disturbance of innervation by elimination of the spasmodic periods which occasion disturbances of innervation. (d) Exercising and strengthening the patient's will power. (e) Stimulation and toning up of the general system.

Nail in the Trachea for Two Months: Extraction by a Magnet.

DR. GARREL (*Lyon Médical*) says:—A child, aged 20 months, swallowed a nail 2 inches long and became cyanosed. When the cyanosis had disappeared, the nail was thought to have passed into the œsophagus, but it was not found in the stools. A radiograph showed the foreign body in the trachea. As the child was getting thin, it was decided to remove the nail, and tracheotomy was performed. The nail was not touched by the canula, which was raised, and into the wound held open by a dilator a powerful straight electro-magnet was introduced. The nail soon approached the magnet and was extracted.

Treatment of Tetanus by Bacelli's Method.

THIS consists in the administration of a 2 or 3 per cent. solution of carbolic acid in doses of 3 to 4 centigrammes several times a day, as much as 35 centigrammes being given in one day without ill-effects. ASCOLI, in a monograph, states that in 38 cases there was only one death, and in this the treatment had been less energetic. Morphine is used during the first few days to allay insomnia and hyperæsthesia.—*Novidades Médico-Pharmacológicas.*

OBSTETRICS AND GYNÆCOLOGY.**A Case of Superfecundation.**

DR. DOMENICO POMARA discusses the various theories of superfecundation, superimpregnation, and superfestation, and reports the case of a primipara, aged nineteen years, who had given birth to a boy shortly before the author was called to see her. A few days later she complained of a feeling of fulness in the lower part of the abdomen, and without examining her, the author assured her that this sensation was due to the fact that the womb had not yet completely contracted. The puerperium was perfectly normal, and after a few days the patient was allowed to leave her bed. But the sensation of fulness and swelling did not disappear, and the author, having been called again, examined the patient, and to his surprise found the uterus enlarged to about the size that corresponds to the fourth month of pregnancy. There was a uterine souffle, and the woman said that she had felt foetal movements. Knowing that she had recently been delivered, the author attributed the movements to flatulence, and the swelling to some lesions in the generative organs. He advised an expectant plan of treatment. After observing the patient for one month, he was no longer in doubt, for the increase of the uterine tumour, the intensified uterine souffle, the sympathetic disturbances of pregnancy, and the foetal movements, pointed to a new pregnancy. The further course of events justified the diagnosis, and the woman was delivered of a second child on June 13, 1896, six months after the first labor. The previous history of the patient was as follows: She was married at the age of sixteen and remained sterile for three years, during which time she was treated by gynecologists for stenosis of the cervix. In 1895, a year before the first labor, she had an attack of metritis and salpingoophoritis of the right side. She was advised to abstain from coitus, but when she returned to her home cured, she speedily became pregnant.—*New York Med. Rec.*

Fifty-eight Cases of Eclampsia without a Death.

PROFESSOR STROGANOFF reviews fifty-eight consecutive cases of eclampsia, all the patients recovering. He regards the disease as an acute, infectious one, with a short course, rarely extending over twenty-four hours, almost never over forty-eight. After the first attack, morphine and chloral combined are given repeatedly until the patient is completely narcotised. He regards it as desirable to keep the patient in this condition for from twenty-four to forty-eight hours, according to the severity of the attack. Strict attention must be paid to the regular functional activity of the heart and lungs; that of the former may be fostered by rectal infusions and the ingestion of fluids by mouth during the periods of consciousness. All possible sources of irritation must be avoided, while a safe, but rapid, method of delivery must be chosen. The author adds thirteen additional cases treated by these measures, all of which resulted in a recovery of mother and child. From sixty to seventy-five grains of chloral hydrate, and from one to two grains of morphine, were used on an average.—*New York Med. Rec.*

Two Cases of Total Vaginal Hysterectomy for Puerperal Infection.

DR. JORFIDA says:—Both patients recovered, and he adds these cases to a list of thirty-three which he has

collected from literature. Of these, twenty-two recovered and thirteen died. Of the total number previously reported, nine cases were abdominal hysterectomies (five recovered, four died), ten were supravaginal hysterectomies (nine recovered and one died), ten were cases of vaginal hysterectomies (four recovered and six died), and one case of abdominal-vaginal hysterectomy (recovered). Of the remaining three (one recovered and two died), the method of hysterectomy was not specified. If we add the author's cases to the four recoveries from vaginal hysterectomy in puerperal infection which are recorded, the mortality with this procedure is fifty per cent. This would seem to indicate that vaginal hysterectomy is the operation least suitable for these cases; and yet, in general, the best results are obtained from the vaginal method, among other reasons, because with this method diffusion of the infection to the peritoneum is less likely, and drainage is better. The figures of the writer are, however, too small to warrant any definite conclusion, and therefore this apparent contradiction may be disregarded, or may be explained by the greater gravity of the cases operated on by the vaginal route.—*New York Med. Rec.*

Ectopic Pregnancy.

BALDWIN first notices the earlier dicta of LAWSON TAIT as to the impossibility of diagnosing ectopic pregnancy before rupture, and remarks that in the last ten years we have come to know a great deal more of that condition, and there are many cases in which symptoms arise where a presumable working diagnosis is possible. There are no pathognomonic symptoms, but usually we find the following: There is a history of several years of sterility (with many exceptions); missing of a menstrual period or two (with exceptions); some unusual pain in the pelvis situated usually in the region of an ovary, possibly for a few days more or less irregular hæmorrhage, while there is generally to be found on one side or another of the uterus or back of it a fusiform cystic tumor, quite symmetrical in outline, painful on pressure, with usually evidence of pulsation. With these phenomena it is reasonable to suspect extrauterine pregnancy. Too much stress, however, must not be laid on menstruation or sterility. The pain is usually sharp and colicky, or it may be of a dull throbbing constant character. When the presumable diagnosis has been made, operation is advisable. He reports eleven cases.—*Jour. Amer. Med. Assoc.*

Radical Operation for Uterine Carcinoma.

PROFESSOR E. WERTHEIM points out the insufficiency of vaginal hysterectomy and the present groundless fear of the high mortality of twenty years ago of the abdominal operation. The latter is the operation to perform at the present day, as it is essential, to secure permanent freedom from recurrence, to extirpate the glands in the pelvis as well as the parametrium. Of thirty-three cases in which this course was followed, eleven were found to have glandular involvement—a sufficient number to justify the operation theoretically. As it is impossible in every case to diagnose glandular and parametritic involvement, the abdominal route, including their extirpation, should be chosen. None of the thirty-three cases has yet shown a sign of recurrence.

PHYSIOLOGY, PATHOLOGY, AND BACTERIOLOGY.

Our Present Knowledge of the Neuron.

AT a recent meeting of the German Scientific and Medical Congress, Professor VERWORN (*British Medical Journal*) discussed the hypothesis that the nerve cells (ganglion cells) and nerve fibres (nerves) form one cellular entity, and that the nerve fibres, in the same way as the protoplasmic branches of the cell, are only terminals of the ganglion cell body. In this way the neuron is the cellular element of the whole nervous system. This doctrine the speaker referred to as having been founded on anatomical, embryological, and experimental investigations made about ten years ago. Since then many workers have been occupied with the finer structure and the connections between the various neurons. As regards the former point, fibrille had been shown to exist, which might be the basis for the conduction of stimuli. Concerning the links, the researches of HALL and others seem to have shown that in many cases there is a real continuity of neuron substance, and that the fibrille partially pass from one neuron to another. As to the function of the ganglion cells, Professor VERWORN described the theory of MATHIAS DUVAL, according to which the protoplasmic processes are contractile, fatigue during the course of the day leading to shortening, and producing the sensation of sleepiness, sleep being required to allow the processes to stretch again. This idea was described by Professor VERWORN as mere hypothesis. Another point in dispute was whether in every case nerve stimulation must pass through the ganglion cell; whereas there were some arguments against this, there appeared to be no doubt that these bodies are the real seats of specific nervous processes. Impulses have their origin in them, and in them is regulated the intensity and duration of these processes, the fibres having only the capacity to conduct, not modify.

Tuberculous Lesions.

EDMUND OWEN (*The Canadian Journal of Medicine and Surgery*) says three important facts in connection with tuberculosis should be remembered, viz., the disease is communicable, it is preventable, and it is curable. With reference to the latter, he draws the following conclusions: (1) Chronic inflammation of a joint in a child or young person is always tuberculous, except in those very rare cases in which it is due to hereditary syphilis or osteoarthritis. (2) Tuberculous inflammation may completely destroy a joint, and then leave it solidly and soundly synostosed, without the surrounding tissues or the skin having been implicated, as in *caries sicca*. (3) If tuberculous granulation-tissue breaks down into a fluid, that fluid is not pus, and the collection is not, properly speaking, an abscess, unless by bad fortune or by worse surgery it has become infected by septic micro-organisms. (4) The fluid collection is not to be treated as an abscess—by incision and drainage, that is—but is to be opened and emptied and scraped and cleaned of its unhealthy lining of granulation-tissue. Then the wound in the skin is to be completely closed by sutures, firm pressure is to be evenly applied, and the part is to be kept absolutely at rest—by a splint if practicable. (5) The author has failed to discover that iodiform is of any peculiar value in the treatment of tuberculous lesions. At any rate he has long since discarded it, and has not noticed any falling-off in the results in consequence. He says there may be a small class of cases of angular deformity of the spine which should be treated by *forcible rectification*; but the application of such a procedure must be very limited. In the treatment of vertebral *caries* he insists upon securing absolute rest by putting the child flat on his back in a pillowless bed. There are all sorts of schemes, corsets, apparatus and braces for treating spinal caries without keeping the child flat. But they are all wrong in theory and in practice; and if every case of spinal disease could from the beginning be treated by continuous rest in the horizontal position, there should be no more of those unsightly humps to invite speculative interference.

Researches in the Etiology of Cancer and the Pathogenic Blastomycetes.

LEOPOLD speaks of the results of his investigations of this subject as follows: There can be seen in the fresh tissue of almost every malignant neoplasm brilliant bodies, partly round, partly biscuit-shaped, in which can be shown reproduction and segmentation. These bodies, which were not confused with cood or degenerated cells, could be considered only as blastomycetes, by the fact that they were not changed in a solution of caustic soda or potassa, or in hydrochloric or nitric acid. After many trials pure cultures of blastomycetes were obtained from four malignant human neoplasms. These were obtained from a cancer of the ovary, from a cancer of the breast and the axillary glands, and from cancer of the uterus. The blastomycetes were therefore obtained from a fresh cancer of the ovary. The pure culture can be obtained from fresh carcinomatous tissue. The infection of this pure culture in the testicles of a rat was followed by the development of a large number of nodules in the peritoneum to which the animal succumbed. Blastomycetes taken from these nodules give pure cultures. Consequently, there is no doubt that blastomycetes can be the cause of malignant neoplasms in man, and that inoculated into an animal they cause a neoplasm in it, which destroys life.—*Annales de Gynecologie et d'Obstetrique.*

Physiology and Pathology of Inheritance, or what do we Inherit from our Parents?

DR. T. OLIVER, summing up the subject as to what is inherited from our parents, says that from a physiological point of view there is considerable evidence to show that mental, not less than physical, qualities are transmitted; that pathologically such a disease as hæmophilia is inherited; and that, where there is a family history of phthisis and cancer, there is, especially as regards phthisis, a greater liability to the disease than where a family shows no such record. Tuberculous disease is inherited, but only in the form of an enfeebled resistance on the part of the tissues.

Determination of the Functional Integrity of the Kidneys before Operation by Means of the Freezing-Points of the Blood and Urine.

HERMANN KUMMEL (*Munchener medicinische Wochenschrift*) gives these four points as being the most useful in indicating whether the state of "the other kidney" is such as to permit extirpation of the diseased organ: (1) Estimation of the urea. (2) Determination of the freezing-point of the blood. (3) Determination of the freezing-point of the urine, if possible, obtained from the two kidneys separately by ureteral catheterization. (4) Examination of the separated urine from the two kidneys, with and without the previous administration of phloridzin or methylene blue. The value of the blood investigation, which gives far more reliable results than the urea determination, rests on these facts. The degree of concentration of any solution is directly proportional to the distance its freezing-point lies below that of distilled water, and the normal freezing-point of human blood has been found to lie between 0.55° and 0.57°C. If the kidney function is impaired, an increase in the amount of solids takes place, with a corresponding lowering of the freezing-point. If one kidney has been thrown out of function, but the other is capable of carrying on the work unaided, i.e., when a nephrectomy would be permissible, the freezing-point will invariably be found to be normal, and, *per contra*, if this is lower than the limit given, operation is contraindicated. The urine examination is conducted on similar principles, but is less reliable in practice, owing to the physiological variations being much greater.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Effective Sterilization of Excreta from Typhoid Patients.

CUMMINS describes a method for the effective sterilization of excreta from typhoid patients. A 30-gallon iron "jackpot," containing 2 gallons of 1 in 20 carbolic solution, was kept boiling day and night, and the fæces and urine were emptied into this solution as soon as they were passed; there was practically no smell; the vapour had a heavy odour redolent of carbolic acid, but at 1 or 2 yards distance it was scarcely perceptible. The apparatus has been in use for nearly two months, during which time over 200 cases of enteric fever have been under treatment. No case of enteric fever has occurred among the orderlies employed in nursing and for pioneer work. A control experiment was made by inoculating one nutrient agar tube from the contents of a bedpan that the attendant was about to empty into the cauldron. The stool was poured into the cauldron, and 10 minutes after five nutrient agar tubes were inoculated from the contents of the pot. All the tubes were incubated at blood-heat for 24 hours. The tube used as a control showed about 100 well-marked colonies, while the five infected by the contents of the pot showed no sign of bacterial growth.

Fainting and other Fits.

It is astonishing what an amount of ignorance exists in regard to some of our commonest ailments, and as fainting and other fits are of such frequent occurrence, and as everyone should know how to act in an emergency of this kind, it will, we think, be of interest to our readers to know what a celebrated physician recently said:—"I wish you would do something to teach people the difference between a fainting fit and an epileptic fit. You see, a fainting fit is produced by the blood leaving the head. It is important to remember this, because it determines the method of treating these afflicted people when no doctor is near, and because everyone occasionally finds it his duty to go to the help of some person in a fit, without a moment for reflection, let alone inquiry. If a person faints, he ought to be laid down flat on his back, for this will facilitate the return of blood to his head. Indeed, nature has provided for this, for a person who faints will fall down and soon recover if no one interferes. On the other hand, a person with an epileptic or cataleptic fit, indicated by convulsions and frothing at the mouth, ought to be propped up, so as to facilitate the flow of blood from the head to the lower parts of the body, which may be still further promoted by slapping the palms of the hands. Now, I cannot account for it, but the fact is that all ignorant people, in an emergency, reverse this treatment. A person who simply faints is carefully supported in a chair, and the face is plied with cold water applications, fanned, the result being that the fainting is prolonged. On the other hand, a man who drops in the street with epilepsy or catalepsy is invariably laid flat on his back, which in some cases is enough to kill him."

An Important Legal Decision: Physicians not liable when they act in Good Faith.

ACCORDING to the *Journal of the American Medical Association*, the Supreme Court of Massachusetts, in full bench, has given out a decision that is of the greatest interest and importance to medical men. It holds that physicians under the Massachusetts statutes are not liable for negligence in erroneously certifying a person as insane or inebriate, provided they do so in good faith and without malice. Even

if their examination was a careless one, their action was not the proximate cause of the commitment, as a judge must, under the statutes, determine that; and secondly, they should, in accordance with public policy, be, like other witnesses, considered privileged and protected against liability as long as they act in good faith and without malice. The opinion, says the Journal, was a majority one, but, while not unanimous, it is sufficient to protect Massachusetts physicians from vindictive damage suits, and may be a valuable legal precedent elsewhere.

Medico-legal Relations of the X-rays.

THE routine employment of the x-ray in cases of fracture, says J. W. WHITE (*American Journal of Surgery and Gynecology*), is not at present of sufficient definite advantage to justify the teaching that it should be used in every case. If the surgeon is in doubt as to his diagnosis, he should make use of this as of every other available means to add to his knowledge of the case, but even then he should not forget the grave possibilities of misinterpretation. There is evidence that in competent hands plates may be made that will fail to reveal the presence of existing fractures, or will appear to show a fracture that does not exist.

In the regions of the base of the skull, the spine, the pelvis, and the hips, the x-ray results have not as yet been thoroughly satisfactory, although good skiagraphs have been made of lesions in the last three localities. On account of the rarity of such skiagraphs of these parts, special caution should be observed, when they are affected, in basing upon x-ray testimony any important diagnosis or line of treatment.

As to questions of deformity, skiagraphs alone, without expert surgical interpretation, are generally useless and frequently misleading. The appearance of deformity may be produced in any normal bone, and existing deformity may be grossly exaggerated.

It is not possible to distinguish, after recent fractures, between cases in which perfectly satisfactory callus has formed and cases which will go on to non-union. Neither can fibrous union be distinguished from union by callus in which lime salts have not yet been deposited. There is abundant evidence to show that the use of the x-ray in these cases should be regarded as merely the adjunct to other surgical methods, and that its testimony is especially fallible.

The evidence as to x-ray burns seems to show that in the majority of cases they are easily and certainly preventable. The essential cause is still a matter of dispute. It seems not unlikely, when the strange susceptibilities due to idiosyncrasy are remembered, that in a small number of cases it may make a given individual especially liable to this form of injury.

In the recognition of foreign bodies the skiagraph is of the very greatest value; in their localization it has occasionally failed. The mistakes recorded in the former case should easily have been avoided; in the latter they are becoming less and less frequent, and by the employment of accurate mathematical methods can probably in time be eliminated. In the meanwhile, however, the surgeon who bases an important operation on the localization of a foreign body buried in the tissues should remember the possibility of error that still exists.

It has not seemed worth while to attempt a review of the situation from the strictly legal standpoint. It would vary in different States and with different judges to interpret the law. The evidence shows, however, that in many places and under many differing circumstances the skiagraph will undoubtedly be a factor in medico-legal cases.

The technicalities of its production, the manipulation of the apparatus, etc., are already in the hands of specialists, and with that subject also it has not seemed worth while to deal. But it is earnestly recommended that the surgeon should so familiarize himself with the appearance of skiagraphs, with their distortions, with the relative values of their shadows and outlines, as to be himself the judge of their teachings, and not depend upon the interpretation of others who may lack the wide experience with surgical injury, and disease necessary for the correct reading of these pictures.

THERAPEUTICS & PHARMACOLOGY.

Exclusive Soup Diet and Rectal Irrigations in Typhoid Fever.

BASED on his statements upon a personal experience of one hundred and fifty-three cases in private and hospital practice during the last ten years, A. SIEBERT gives the following as the results of this mode of treatment: (1) Delirium, headache, insomnia, nausea, vomiting, and tympanites usually disappeared within forty-eight hours of treatment. (2) Tympanites, nausea, and vomiting never developed in any patient, even when complicating pneumonia was present. (3) The fur on the tongue disappeared within a few days. (4) Appetite came frequently on the fourth day of treatment, even when the thermometer registered 102° to 103° F. (5) Even excessive diarrhoea (fifteen to twenty-five daily stools) disappeared invariably within the first week of treatment. (6) In all uncomplicated cases the temperature began to decline within twenty-four to forty-eight hours after the beginning of treatment, and invariably would reach the normal figure within ten to twelve days. (7) In cases complicated by pneumonia, nephritis, or plebitis when treatment began, the temperature usually remained in accord with the inflammatory conditions found until these also disappeared; while the cerebral, gastric, and intestinal disturbances usually subsided as rapidly in the uncomplicated cases, excepting anorexia. (8) Complications, when not present at the start, were very rare, and then usually developed within the first two days. (9) Intestinal hemorrhage was noticed in three cases, none ending fatally. Perforation did not occur. Five feedings were given during the day. After an initial purge the patients seemed to do as well for forty-eight hours on cold water alone as on any kind of food. Then soups were given made of barley, oatmeal, rice, and peas, strained and well salted and peppered. Two days later lentil soup and the yolk of a fresh egg were added to the oatmeal, rice, and barley soups. An adult was allowed half a pint of two kinds of soup alternating every three hours. Five to fifteen drops of dilute hydrochloric acid were given before each meal unless hyperacidity prevailed, but no other medicine. Cold water was allowed *ad libitum*.—*North western Lancet*.

For Locomotor Ataxia.

DR. S. LEDUC, Professor of Medicine in the School of Medicine at Nantes (*Gazette médicale de Nantes*), basing his practice on the theory that "the syphilitic origin of locomotor ataxia is scarcely contested to-day, for a past history of syphilis is found in nearly all ataxia," has injected daily into the muscles of the patient's thigh two grammes (about thirty minims) of the following solution:—

R	Corrosive sublimate	} each 3 grains.
	Recrystallized sodium chlorite	
	Distilled water	
M.		

It is said that an amelioration was at once manifest. Treatment was continued for periods of three weeks, followed by remissions of fifteen days. Six years from the commencement of the treatment the patient has lost the knee-jerk, and, though some lightning pains persist, he walks well, even at night, and leads a very active life.

For Varicose Veins.

R	Barii chloridi	2
	Aque destil	...	q.s. ut ft. sol.	
	Lanolini	60
	Ol. amygdalis dulc.	1

M. S. Use three times daily with friction, where blue veins shine through the skin.

—ALEX. RIXA.

For Pruritus Ani.

R	Fluid extract of hamamelis	1
	Fluid extract of ergot	2
	Fluid extract of hydrastis	2
	Compound tincture of benzoin	2
	Carbolized olive or linseed oil (5 per cent.)	1
M.	S. Shake well and inject from one to three drachms daily.			

Correspondence.

IN DEFENCE OF CIVIL ASSISTANT SURGEONS.

(Concluded from last issue.)

TO THE EDITOR, "INDIAN MEDICAL RECORD."

CHARGES OF JAILS.

Sir,—Colonel Sahib states that Indian officers as a rule fail to enforce discipline. There is no doubt that as disciplinarians European officers are superior; but the reason why Indian officers fail is simply that they are not properly trained. When, *after proper training*, they have worked satisfactorily in the highest offices in all departments of Government, it may be reasonably assumed that they will make good Jail Superintendents as well, if only they are given opportunities for training themselves. Deputy Magistrates fail, because, as has already been stated, the work is forced on them, and knowing that it is only temporary, and not strictly departmental, and therefore carrying little responsibility, they take no interest in it, and do not care to be strict in their dealings with the jail subordinates. Of course this is culpable neglect; but it is the inevitable result of the system. Let Assistant Surgeons be put in charge. To them the work will be departmental, and they will be bound to pay proper attention to it. Let them know that their jail administration will affect their prospects quite as much as their medical work. Let them actually do the work so that they may feel the responsibility. Let incompetent men be summarily dealt with, and in a short time their defects will disappear. It is not one's nationality that makes one a good disciplinarian and administrator—it is education and training.

PLACING OF CIVIL ASSISTANT SURGEONS UNDER MILITARY ASSISTANT SURGEONS.

"Every Civil Assistant Surgeon, whether from Calcutta, Bombay, the Punjab, or elsewhere," may not be better than the "Military Officer." As I have said above, there are competent and incompetent men in all services. There are men among Civil Assistant Surgeons who are unfit to be compounders, and there are men among Military Assistant Surgeons who are in every way as desirable as one could wish, and *vice versa*; but judging from the ordinary standards of comparison, there can be no doubt that, as a rule, taking everything into consideration, Civil Assistant Surgeons are better educated than their military namesakes. Colonel Sahib says that the former cannot express themselves in ordinary understandable English. Whether this is a fact or not, especially with reference to the Assistant Surgeons of the present day, I shall leave your readers to judge. To my mind, though on account of the fact that their mother-tongue is English, Military Assistant Surgeons can usually express themselves with greater facility if the language actually written and spoken by them be compared with that of Civil Assistant Surgeons—in point of grammar, etc., there will not be much difference. As regards professional qualifications, all India knows that in the ranks of *locally educated* Civil Assistant Surgeons there are men who have admittedly risen to the top of the professional ladder, and who, as practising physicians and surgeons, are second to none; while among Military Assistant Surgeons (excepting those who have had a subsequent education in Britain and have become members of the I. M. S.), in spite of "professional departmental and military experience," and the fact that only "selected" men are put in civil medical charge, it would be hard, if at all possible, to find even one with anything like a professional reputation.

To say that want of means prevents the Military Assistant Surgeon from prosecuting his studies through the local Universities, that he is a "more intelligent and better man," and that "in the end it is his thorough know-

ledge of medicine, surgery and midwifery which has manifestly led him forward," are to put forward arguments which, to an impartial observer, must appear hopelessly lame. Military medical pupils study for four years at Government expense. They can easily be made to study one year more and pass either the L.M.S. or the M.B. examination. In view of the fact that their mother-tongue is English, and in accordance with the practice in other departments of Government, the condition of passing the F.A. need not be compulsory. The present competitive examination for admission into the medical colleges may be considered sufficient, or its standard slightly raised. As a matter of fact, the real reasons for not requiring them to pass the University tests are: (1) That men with superior qualifications are not considered necessary, as Military Assistant Surgeons do the same work in British regiments which Hospital Assistants do in Indian regiments, and are intended to be officials of the same type as the latter; and (2) that it is feared that if the University test be made compulsory, the number of men required will not be able to pass it. Again, as everybody knows, it is not because they are more intelligent men, nor because they have better professional knowledge, that they have preference as regards Civil Surgeoncies. The factors which lead them forward are colour (if the authorities *would* only get colour-blind, how many anomalies would stop!), "imperial considerations," "war purposes," and so on. Their actual inferiority in rank and education has often been admitted by Government itself (G. O. G. G. No. 550, dated 15th June 1868, paragraph 469). Let the Government give them Civil Surgeoncies if it has reasons for doing so, or if it is "disposed" to favouritism; but why unnecessarily add insult to injury by putting them over the heads of Civil Assistant Surgeons in the same district? If they have superior or equal British or Indian degrees, nobody objects; if not, put only Hospital Assistants under them, and there the matter ends. Under the present system not only Civil Assistant Surgeons with Indian degrees, but even those holding British degrees, can be put under a common diplomat Military Assistant Surgeon, which is simply preposterous. Imagine a D. M. C. C. sitting in judgment over the diagnosis and treatment and reporting on the professional attainments of men at whose feet he might sit for years. Though it is true that only "selected" men are put in civil medical charge, but as these come to the Civil Department after a long term of grinding subordination, during which they have to do bottle-washing with eyes and ears closed, they make very little progress as practical physicians and surgeons. Besides, in military hospitals the diseases met with are not so various as in civil hospitals, and it is an admitted fact that an officer in civil practice is, as a rule, a better all-round practitioner than one in military practice. In stations where a Civil Surgeon is available, people seldom call in a purely military surgeon. The Military Assistant Surgeons who are "selected" for civil employment are consequently little better than "old fossils of metamorphosed apothecaries," and the records of their actual professional work in civil hospitals prove this.

Colonel Sahib says that "there are very very few (Military Assistant Surgeons) who would not challenge TOMTIT, M. B., to sit with them unprepared for an examination in surgery, medicine and midwifery." We live to learn,—and I have lived to learn that an officer of the I. M. S. thinks it consistent with dignity and culture to indulge in personalities of this sort; but that, of course, is another story. Leaving my unworthy self aside—for I am but a poor little bird—I gladly accept the challenge on behalf of Civil Assistant Surgeons; but if Colonel Sahib has so poor an opinion of Indian intellect, and is so sure of an easy victory, I might perhaps be permitted to ask how it is that Indian youths are so feared that they are not even permitted to compete for the Military Assistant Surgeon's service (though, of course, only Hospital Assistants

would care to do it if allowed), and why Colonel Sahib's brother officers are so frightened by the very mention of a simultaneous I.M.S. examination? Prepared or unprepared, let Indians have but a fair chance in open competition (make your standard what you will), and they will cheerfully abide by the result. Military Assistant Surgeons may challenge, but if an examination were really to be held, neither they nor the Government would be inclined to repeat the experiment.

As to whether the title of "Assistant Surgeon" has been deservedly gained or not, there will always be two opinions until "Military" Assistant Surgeons pass the same professional examinations as real Assistant Surgeons do.

ABOLITION OF SEPTENNIAL EXAMINATIONS.

Granting, for argument's sake, that what "LIEUT.-COL., I.M.S." states is true, what good do these examinations do? He himself says that "not till the examination is nigh will the Civil Assistant Surgeon read up his professional books," and that "once through the ordeal, all interest in further attainments is gone, and he leans back in apathy." Do the examinations then really improve his professional knowledge, and is his actual professional work better after he has passed these? Colonel Sahib's own remarks point out that the reply is in the negative. As regards the "callousness" of which he complains, it is simply due to the fact that, as stated above, a Civil Assistant Surgeon, as soon as he enters service, "finds too late" that his prospects depend not upon honesty, hard-work and professional ability, but upon *salaams*, *dalees*, *muzzurs*, manufacture of figures, and so on. His professional work may be ever so good, he may do specially meritorious plague and famine service, but for him there is no special promotion which, under similar circumstances, is given to officers in all other departments of Government—he must pass the inevitable septennial. On the other hand, he may be a mere *salaaming* and *dalee*-giving machine and incompetent, otherwise he has only to pass the septennial "with the help of a few aids," and he gets the higher grade far more easily than his able and hard-working colleague, and, if anything, a better station too; for there is nothing which kowtowing cannot achieve. Besides, what is the use of sending elaborate annual confidential reports if the septennial must be the criterion of fitness for promotion? And if Assistant Surgeons are really so ignorant and callous as regards professional attainments as Colonel Sahib says, how is it that in the majority of cases Civil Surgeons make favourable remarks annually regarding their abilities? Is it because ability is judged by *salaams*, or are the Assistant Surgeons really not so bad after all? I repeat that these examinations are not only useless, but positively injurious, and that the present promotion rules are the principal causes of apathy and callousness.

ASSISTANT SURGEONS SHOULD NOT BE REQUIRED TO COMPOUND PRESCRIPTIONS CONTAINING POISONS.

The main question is not whether compounding prescriptions is or is not *infra dig*, but whether it is possible to actually carry out the orders contained in the circular. As I have said in my previous letter, almost every prescription contains some poison or other, and if the instructions laid down were to be complied with, the Assistant Surgeon or Hospital Assistant in charge of a dispensary would have practically to dispense all prescriptions (and these would not be a few) with his own hands, while the compounders would have nothing to do. I agree with Colonel Sahib in thinking that the Assistant Surgeon should exercise strict supervision. I have myself suggested this. But I submit that it is absurd to expect him to compound prescriptions personally as required by the circular. As a matter of fact, the authorities have already seen the utter absurdity of the thing, and have modified the order. Now, stock prescriptions may be dispensed

by the compounders under the supervision of the officer in charge, and only other written prescriptions need be compounded by the latter. But in actual practice even this cannot be done. An Assistant Surgeon goes out at 11 A.M. after his hospital work is over, and does not return until 4 P.M. He is permitted to do this, because he is not a whole-time officer, and is allowed to do private practice. The Civil Surgeon in the meantime sends some urgent prescription containing poisons. Are these to remain undispensed till the Assistant Surgeon returns? Common sense says that the order cannot be carried out in any case. It is now two years since the circular was issued, and all this time it has simply been reposing in the files. Why not give it a quieter and more permanent resting-place in the W. P. B.? To my mind, merely on account of the Delhi poisoning case, there was no necessity whatever for altering the previous rule, because the large majority of people in big cities buy their medicines from private firms, and do not, and cannot, get these dispensed by Assistant Surgeons and Hospital Assistants; but if the Government wishes to be so particular, it should be prepared to spend a little more, abolish the compounder class, and appoint Hospital Assistants instead, though, for the matter of that, mistakes will occasionally occur, even if I.M.S. officers themselves turn compounders.

Yours, &c.,

TOMTIT, M.B.

THE I.M.S. IN DIFFICULTIES: WHY NOT USE LOCAL MEN.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—With reference to the proposal which has been recently sanctioned by Government to temporarily employ twenty private medical practitioners to relieve the overworked officers of the Indian Medical Service, it is not clearly stated whether they will be put on military or civil duties. Evidently they will be placed in charge of civil stations. Nobody will question the necessity of making some temporary arrangement for relieving the extra strain put on the Indian Medical Service on account of famine, plague and war. But to employ private practitioners to hold charge of civil stations will be an injustice both to the Civil and Military Assistant Surgeons, whose fitness for such posts is beyond dispute. Assistant Surgeons have on many occasions held charge of civil stations, with satisfaction to Government. It might be urged, however, that Assistant Surgeons cannot be placed in charge of large and important districts, but these appointments may be filled up by the available number of European medical officers, and the smaller districts may be placed in charge of the former. Assistant Surgeons of tried merit and ability should be selected for filling up temporary vacancies. It is rather unfair to employ outsiders when competent men already in the service are available. The pay of the private practitioners will be from Rs. 500 to 600 per mensem, whereas the cost of employing Assistant Surgeons to do the same work would be much less.

It is a matter of regret that even the number of appointments of Assistant Surgeons in permanent medical charge of districts in several provinces, still falls short of that sanctioned by Government. In Bengal seven Civil Surgeoncies have been sanctioned for Assistant Surgeons, but four only have been given to them.

Yours, &c.,

JUSTICE.

Government Medical Gazettes.

BENGAL.

Asst. Surgn. Kunja Lal Sanyal, Teacher of Medicine, Midwifery and Physiology, Dacca Med. School, is apptd., on return from leave, to act at the Chapra Dispy., during the absence, on deputation, of Asst. Surgn. Uma Charan Roy.

Asst. Surgn. Khirode Chandra Roy, of the Uluberiah Subdivn. and Dispy., Howrah, is apptd., on return from leave, to act at the Barisal Dispy., in the Backergunge dist., during the absence, on leave, of Asst. Surgn. Badrika Nath Mukerjee.

Asst. Surgn. Sarat Chandra Sur did supy. duty at the Med. Coll. Hosp., Calcutta, from the 18th Jan. 1901 to the 1st Feb. 1901.

Asst. Surgn. Badrika Nath Mukerjee, of the Barisal Dispy. on leave, is apptd. to act at the Jamui Subdivn. and Dispy., in the Monghyr dist., during the absence, on leave, of Asst. Surgn. Bhola Nath Pal.

Senior Asst. Surgn. Bola Nath Pal, in med. ch. of the Jamui Subdivn. and Dispy., in the Monghyr dist., is allowed privilege leave for 2 months and 17 days.

Asst. Surgn. Nobin Chunder Dutt is apptd., from the 15th Oct. 1900, to have med. ch. of the Palamau dist., vice Asst. Surgn. Rai Raj Mohan Banerjee, Bahadur, retired, but will continue to act at Noakhali.

Asst. Surgn. Kunja Lal Sanyal is promoted to the senior grade from the 15th Oct. 1900, vice Asst. Surgn. Nobin Chunder Dutt.

The undermentioned Asst. Surgns. of the first grade are promoted to the senior grade :—

Asst. Surgn. Kasi Nath Ghosh; Asst. Surgn. Behari Lal Pal; Asst. Surgn. Durga Nanda Sen.

Capt. J. T. Calvert, I.M.S., is apptd. to act as Civil Surgn. of Chittagong, during the absence, on deputation, of Maj. D. M. Moir, I.M.S.

Maj. E. H. Brown, I.M.S., Offg. Civil Surgn. of the 24-Perganna, is confirmed in that appt.

Capt. E. A. R. Newman, I.M.S., is apptd. to be Civil Surgn. of Mymensingh, vice Maj. E. H. Brown, I.M.S., transferred, but will continue to be on tempy. mily. duty.

BOMBAY.

Hosp. Asst. Chellaram Tillumal, in ch. Dispy., Garhi Yasin, privilege leave for three months from the 18th Sept. 1900.

Asst. Surgn. W. B. George, I. S. M. D., privilege leave from 25th to 31st Aug. 1900.

Hosp. Asst. Shaik Jamal Hussein was attached to the Alia Island Quarantine Hosp. from 18th to 22nd Oct. 1900.

The undermentioned having passed their final-exam. in the Byramji Jijibhoy Med. Schools, Poona and Ahmedabad, and the Med. School, Hyderabad, are admitted into the service as Hosp. Assts., Civil Dept., from 3rd Sept. 1900. They will bear gen. numbers marked against their names and are placed on gen. duty at the stns. mentioned opposite their names from 3rd Sept. 1900 :—

Kavaji Bamanji, Ahmedabad; Radhakishin Tahilram, Hyderabad; Wamon Ambaji Warty, Poona; Munjunath Timappa Sirsikar, Poona; Begraj Chandumal, Hyderabad; Manukh Ranobhed, Ahmedabad; Luxumon Murari Sali, Poona; Litarum Nenumal, Hyderabad; Vithal Mahalapa Khawadkone, Poona; Shaik Usman walad Shaik Mahomed Hussein, Poona; Moro Pandurang Kolatkar, Poona; Buldevsing Vajesingh, Ahmedabad; Jamiatram Pransukhram, Ahmedabad; Shivandas Bachomal, Hyderabad; Vadilal Jannadas, Ahmedabad; Wasudev Arjun Sawant, Poona.

The undermentioned Hosp. Assts. who were admitted into the Dept. as Hosp. Assts. as a tempy. measure, and whose names were notified, are apptd. Third Class Hosp. Assts. on the permanent estab. from 24th Oct. 1900 to complete estab. :—

Narayan Vitboji Sawant; Sitaram Balwant; Ibrahim walad Ameen; Dhondu Krishna; Anant Krishna Salghar.

The undermentioned having passed his final exam. in the Med. School, Ahmedabad, is admitted into the service as Third Class Hosp. Asst., Civil Dept., from 6th Nov. 1900, vice Hosp. Asst. Krishnaji Ramchander, dismissed from the service :—

Gorishanker Liladher.

The undermentioned have passed the exam. and are admitted into the Byramji Jijibhoy Med. School, Poona, from 1st Nov. 1900 :—

Civil Medical Pupils.

Balwant Ramji Marathe; Vishwanath Govind Kulkarni; Shivbasappa Shidappa; Lalasing Dhanasing; Mohomed Ibrahimkhan; Anandras Shamrao; Ganpat Baburao Duvi; Sayad Budhain walad Sayed Hosein.

Native Military Pupils.

Udhav Sakharam Shendge; Shaik Husein Abdul Nabi; Bapu Ramchandra; Govind Dinkar Paranjpe; Gajanan Narayan; Krishnaji Govind Lobokare; Yeshwant Kishnaji Bhide; Kaabinath Balwant Bohoni; Shaligram Dinker Joshi; Kashinath Ramchandra; Keshav Wamon Joshi; Wadudeo Arimuta; Vasudev Banda.

Stipendiary Pupils.

Baghwandra Narayensao; Baghunath Vishwanath; Kashinath; Damodher Kulkarni; Damodher Bhasker; Hari Gopal Gadgil.

Paying Pupils.

Keshav Narayan; Dhondu Narayan.

State Pupils.

Sadashiv Ramchandra; Balobin Rawji; Dattatraya Chintamon; Maheshwar Krishna; Dattatraya Vayajpath.

The undermentioned Third Class Hosp. Assts. are dismissed from the service :—

Krishnaji Ramchander; Vishnu Balwant Bhide.

BURMA

Hosp. Asst. Ramprasad Sinha held ch. of addnl. duties at the Civil Hosp., Mogaung, Myitkyina dist., from the 29th Nov. to the 9th Dec. 1900, vice Hosp. Asst. M. A. Aubaranam Pillay on other duty.

Hosp. Asst. Lukmi Dass relinquished ch. at the Police Hosp., Mogaung, on the 5th Dec. 1900 and assumed ch. of his duties with the Kamalg Escort on the same date.

Hosp. Asst. Mahomed Haniff relinquished ch. of his duties at the Police Hosp., Kindat, Upper Chindwin dist., on the 29th Nov. 1900 and assumed ch. at the Outpost Hosp., Thamanthi, Upper Chindwin dist., on the 11th Dec. 1900.

Hosp. Asst. M. A. Aubaranam Pillay relinquished ch. of his duties at the Outpost Hosp., Kamalg, Myitkyina dist., on the 8th Dec. 1900 and assumed ch. at the Civil Hosp., Mogaung, on the 9th Dec. 1900.

Hosp. Asst. M. A. Aubaranam Pillay made over, and Hosp. Asst. J. P. S. Mullins assumed, ch. of addnl. duties at the Civil Hosp., Kamalg, Myitkyina dist., on the 8th Dec. 1900.

Hosp. Asst. Rattan Chand. on return from India, assumed ch. at the Gen. Hosp., Rangoon, on the 15th Dec. 1900 as a supy.

Hosp. Asst. Rattan Chand relinquished ch. at the Gen. Hosp., Rangoon, on the 18th Dec. 1900 and assumed ch. at the Ry. Dispy., Wuntho, Katha dist., on the 23rd Dec. 1900.

Hosp. Asst. Shaik Abdul Aziz, on return from leave, assumed ch. at the Gen. Hosp., Rangoon, on the 14th Dec. 1900, as a supy.

Hosp. Asst. Shaik Abdul Aziz, on transfer to the Chin Hills, relinquished ch. of his duties at the Gen. Hosp., Rangoon, on the 18th Dec. 1900.

Hosp. Asst. J. P. S. Mullins, on proceeding to Myitkyina to give med. evidence, relinquished ch. at the Outpost Hosp., Kamalng, Myitkyina dist., on the 30th Nov. 1900, and on return from the same assumed ch. at the Outpost Hosp., Kamalng, Myitkyina dist., on the 8th Dec. 1900.

PUNJAB.

Lieut.-Col. J. Clarke, M.D., I. M. S., made over ch. of the duties of Supdt. of the Sialkot Jail to Sayad Wali Shah, Extra Asst. Commr., on the 19th Nov. 1900.

Sayad Wali Shah, Extra Asst. Commr., made over ch. of the duties of Supdt. of the Sialkot Jail to Asst. Surgn. Khazan Chand on the 24th Nov. 1900.

Lieut. J. T. Weston, M.D., Senior Asst. Surgn., made over charge of the duties of Supdt. of the Hissar Jail to Khawaja Tasadduq Hussain, B.A., Extra Asst. Commr., on the 29th Dec. 1900.

Khawaja Tasadduq Hussain, B.A., Extra Asst. Commr., made over ch. of the duties of Supdt. of the Hissar Jail to Lieut. J. T. Weston, M.D., Senior Asst. Surgn., on the 15th Jan. 1901.

Hosp. Asst. Firoze Din, doing gen. duty at Hissar, was granted one month's privilege leave from the 17th Jan. 1901.

On transfer from Jullundur, Asst. Surgn. Udai Bhan. Imperial List, was placed on gen. duty at the Pind Dadan Khan Dispy., Jhelum Dist., on 15th Dec. 1900.

On being relieved of the ch. of the Gujranwala Dispy. Asst. Surgn. Balio Singh was placed on special plague duty, in the Jullundur and Hoshiarpur Dist., from the 21st Jan. 1901.

Asst. Surgn. Hardial Singh was apptd., as a tempy. measure to the Hoshiarpur Civil Hosp. from the 18th Jan. 1901, *vice* Asst. Surgn. Harnarain, granted privilege leave for one month from that date.

Capt. G. M. C. Smith, I. M. S., assumed ch. of the Civil Medical duties of the Kangra Dist. in addn. to his Mil. duties, on the 14th Jan. 1901, relieving Lieut.-Col. W. E. Griffiths, I. M. S.

CENTRAL PROVINCES.

Hosp. Asst. Basant Rae, on being relieved of the ch. of the Rankhet Dispy., to the ch. of the Crosthwaite Hosp., Naini Tal, as a tempy. measure.

Hosp. Asst. Muhammad Roeban, attached to the Mahron Dispy. in the Jhansi dist., held ch. of the Lalitpur Dispy., from 6th to 14th Jan. 1901.

Civil Asst. Surgn. Nogendra Nath Dass, from Plague duty, Jhansi, to that in the Ballia dist.

Capt. P. F. Chapman, I. M. S., who services have been permanently placed at the disposal of the Chief Comr. Central Prov., by the Govt. of India, is confirmed as Civil Surgn., Chhindwara, from the 15th April 1900, but will continue as Civil Surgn., Seoni.

Major J. O. Pinto, L. M. S., whose services have been permanently placed at the disposal of the Chief Comr. Central Prov., by the Govt. of India, is confirmed as Civil Surgn. Balaghat, from the 15th April 1900, but will continue as Civil Surgn., Chhindwara.

On being relieved by Major H. E. Banatvala, I. M. S., 2nd grade Civil Asst. Surgn. Dalip Singh, in tempy. civil medical ch. of the Nimar Dist., is directed to do duty under the orders of the Civil Surgeon, Hoshangabad.

One month's leave without pay is granted to Civil Hosp. Asst. Jotindranath Ghose, on general duty at Nagpur. Civil Hosp. Asst. Kehiroda Kumar Ghose is directed to do duty under the orders of the Civil Med. Offr., Bhandara.

Second Class Civil Hosp. Asst. Amin-ud-din, attached to the Jail and Police Hosp., Khandwa, is granted privilege leave for three months from the date he is permitted to avail himself of it.

Civil Hosp. Asst. Vithal Raghoba Lande, on gen. duty at Nagpur, is apptd. to the Jail and Police Hosp., Khandwa, during the absence on leave of Amin-ud-din.

N.-W. P. OUDH.

The services of Major L. J. Pisani, F.R.C.S., I.M.S. (Bengal), are replaced at the disposal of the Govt. of the N.-W. P. and Oudh.

The services of Capt. E. J. Morgan, M.B., I.M.S. (Bengal), are replaced tempy. at the disposal of the Govt. of the N.-W. P. and Oudh.

Civil Asst. Surgn. Kedar Nath Basu, attached to the Sadr Dispy., Shahjahanpur, to hold ch. of the civil med. duties of that dist., in addn. to his own duties, from the 16th Jan. 1901.

Major L. J. Pisani, I.M.S., whose services have been replaced at the disposal of this Govt. by the Govt. of India, to be Civil Surgn. of Budana.

Capt. E. J. Morgan, I.M.S., whose services have been tempy. replaced at the disposal of this Govt. by the Govt. of India, to officiate as Civil Surgn., Banda.

Civil Asst. Surgn. Munna Lal, on being relieved from the Civil Med. Ch. of Banda to that of Jalaun.

Lieut.-Col. E. S. Brander, I.M.S., Civil Surgn., from Furrakhabad to Shahjahanpur.

DOMESTIC OCCURRENCES.

[The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.]

BIRTH.

BROCKMAN.—On the 31st January 1901, at Southampton, England, the wife of Captain V. G. Drake-Brockman, I.M.S., of a son.

NOTICES TO CORRESPONDENTS.

B. B. B. writes:—"My girl-wife, aged about 14 years, is in family way for six months. She was vaccinated once while her age was about 2 or 3 years. Now a virulent type of small-pox is raging in our quarters. I intend to revaccinate all the members of my family. Will you kindly advise me whether I can revaccinate my wife in this stage of her pregnancy?"—(Most certainly, vaccinate her.—Ed., I.M.R.)

D. G. (Bangalore)—The delay in acting on the reorganisation scheme sanctioned for Military Hospital Assistants as they affect men in Madras is a real grievance.

H. C. E. (Bombay)—We think you might gain admission to the Calcutta College if you could procure certificates of your attendance on lectures, etc., from Bombay.

"John Brown."—If the writer signing himself thus would kindly make himself known to us *confidentially*, we might be in a position to publish his communications.

M. M. (Chandauli)—Mitchell Bruce and Whitla are two good works on Materia Medica.

B. A. N. (Delhi)—The subject of your letter has already been dealt with in our correspondence columns.

A. P. (Bombay)—The pamphlet is good in its way, but the methods described need modernising.

H. E. S. (Penang)—Many thanks. We have dealt with your letter.

A. S. N. (Rupupa)—You will find all needed information regarding the I. M. A. and its Provident Fund in the *Record*.

C. P. (Madras)—Your papers are appreciated.

M. L. (Ulubaria)—Medical practice in India requires State control. American bogus diploma-holders would vanish once a Registration Act came into force.

B. M. S. (Calcutta)—Thanks for your interesting paper.

R. S. P. (Bhavani)—You will find all the information you require about British diplomas in the Medical Directory of the Indian Empire.

S. M. V. (Lucknow)—Try the intra-uterine stem.

ORIGINAL ARTICLES.

EXPERIENCES WITH THE MEDICAL DEPARTMENT OF THE ARMY IN THE SOUTH AFRICAN WAR.*

By JOHN CHIEME, F.R.C.S., EDIN.,

Professor of Surgery in the University of Edinburgh.

In bringing before the Society my experience in South Africa, I must keep in mind that my stay there was divided into two distinct periods, from the beginning of April until the end of June, from the end of June till the end of August; from Capetown to Norval's Pont in the first period, from Norval's Pont back to Capetown in the second period. At first I was simply a consultant, who advised in individual cases; afterwards the allegations regarding the Army Medical Department had reached Africa, and it was evident that other questions would necessarily occupy my attention.

These questions are still *sub judice*, and cannot yet be discussed. Whatever may be the verdict of the Commission, every one must allow that the question of Army Medical reform is only a subsection of wider question of Army reform.

I purpose saying a few words regarding the lessons which I have learned in the hospitals in South Africa. I will speak of these lessons under the following heads:—*Ambulance, Anaesthesia, X-rays, Hospital trains and ships, Bullet wounds, Injuries of the head, Injuries of blood-vessels, Injuries of thorax and abdomen, Medical cases, Sanitation, Burning vs. Burying*, and then close with a word on the *Work of the Civil Surgeon in South Africa*.

The four great hospitals in the neighbourhood of Capetown were Wynberg No. 1, Wynberg No. 2, Rondebosch No. 3, and Woodstock No. 4. Much has been said about Woodstock. It is an old building near Capetown, lying on the shore, and, like all old buildings in South Africa, it was infested at one time with animal parasites, which gave rise to much discomfort. On my second visit great improvement had taken place in this particular. I never noticed any smell from the town drains, which opened into the bay in the vicinity of the hospital. The drain for surface water was a short one. The drain for sewerage opened 300 yards from the shore, and the current carried the dejects away from the hospital, and, judging from the excellent results of the surgical cases which I saw there, I cannot look upon the hospital as an unhealthy one.

The dejects from the hospital, after being mixed with izal, were buried in a trench on the shore. I examined these trenches, and found no smell whatever.

My time was principally spent in the Wynberg and Rondebosch Hospitals, two days a week to each hospital. Both were on excellent hospital sites.

Let me first say a word regarding the conveyance of the soldiers from the trains to the hospitals. As I lived at Wynberg, I saw them arrive by train, and I saw them immediately after admission to the hospital. Every one must clearly differentiate between hospital trains and

ordinary trains carrying invalids. In the former, the soldiers were most comfortable: in the latter, it was very often the reverse. I am fully satisfied that in the future some form of portable cooking-stove must be carried in these ordinary trains, by means of which simple food may be cooked for the soldiers. You cannot trust for a supply of food at the stopping places. It was often very sad to see how worn and weary the poor fellows were on their arrival. Much was done for them at the Wynberg Station by good, kind ladies, who were always in attendance. They must, if possible, in future campaigns be well fed on the journey.

As regards their conveyance from the trains to the hospital, at Wynberg this was done in ambulance carts. On a smooth road an ambulance cart is fairly comfortable; but, in my opinion, the McCormack-Brook ambulance litters are certainly more comfortable than ambulance carts, and I think it will be a question of the future if these litters should not take the place of carts in the conveyance of patients from trains to hospitals. I came across a member of the Imperial Yeomanry who had been in both as an injured man, and, in his opinion, there was no comparison in the relative comforts. We see the same thing in civil life—the greater comfort of the litter as compared with the waggon. These litters were on Rickshaw wheels, with rubber tyres, and worked most smoothly.

A question for the future will arise, can any improvement be made on ambulance waggons for the removal of patients from the battlefield to the nearest hospital? The Boers used, as a rule, waggonettes and Cape carts.

I have frequently heard our soldiers say that they would rather travel in an ox waggon than in an ambulance cart. Surely some improvement could be made. Possibly an open competition would teach us some lessons as to the best form of ambulance waggons. The essentials are strength, easy turning, easy motion, and the patients easily reached by the attendant. The stage-coaches in South Africa are hung on leather. No doubt they are the results of evolution and the survival of the fittest; and many think that the old-fashioned leather springs are worthy of trial for ambulance purposes. The swing of the carriage must not be too great, for fear of sickness analogous to sea-sickness.

Anaesthesia.—Chloroform was the favourite drug. Ether and A.C.E. were in occasional use. I never saw any trouble with any form of anæsthetic. A little struggling, but no sickness at the time, and very little afterwards. Can the sickness in civil life be a nervous condition which does not hold good amongst soldiers in time of war? I am fully satisfied that the soldier accepts without demur any decision which is come to as regards his treatment. He is contented and asks no questions. "All right, I am ready," is his answer. He reminds me of the condition of mind in a patient suffering from shock—not taking much interest in his own case. I speak of the soldiers that I saw at the base, long after their injuries had been received; they seemed still to be suffering from chronic shock, if I might use the term. Their nervous system had received at the time of the accident a shock from which they had not recovered. I can only

* An Address delivered to the Edinburgh Medico-Chirurgical Society.

recall one case of a soldier who refused to be operated upon. How different it would have been in civil life. How often is your advice not taken, possibly because the civil patient has a larger choice of doctors, and goes from one to another, seeking advice until he gets that which agrees with his own or his friends' view of the case. The soldier is alone, has no meddling friends, is trained to obedience, and looks on the doctor as one whom he can trust. The other day Dr. LORANS, Medical Officer of Health for Mauritius, was in Edinburgh on a holiday. When I spoke to him of the ready acceptance of the soldier when operative treatment was suggested, of the ease with which chloroform was taken, and the absence of all anxiety during its administration, he told me that he was much struck by both of these things happening after the dreadful typhoon which visited Mauritius in April 1892. In consequence of it, many operations were necessary on those who had been injured. The Indian population in island, in the times of quiet, raised many objections to operations. On this occasion every one was most amenable, and objections were made. The condition of the patients greatly facilitated the administration of chloroform.

The X-rays.—Great difficulties were often experienced in localising bullets in the spine and pelvis. In the limbs little difficulty arose. In the pelvis a rectal examination will sometimes localise a bullet when the x-rays have been found wanting. I am satisfied that the efficient use of the x-ray apparatus depends very much on the experience of the man who uses it. In some hospitals much want of trust, in others full belief; in the former, inexperienced operators; in the latter, capable fellows, who could localise a bullet without doubt or demur. MACKENZIE DAVIDSON's method gained most acceptance.

Another thing which was very evident in South Africa was the distinct division of patients into two great classes—those who were anxious to go home, those who wish to go back and fight. The first were all septic cases; the second aseptic ones. Dysentery is the disease which most takes the heart out of a man. In the hospitals I saw no one who had not a strong opinion one way or another.

Hospital trains and ships.—I am very anxious that my hearers should fully understand the great value of hospital trains and hospital ships. In Natal the absence of corridor carriages rendered the Princess CHRISTIAN's hospital train of much value. Most fortunately it was ready just in time to cross the Tugela and bring back the sick after the relief of Ladysmith. Colonel FORRESTER, educated in Edinburgh, was then in charge. Shortly afterwards he was seized with typhoid fever, which occasioned his death.

In Cape Colony there were four trains with every comfort; two of them under the care of Edinburgh men, Major SIMPSON and Captain FLEMING, D.S.O. The good that these trains did is incalculable. KIPLING has written of them. I wish his articles, which appeared in the *Cape Times* and in London papers, could be reprinted in a separate form. To my mind they gave the best idea of the true condition of affairs.

As regards the hospital ships, I had no experience of those fitted up at home, but I saw two of the sick ships fitted up in Durban, the *Lismore Castle* and the *Simla*, and I am sure nothing could be better. Every comfort and every convenience, and it is especially interesting to note that, as regards the Durban ships, they were fitted up by naval officers, with no special experience, assisted by Major MACCORMACK. I have heard it said that when these ships went home, they were the envy of the skilled artificers who had fitted up the hospital ships at home. Colonel GALLWEY, the energetic head of the Natal Medical Service, looked on these ships as base hospitals. They contained 1,660 beds, and were a great help in relieving the congestion in the hospitals on the lines of communication. When I mention Colonel GALLWEY's name, I cannot but recall the valuable work done by the Indian Bearer Company inaugurated by him. All spoke well of their bravery and gentleness.

It has to be remembered that the problem in Natal was a much easier one than that in Cape Colony—50,000 men as compared with 150,000; 200 miles of railway as compared with 1,000. These two factors alone made all the difference.

Bullet wounds.—A very interesting question was constantly raised; when a soldier was struck at a near range the wound was worse than when received at a distance. Between 200 and 400 yards a more ragged wound resulted than when the soldier was struck at 1,000 or 1,500 yards. Possibly the bullet is like a top: at first it spins round a centre, and then after a time it settles down into its true course. In Johannesburg I saw several cases of severe brain injuries, often very fatal. In one night three were admitted, and all died. I see in the papers that these injuries are explained by expanding or explosive bullets. Such bullets were undoubtedly found in the bandoliers, but I think the cases must be divided into two groups—first, those in which the bone and brain are severely injured and torn; second, those in which, with a comparatively small bone wound, the brain is much torn. In the first the injury is probably, if no shrapnel is being fired, due to expanding or explosive bullets. In the second the MAUSER bullet may be the cause when fired at a short range.

As regards the poisoning of bullets, I brought home some of the green-coated bullets, and Dr. HUGH MARSHALL, in the chemical laboratory, has kindly examined them, and given me the following interesting report:—

“EXAMINATION OF GREEN-COATED CARTRIDGES (MAUSER)
FROM MAFKING.

“The coating extends from near the tip of the bullet up on to the shoulder of the case. It has not been applied by dipping, but apparently by smearing the molten material backwards and forwards along the cartridge.

“The coating is fatty or waxy in appearance. Over the bullet it is of a uniform green colour and opaque, but over the case the colour is irregular, and the yellow colour of the brass is distinctly visible in small patches through the coating; when examined by means of a lens, the colouring matter is here seen to be in the form of small spots, distributed more or less thickly through a slightly coloured mass.

"When the coating over the bullet is carefully scraped off in very thin layers, it is at first found to be colourless, forming a white greasy powder. Some distance below the surface the green colouring is reached, continuing right down to the surface of the bullet.

"The colourless material melts at about 47° C., and is easily saponifiable by alkalies. It has a distinctly acid reaction.

"The green-coloured portions, when examined chemically, give well-marked copper reactions.

"The bullets in these cartridges are composed of an outer steel envelope, plated inside and out with an alloy consisting principally, if not entirely, of copper and nickel, and filled with a lead core.

"From the facts stated, it is evident that the green colouring matter was not originally present in the coating, but has been derived from the metal. Probably the cartridges were simply coated with suet or tallow for the purpose of lubricating the rifle barrel. In course of time the fatty acids originally present, and which would increase in quantity on keeping, have attacked the underlying metal, forming green-coloured copper salts which have gradually spread through towards the outer surface of the fatty material. Apparently the copper is more easily abstracted from the copper-nickel plating of the bullet than from the brass of the case.

"From the point of view of those against whom the ammunition is employed, there can be little difference between such coated cartridges and those which have not been so treated; from one cause or another, the coating is fairly certain to be completely removed before the bullet reaches its billet.

HUGH MARSHALL.

"University of Edinburgh, October 10, 1900."

Head injuries.—My experience of cerebral herniæ before I went to Africa was very unfortunate; cases rarely recovered. In Africa the majority of the cases that I saw were on a fair way to recovery, and in some the recovery was complete. The antiseptic treatment, in my opinion, could not fully account for it. Possibly it was the larger opening in the bone, because my experience has been that if a hernia appears at a comparatively small opening it goes on growing, and the best chance for the patient is to increase the size of the opening in the skull. The intracranial pressure acts like a wedge, and the larger the opening, the less the pressure. Dr. LOUIS IRVINE, a civil surgeon at Port Napier, Pietermaritzburg, spoke of the good results of formalin in cases of cerebral hernia. He used solutions varying in strength from 5 per cent. to 25 per cent. These solutions acted by drying up the mass, and were at the same time antiseptic.

I saw several cases of severe brain injury followed by recovery. At Wynberg, a patient, when lying on his abdomen, was struck by a bullet on the right temporal region, which passed downwards, forwards, and inwards into his mouth, through the hard palate opposite the right canine tooth. He made a good recovery. In Johannesburg I saw a man in whom a bullet passed

transversely across the brain in the frontal region without bad consequences. At Rondebosch I saw a very interesting case, in which a bullet was removed from the left temporal fossa above the base of the mastoid process. It had been localised by the x-rays. It entered the skull to the left of the middle line, passing through both occipital lobes. A right hemianopsia resulted. The curious thing about the bullet was that, when removed, the base of the bullet was next the bone, the apex of the bullet looking in the direction of the line of fire. I remember seeing at Woodstock a Boer prisoner who had lost by a shrapnel accident a large area of his skull. When I saw him the wound was healed, but the bone was not restored, and as he was a middle-aged man, there was little hope that ossific formation would take place. I suggested, in order to prevent injury to the pulsating brain, that he should wear a shield of Britannia metal. He smiled, and replied that "he had had enough of that metal."

Injuries of blood-vessels.—I saw several cases of arterio-venous aneurism in the South African hospitals. They occurred in the neck and extremities. Much improvement resulted from proximal ligation of the main artery, when the communication was between the carotid artery and internal jugular vein. In the thigh, ligation of the femoral artery did good. In the leg, the aneurism as a rule was laid open, and the artery and vein ligatured above and below the opening. As far as I could judge, the cases were more allied to aneurismal varix than varicose aneurism; but there was not the great dilatation of the vein which is commonly described in such cases. Possibly the cases were too recent, and the venous dilatation occurs at a later date. I had no opportunity of making a dissection of any of those cases of arterio-venous aneurism in the neck, but the improvement that took place after proximal ligation of the main artery, with the absence of any venous dilatation, made me wonder if the condition could be due to bruising of the artery and vein, and subsequent matting with constriction. No one could avoid noting the number of cases of painful neuritis from bruising of the nerve, the cases of neuritis due to adhesion of the nerves to bone after fracture, and the cases of neuritis due to splinters of bullets lodged in the nerve, without thinking that possibly the same thing might have occurred to arteries and veins lying side by side, and giving rise by matting and constriction to symptoms similar to those met with when there is a communication between the artery and the vein.

One case of arterio-venous aneurism in the neck made a deep impression on me. The bullet had passed through his neck from side to side, the track of the bullet passing behind the trachea and behind or through the œsophagus. There was a pulsating tumour low down in the neck immediately above the clavicle, so low down that nothing but distal ligation of the carotid could be attempted. He developed enteric fever, and was invalided home. I heard of him recently in Devonshire, jumping a 6-foot wall. No operation had been performed.

I may mention a strange coincidence in relation to arterio-venous aneurism. Two brother-officers in one

regiment were wounded in the same battle. In one the bullet entered on the right side, 2 inches below the angle of the jaw, the wound of exit, being at a corresponding point on the opposite side of the neck. In the other, the track of the bullet was the same, the course reversed. In both an arterio-venous aneurism developed near the wound of exit. They were taken off the field in the same ambulance, and brought down to Wynberg. Mr. MAKINS operated, ligaturing the common carotid in both cases, with very decided improvement. In false aneurisms the sac was laid open, and the artery tied above and below the bleeding point.

Injuries of thorax.—In lung injuries I was struck with the rarity with which the patient said that he spat blood at the time of the accident. Apparently the MAUSER or LEE-METFORD bullet passes through the lung, searing it and preventing hæmorrhage. On the other hand, it must be noted that in many cases there was hæmothorax probably from the intercostals, and most of the surgeons were agreed that if the blood was slowly absorbed, tapping assisted absorption, and there was also general agreement that a rise in temperature was the first indication that absorption had commenced. Possibly this rise is analogous to the rise we see for a day or two after an extensive operation, due to absorption of the products of metabolism. Empyæma as a result of lung injuries rarely occurred. I only saw four cases. I saw several cases of penetrating thoracic wounds in which, after careful examination of the apertures of entrance and exit, I could not but come to the conclusion that the bullet had traversed the heart. I can only express this as my opinion. I earnestly hope that a careful tabulation of all these cases will throw some light on the effects of the MAUSER on the viscera, lungs, intestines, heart. In all the cavities I saw wounds which, from my former experience, would have certainly proved fatal.

Abdominal injuries.—I had no opportunity of forming an opinion on the question of immediate operation in penetrating wounds of the abdomen. I can only say that I saw several cases in which complete recovery had taken place without operation. It was currently believed that the hungrier a man was, the less his risk in an abdominal wound. I saw one case at Kroonstad in which the wounded bowel had been excised, and I heard of another successful case in Natal. As in the lung, so in the intestine, apparently the MAUSER bullet makes so small a wound that neither bleeding nor extravasation occurred. I can explain the recoveries after penetrating wounds in the abdomen in no other way. I saw in Wynberg two very interesting cases of penetrating abdominal wounds, in which a large hæmatoma formed in the iliac fossa. In one, the abdomen was opened and the clot expressed; in the other, absorption took place.

In one case the bullet traversed both thoracic and abdominal cavities without evil consequences. It entered above the left clavicle, and was removed from SCARPA'S triangle on the right side.

After I left Wynberg, I was brought in contact with a new state of affairs. To a great extent, in Kimberley, Bloemfontein, and Kroonstad, almost entirely in Johan-

nesburg and Pretoria, the sick and wounded were in hotels, churches, and halls, and if there was free ventilation and the rooms were large, they made excellent hospitals, but tents and hospital huts are better than houses. In speaking to the students at the beginning of the session, I referred to what seemed to me a matter of very considerable importance. The purification of these buildings must be very thorough. Many South African friends expressed to me their fear of the coming year, and they anticipate a great outbreak of enteric in the near future. This will be a very serious affair, looking to the flood of emigrants, new to the country, who will rush north whenever they get the chance. I think there should be no delay in sending out the best incinerators, and compelling the authorities to burn the dejecta. Burying is common in Cape Colony, in the Orange River Colony, and Transvaal. In the three large hospitals in Natal, Estcourt, Mooi River, and Howick, the dejecta were burned. At Johannesburg I made a careful examination of the methods used in burying. I found all the Kaffirs who removed and buried the dejecta in good health, and in a very short time the earth in the trenches in which the burial had taken place resumes its normal appearance. Still I cannot help thinking that burning is infinitely preferable, and I trust that it will soon become general throughout South Africa. There should certainly be incinerators at all the railway stations to burn the dejecta from the hospital trains.

We will, I trust, hear from Dr. BOYD his experiences on typhoid and dysentery, but I may be allowed to say that phlebitis of the common femoral vein was a frequent complication in enteric, delaying recovery. I did not hear of any fatal results from it. Patients with typhoid died from exhaustion or hæmorrhage, rarely from perforation.

There is much difference of opinion as to the merits of typhoid inoculation. It will be some time before the results can be tabulated, because the medical sheets of the soldiers did not accompany them, and no definite data could be attained, more especially from those who were admitted into the hospital in a moribund condition.

There is a fever in the nomenclature of disease used in the army called "Simple Continued Fever." Many hold that it is aborted typhoid, and at Estcourt Hospital I was informed that five out of six cases reacted to the WIDAL test. Had these patients been inoculated for typhoid, and was the reaction due to the inoculation?

The WIDAL reaction test was not in use as a rule in the military hospitals. It is from the civil hospitals that we will hear regarding its value as a diagnostic.

As regards dysentery, I was struck with the great depression of spirits of the patient. The treatment by the free use of sulphate of magnesia, followed by ipecacuanha, was the favourite remedy. Dr. WATKINS PITCHEFORD, a civil surgeon at Estcourt, strongly recommended the use of ipecacuanha along with bismuth and chlorodyne in dysentery. He has described the treatment in the *British Medical Journal*, 10th November 1900. He used it on the suggestion of Dr. CROSSLAND, a civil surgeon on duty at Estcourt.

Abscess of the liver sometimes followed dysentery. Those who had most experience of this disease in India advocated posterior aspiration; then, if the pus was found, removal of a rib and free drainage. All dwelt on the importance of a very large drainage tube.

The Work of the Civil Surgeon in South Africa.—Two days ago I received a letter from the Station Hospital, Ladysmith, dated 1st November 1900, portions of which letter, with your permission, I will read, just to indicate the sort of work which falls to the civil surgeon in South Africa:—"I thought you would like to know more of the cases you were consulted about in the surgical ward here early in August. The Ayrshire footballer, with dislocation of the internal semi-lunar cartilage, I operated on; finding only a small portion of it turned over, I passed a chromic catgut through it and the capsule of the joint. The wound healed by first intention. The yeoman with acromegaly was discharged to Howick and invalided home. The orderly with varicose vein was operated on by tying the saphenous vein. He made an excellent recovery, and is regularly on duty. The young scout with locking of the elbow-joint was sent to Mooi River Hospital to have an x-ray photograph taken. The night he got there a great storm occurred. All the tents were blown down, and all patients transferred to various hospitals down the line. The most interesting case I think was the Grenadier Guard, in whom you diagnosed division from bullet wound of the median nerve. The day before I intended to operate I thoroughly overhauled the arm, trying to locate the ends of the divided nerve. In this I failed; but next morning he woke with returned sensation in the hand. I take it the nerve was not divided at all, but had become tied down, and strangled in fibrous tissue in the healing track of the bullet, and the manipulation had freed it. Under massage he made rapid progress, and was discharged to Howick with a very useful and still improving hand. I had my best week in South Africa last month. An operation for abscess of the liver from gall-stone; iridectomy for glaucoma; radical cure of hernia; laparotomy for an abscess of the spine after enteric, all doing well."

This letter is from Dr. J. B. RUDDUCK, civil surgeon. Possibly such a letter will best illustrate what seems to be an outstanding fact, namely, that the civil surgeons have been of much service in South Africa.

This paper is chiefly one of impressions. I wish I had been able to keep more notes, but the fact is that from the day I left Capetown until I reached Capetown again, with the exception of a few days at the Edinburgh hospital, I was constantly on the move and not placed in favourable circumstances for extensive note-taking. May I, in conclusion, express the earnest hope that the medical history of this war will be fully described in the form, and with the thoroughness, that the great Civil War in America has been dealt with by the Government of the United States. From such a history many most useful lessons will be learnt, which will be of the greatest use to all members of our profession, and especially to the Royal Army Medical Corps, and to those civil surgeons who may in the future be called on to reserve Her Majesty in times of war.

THE TREATMENT OF VARIOUS LONG-STANDING SEXUAL AND URINARY SYMPTOMS IN THE MALE.

BY FOLLEN CABOT, M.D.,

New York.

THE importance of determining the existing cause of various obscure sexual and urinary symptoms cannot be overestimated. Without this knowledge we frequently blunder and treat a patient for a condition which is entirely secondary in its nature. For example, a patient presents himself with a persistent urethral discharge. We find, upon examination, a congested, inflamed state of the anterior urethra; we thereupon proceed to treat this condition with various injections and applications to the front urethra. In some cases the temporary result is apparently good, the discharge and local symptoms subside and the patient is relieved. The local treatment is for the time discontinued, when the discharge and previous symptoms promptly return and leave us just where we were in the beginning. In other instances the condition is greatly aggravated by the above form of treatment, with the consequent loss of confidence on the part of the patient. In yet another class of cases complications result to remote parts of the genito-urinary tract. This is particularly so when strong, deep injections are used, or when sounds have been unadvisedly employed.

The complications in these cases may be caused by extension to healthy tissue from the part which is the existing cause of the trouble, or they may be due to a lighting up of a disease in an organ already affected. If the former is the case, we have done further damage to our patient and have made an already bad matter worse. If, on the other hand, the latter condition results, that is, a lighting up of the existing cause of the trouble, we certainly have given the patient no help.

In a small percentage of cases, direct or indirect extension of the disease to connecting parts follows with no apparent cause, but in the majority of such instances the aggravation and extension of the process is caused by the blind treatment of the physician.

It is evident that if we have a disease of the seminal vesicles, prostate, or COOPER'S glands, or of the deep urethra, where the anterior urethra is secondarily involved, treatment of the front urethra alone will not produce permanent relief. Occasionally, when the disease in these parts is mild, a cure will follow in spite of improper treatment; but such luck is not common.

If, by following general principles, we give deep injections of silver or sulphate of copper, or use sounds, etc., and only the deep urethra happens to be involved, relief occasionally follows. When, however, as is commonly the case, parts outside the urethra are diseased, we are likely to do damage, as already stated, by violently stimulating and injuring these delicate organs, already very sensitive, owing to their previously inflamed state.

Of course it is granted that the majority of the diseased processes in the male genito-urinary organs are caused by the gonococcus lodging in the urethra by way of the meatus, and later, in many instances, from one

A MIRROR OF PRACTICE.

A CASE OF MULTIPLE EXOSTOSES.

By ASSISTANT SURGEON Y. G. APTE, B.A., L.M.S.,
Memorial Hospital, Lashkar, Gwalior.

CHAND MAHOMED, a young Mahomedan of about 25 years, was admitted into the Memorial Hospital for a foul growth on his left thigh on 28th November 1900.

History.—The present complaint dates two years back. The patient had a congenital bony growth on the left thigh as elsewhere (described in detail below). While going about his work (he is an attendant in a club) he stumbled and was hurt on the growth. The part inflamed: swelling not disappearing with his own treatment, he was treated by a jarrha (a quack), who applied some (caustic?) applications, producing discharging openings all round the swelling. The trouble got much worse since the last four months, wherefore he sought admission into hospital.

Present condition.—On inspection, there is a large swelling about middle of left thigh, rising out quite at right angles to the length of the bone, almost in front. There is a very offensive smell. There are a number of discharging openings all round the tumour. In the centre is a black patch, which, on palpation, appears to be almost loose dead bone. The swelling has an inflamed angry look. There is some pain, increased on pressure; the tumour rises about 3 inches from surface of thigh, has a wider base than top, being 3 and 2 inches in diameter respectively. To the feel the swelling is hard and bony. The outgrowth appears to be continuous with the femur, although the very top (black patch) feels loose. On deep pressure the bone crackles, showing that there is some more dead bone within as the one piece visible outside.

Previous diseases.—The patient has a deformed osseous system (described below), and there are small bony outgrowths on various parts of the body. Some eight years back, while playing, he hurt himself on a small growth on the upper and outer part of the right arm. There was swelling, &c., which went to form an abscess: when it was opened, a small piece of bone was discharged with pus. It healed up well, leaving a cicatrix. Even now there is a small free bony nodule at the part.

There is nothing else significant in his previous personal history after birth, but there is an antenatal fact (?) to note that he was in his mother's womb for 13 months!

Osseous system.—There are bony growths on both the extremities, more on the lower, not symmetrical, of all sizes, from a small marble up to an orange, or, as on the left thigh, a large mango. They arise on all sides of bones, at all angles. The larger ones have usually a broad base, but in a few the attachments are much narrower than the bodies. They send out pointed and blunt processes in various directions, which are to be felt mostly subcutaneously, but also through muscles. They are most on the right leg, numbering there seven. They are on the shaft of the bones, except on the left wrist, where a few are situated on the lower extremities of the bones of the forearm.

The general stature of the man is a stunted one. But the upper limbs are particularly so, where the arm and forearm are much less in length than even proportionately to the lower limbs. Of the two, the left is shorter, the left forearm measuring only $7\frac{1}{2}$ inches long (the right being only one inch more). The left forearm is deformed in another direction, in that a forward and inward curvature of both bones in the lower half is very marked.

Besides the limbs, the rest of the osseous system is perfectly free on the surface, except for a small nodule on the left seventh rib near its anterior end. Even in the limbs, the hands and feet, the clavicles and scapulae, as well as the patellae, are free. There are no growths also in the inguinal, popliteal or axillary regions. There is no interference with the nervous or circulatory systems.

There is nothing else in his system to take note of. After these details, it is interesting to refer to his

Family History.—He has two brothers and a sister, who are perfectly normal. So are his parents and his mother's parents (nothing known on father's side). His uncle is free, but two of his (uncle's) five children—a boy and a girl—have similar growths, though not so numerous nor well-marked. To his knowledge these growths are also situated on the limbs, except in the male cousin, who has also one in the perineum, which gives him some trouble.

Diagnosis.—The bony nature of tumour is evident to feel. Deep pressure discovers that the bone, which was probably hard like the other tumours, has gone to pieces—the result of a traumatic inflammation. Their occurrence on the long bones, as well as their multiplicity, would suggest that they were cancellous exostoses. Their family tendency is brought out in the history. As described above, many of them are pedunculated, and irregularly lobulated on the surface, as cancellous tumours are.

Operative interference was necessary on account of the condition of parts in which the patient was admitted. The stink—the characteristic stink of bone pus—having been mostly removed by previous saturation with strong carbolic lotion, the patient was placed on the operation table and chloroformed. The intervening bridges of tissue between the several openings on the surface of the tumour were broken down with the fingers. The looseness of the bones became quite evident, as piece after piece was removed with the fingers and sequestrum forceps, and the chisel had to be used to remove the attached portion, which was more compact and hard than the upper, which was dead. While thus chiselling away, the tumour was discovered to have a somewhat narrow attachment a few inches above the lower end of the femur, and an upwards process going into the muscles beyond the breadth of the base of the tumour. On removing the pedicle the medullary canal was exposed, and drops of fat were seen floating in the blood accumulated in the wound. After all sharp points were taken away and smoothed, the wound was sponged dry, dusted with iodoform, and firmly bandaged. As the whole tumour was removed, and no skin covering it being worth keeping in its condition, there was a large deep wound exposed, but the filling up was rapid

and uneventful, and the patient walked out of the hospital on 18th January 1901.

Remarks.—The case is an instance of a deformity which is certainly out of the common. But for the accident and the consequent trouble in the growth, which did not in itself come in the way of his work, he would not have come to hospital. The exostotic growths have told upon the nutrition of the bones, which are shorter than normal and curved, especially so the left forearm.

But their influence in arresting the development of bones from which they spring is not noticeable in the left thigh (bearing the large tumour) which is quite as long as the right one. They do not also, in the present case, at all arise "at the line of junction of an epiphysis with the shaft," as they are said "almost invariably" to do (EBRICHSEN). It may also be noted that they are congenital and have a family tendency which is somewhat curious, inasmuch as they occur in cousins, but not in brothers or parents.

AN OPERATION DEvised FOR THE TREATMENT OF MARKED PROLAPSE OF THE RECTUM IN WOMEN.*

By J. WESLEY BOYER, M. D.,
Washington, D. C.

THE treatment of exaggerated rectal prolapse has taxed the most skilful surgeons of the world. Various methods in the way of plastic operations and the application of the cautery and many ingenious devices have been resorted to, but generally these have been inadequate and unsatisfactory, even when repeated a number of times on the same patient. Generally, resection of the rectum from below has been the best plastic procedure, but this has failed even when repeated. This procedure is much like shortening a drainage-tube by frequent amputations. In 1889 JAENNEL (*Gazette hebdomadaire de médecine et de chirurgie*, xxvii, 1890, p. 246) proceeded by a different method, one original with himself, I believe, and one which bids fair to meet with favor in the surgical world.

Instead of pulling down and cutting off the end of a loose rectum, as had been done previously, he elevated and fixed the colon to an artificial anus wound in the iliac region. BRYANT, of New York (*Annals of Surgery*, xxvi, 1897, p. 165), found records of twenty-nine cases, including his own, of operation by this method. In some of them the technique was slightly modified. These cases were all primarily successful. Omitting three cases in which dates are not given, we have twenty-six reported from two weeks to two years after the operation, in which there was but one return (reported more than a year after the operation), with one partial return.

It has been urgently recommended to make an artificial anus at the same sitting, that suspension of the physiological function of the rectum might be attained. This was due to the belief that the usual attending rectal disease was greatly improved by such rest. This idea is no doubt correct. Indeed, BRYANT noticed a proportionate return of the prolapse as the unnatural anus became

smaller. This relapse should not occur, though this tendency may be considerable, if the bowel attachment is made to fascia instead of to peritoneum, as has been the rule in these operations. Again, if the area of the bowel adhesion is increased, such return would be less likely to occur. A considerable number of these attachments have been made to the epiploica and a few to the mesentery, certainly not structures exerting much resistance. The difficulty of closing these artificial an is great, in even the small ones, requiring repeated operations. And in those sufficiently large to completely perform the function of the rectum, it is still more difficult. This feature would seem, therefore, to be one to be avoided if possible. It produces a very troublesome condition, loathsome to the patient, and presages one or more operations. Then, too, the danger of ventral hernia at the site of the colotomy is great, often necessitating a severe subsequent operation.

In my case marked prolapse of the uterus was associated with hemorrhoids and great procidentia of the rectum in a woman to whom the uterine appendages were of little value. No simple operation would have relieved the rectal condition while the uterus was in such a state of prolapse, and *vice versa*. These conditions thus associated caused me to resort to the unique radical procedure to be later described. While not applicable to all cases, as firm attachment of the uterus to the abdominal wall is necessary, a condition not consistent with safe child-bearing, it has a limited field in rectal prolapse in women. It is not improbable that marked rectal prolapse, associated as it is with proctitis and tenesmus, is usually productive of some degree of uterine prolapse. This being true, this operation, so far as I am aware, the first of the kind, will have a sphere, though necessarily limited, in the treatment of these conditions. Removal of the appendages is not necessarily a feature of this operation, yet sterility should be certain, or nearly so, as an indication or justification. Though the patient is perfectly well, with no evidence of relapse at the end of eight months, it is yet too early to record a perfect result. The prospect, however, is the brightest. The history of the case is as follows:—

Sister V—, a Sister of Charity in a neighbouring city, was thirty-five years of age. She had been treated unsuccessfully a number of years for prolapse of the rectum and uterus, and hemorrhoids. When she came under my care, she was suffering from large internal and external hemorrhoids and a protruding roll of fully three inches of the rectum, that was thickened and much discolored. The uterus was of about normal size, with its cervix just behind the pubes and the fundus very low posteriorly. A few days later, on March 6, 1900, the operation was done. The hemorrhoids were first removed, then the abdomen was opened by the usual subumbilical median-line incision. The left ovary was of about three times its natural size, and largely consisted of numerous cysts. The appendages were removed and the uterus was firmly fixed to the abdominal wall by four strong interrupted catgut sutures, which passed through a considerable portion of the uterine fundus at the top and the principal fascia of the abdominal wall on either side of the incision. The rectum was now drawn upward until it was fairly tense, and was so held by an assistant until it was sutured to the *cul-de-sac* and posterior wall of the uterus up to the abdominal wall. This was done by a running catgut suture. It completely divided the retro-uterine pelvic cavity into two equilateral ones.

* Read at the Thirteenth Annual Meeting of the Southern Surgical and Gynecological Association, held in Atlanta, Ga., and sent to the *Record* for publication.

VESICAL CALCULUS: LITHOLAPAXY: SUPRAPUBIC OPERATION.

By T. M. SHAH L.M.,

Medical Officer, Junagadh State Hospital.

JERAM RAMA, male, aged 40 years, admitted on 15th October 1900 with symptoms of vesical stone, said to be of fifteen years standing. Bladder was sounded and stone detected; urine was acid; specific gravity 1010 with mucous and albumen about half in quantity.

18th.—Patient was placed under chloroform. Morphia ($\frac{1}{2}$ grain) injected hypodermically. Lithotrite Nos. 12 and 16 passed, but stone being large it did not come within grasp; meatus then was incised and lithotrite No. 20 passed; calculus was partly chipped. It was extremely hard, and both personal as well as assistants' efforts in screwing up the instrument and crushing the stone failed. Some debris was aspirated twice.

After half an hour's futile efforts, suprapubic operation was performed. Bladder was filled with water. Sound was passed in; usual incision in the lower part of abdomen was made; all the tissues were divided. There was free oozing of blood from the veins. The bladder wall was transfixed with silk thread and then it was opened by knife guided by the tilting up of the point of sound. Fluid escaped; forceps introduced. As the stone was large, the bladder incision was enlarged, and then the stone was twisted out.

Stone weighed 1150 gra.; debris weighed 245 gra.—total weight 1395 gra.

Bladder was then washed out.

Two catgut sutures were passed in order to contract the bladder wound. Two wire sutures were passed and the abdominal muscles brought together. Four silk sutures closed the abdominal incision, and intermediate horse-hair sutures were applied. The lowest part of the wound was not closed in order to allow passage to urine that may dribble.

Iodoform was sprinkled and lint and bandage completed the dressing. Rubber catheter was passed into bladder per urethra and retained, so as to let urine flow out.

19th.—Catheter was out during night and dressing was soaked with urine. Catheter was reintroduced.

30th.—Urine passes mostly by the wound, some portion per urethra. Patient gets some rise of temperature in the evening; it is normal in the morning.

10th November.—Abdominal wound has assumed sloughy appearance; sutures have given way; the abdominal wound is gaping; all urine passes per abdominal opening. The parts emit offensive odour. The cellular tissue in front of the bladder has also sloughed.

20th November.—All slough separated; the wound is nicely granulating and contracting. Half the urine passes per urethra.

5th December.—Abdominal wound closed and all urine passes per urethra. Patient is gaining flesh and is now quite comfortable.

7th.—Discharged well.

Remarks.—Litholapaxy is now the ruling operation for vesical calculus. Other operations for stone are resorted to under exceptional circumstances, such as the case under report, the stone being too hard to be crushed by lithotrite. Besides this, when stone is too large, when it is encysted, and when urethra does not admit in adequate lithotrite, litholapaxy is out of question.

Litholapaxy is otherwise applicable to all ordinary stone in either sex and at all ages.

When a stone is large and hard, it becomes a troublesome operation to the surgeon, though very safe for the patient.

In the case of hard stones I utilize, besides personal efforts, the help of assistants or the leverage of a

forceps in screwing up the blades. In many cases screw up the main blade tight and wait for a while till the cracking of stone is heard.

Besides thorough crushing, complete aspiration of debris is very desirable.

In children it is a source of more or less bother when the stone is comparatively big and the quantity of debris is large. The canula admissible is necessarily small, Nos. 6 to 8, and its calibre is so often blocked up by the debris. Any remnant of debris acts a good deal of irritation in the bladder of the patient and causes anxiety to the surgeon.

In adults with ordinary stones, litholapaxy is a charming and excellent operation.

LAPAROTOMY FOR INTESTINAL OBSTRUCTION REPEATED WITHIN SEVEN MONTHS.

By LIEUT.-COLONEL J. LEWTAS, M.D., LOND., I. M. S.

ON April 21st, 1899, I received a telegram from Dr. HUMPHRY, of Kurseong, near Darjeeling, asking me to go there prepared to operate on a case of intestinal obstruction. On arrival I found the patient, a young lady of 28, with all the symptoms of an advanced stage of obstruction, such as collapse, intense pain in the abdomen which was distended, and constant retching. Assisted by Dr. HUMPHRY and Dr. SEAL, I opened the abdomen by the usual median incision, and found about 6 inches of the small intestine contracted to about the diameter of a lead pencil, the part above being greatly distended. No constricting band could be found. After pressing the contents of the upper part of the bowel through the constricted portion, the incision was closed in three layers, and she made a good recovery. But about three months later she began to complain of abdominal pain, which felt, she said, as though "something was drawing the cicatrix backwards to the spine." I heard no more of her until November 5th, when Dr. HUMPHRY telegraphed again under the same conditions as before, but as I could not go to Kurseong, he brought the patient to me, and on November 6th I again opened the abdomen through the former cicatrix. I hoped the operation might have thrown some light on those abdominal pains of obscure origin which are not uncommon in the after-years of patients who have undergone abdominal section; but it did not do so; no bands or adhesions were found, and the condition of things was a precise reproduction of that found at the previous operation—namely, extreme contraction or collapse of a few inches of the small intestine. Again she made a quick recovery, and there has been no return of abdominal pain since the second operation. Of the anatomical cause of the obstruction nothing definite can be stated further than to say it was not due to either a band or an opening in the mesentery, nor did the constricted part of the intestine appear to lie in a retroperitoneal pouch: hence one is almost driven to conclude that obstruction may be caused by spasmodic contraction of the gut itself. The history of the first attack is suggestive, as it came on after an effort to carry upstairs a housekeeper who had snuffed not wisely, but too well.

Indian Medical Record.

ORAL SEPSIS AS A CAUSE OF "SEPTIC GASTRITIS," "TOXIC NEURITIS," AND OTHER SEPTIC CONDITIONS.

IN a communication to a contemporary, Dr. WILLIAM HUNTER, M.D., F.R.C.P., deals most convincingly with the somewhat novel and neglected, though none the less important, question of Oral Sepsis as a Cause of "Septic Gastritis," "Toxic Neuritis" and other Septic Conditions. His remarks and opinions are lucidly illustrated with appropriate cases, and we consider the paper well worthy the perusal and consideration of the entire medical community. We essay a review. After stating how common a cause of disease oral sepsis is, how grave its effects, how constantly overlooked and what remarkably beneficial results could be got from its removal, the author proceeds to discuss the local effects of oral sepsis, showing that, in the mouth, it produces dental necroses in all cases, gingivitis and stomatitis of every degree of intensity, periostitis, pyorrhoea, alveolaris and deposition of tartar; in the jaws, it produces alveolar abscesses, osteitis, osteomyelitis, necroses and maxillary abscess, and in parts adjacent to the mouth such affections as tonsillitis, pharyngitis, otitis, glandular enlargements, cellulitis, post pharyngeal abscess, ethmoidal suppuration, and even meningitis by direct extension. That these effects were not even more common was due to the remarkably resistant powers of the mucosa of the mouth, for sepsis connected with diseased teeth was of a particularly virulent character, much more so than the pus derived from soft tissues. It was well to remember that pyogenic organisms were always absent in teeth successfully dealt with antiseptically. A mere question of the presence of an organism was not, however, the only factor. *Dose and resistance* were important, the former especially when a whole series of teeth were affected—dark, necrotic, lying in inflamed, septic and possibly suppurating sockets. The effects of such a condition were not limited to the local sepsis. They were more widespread and were of three kinds:—

(A) *Gastric and Intestinal Effects.*—Gastric catarrh with nausea, distaste for food, sickness, gastric pain, &c., associated with poor nutrition, depression, weakness and a dirty sallow complexion. If there was a continual source of infective generation going on around the teeth, it was not difficult to understand infection occurring lower down in the gastric mucosa itself. It was this condition which the author proposed to designate "Septic Gastritis," the title septic accurately describing the cause and the nature of the resulting catarrh. It was pointed out that the relation between dental disease and indigestion was in most minds considered a "mechanical" one, with others bad teeth denoted bad nutrition and bad health—they were the result of ill-health rather than the cause of it—but there

was a third relationship far more important than these, namely, that dental disease was a cause of indigestion in consequence of being a continual source of septic poisoning and septic gastric infection. The author sums up this relationship thus:—(1) There is a limit to the capacity, even of the stomach, to resist indefinitely for periods of years the continuous presence of pyogenic and other organisms derived from cario-necrotic conditions of the teeth. (2) Its powers of destroying such organisms, although great, are never complete even in health, and are due solely to the presence of free hydrochloric acid. (3) These powers become progressively weakened when, through any cause, an increased and continuous supply of pus organisms is associated with a diminished and continuously lessening acidity of the gastric juice. (4) These two conditions are precisely those produced by cario-necrosis of the teeth. (5) In time the catarrh of the stomach, so common a sequel of imperfect dentition—possibly of a simple irritant nature to begin with, the result of fermentation—becomes septic in its character, that is, really a septic gastric catarrh. (6) Eventually it may even lead to the deeper seated changes which always result from chronic catarrh, viz., atrophy of secreting structures, with increase of fibrous tissue (chronic gastritis with atrophy of the glands).

Cases of gastric catarrh in association with dental and oral sepsis were met with daily. The ashy grey look and general languor in such cases were manifestations of long-continued septic absorption: the local symptoms of clamminess in the mouth, distaste for food and coated tongue were really the result of the oral sepsis, while the nausea, indigestion and gastric discomfort were the result of "septic" gastric catarrh produced by direct infection of the stomach with pus organisms. Here the writer illustrates his remarks with six cases showing the frequency of these conditions and the extraordinary way in which the most remarkable conditions of oral sepsis were overlooked while the patient was being all the time sedulously treated for the local effects. In one case Dr. HUNTER was able to demonstrate conclusively not only the septic nature of the gastric catarrh—the catarrhal exudation vomited being loaded with pus organisms,—but also its persistence, since the condition continued three weeks after removal of all source of oral sepsis. How much more, then, was this condition likely to exist when the oral sepsis is extreme, as it often was, and the patient had to swallow pus organisms continuously for many years!

(B) *Remote Infections.*—Including the whole series of infections caused by pyogenic organisms, such as acute osteo-myelitis, ulcerative endocarditis, empyema, suppurative meningitis, suppurative nephritis, etc., with other obscure septic conditions characterized by fever, purpura, bleeding from gums, etc. The author did not consider this aspect of the subject.

(C) *Toxic Effects.*—Including symptoms due to septic absorption, apart from any actual general infection. They were extremely common, and, like all the other effects of oral sepsis, no less commonly overlooked.

There were the usual signs, but often *without any local symptoms*, for these effects were by no means necessarily proportionate to the violence of the local symptoms. The following effects were among those the writer had met with: (a) Fever—of obscure character—really septic; (b) septic rashes; (c) purpuric hæmorrhages and bleeding from the gums like signs preceding ulcerative endocarditis; (d) profound septicæmia; and (e) nervous effects, alluded to now for the first time by Dr. HUNTER, under the title Toxic Neuritis. The absence of local effects was often due to the very intensity of the poisoning. The tissues were able to offer no resistance at all. If the local effects had been as marked at the outset as they were at the termination, the general toxic effects would not have been so marked. They included the ordinary effects of blood-poisoning, namely, lymphangitis and high fever. One case cited in this connection is especially interesting, confirming, as it does, the writer's conclusions regarding the infective (partly septic) nature of pernicious anæmia, and the importance of oral sepsis in relation to it. The author then describes twelve cases indicating that, apart from any connection with pernicious anæmia, toxic neuritis with numbness, tingling in hands and feet, loss of knee-jerk, marked wasting of certain muscles and local palsies, was met with in connection with extreme conditions of oral sepsis. In all the cases the nervous effects were very marked: in all the most intense condition of oral sepsis prevailed, lasting for many years, and in all cases immediate improvement resulted from removal of this condition. In dealing with the phase of this subject as to oversight in regard to the importance of oral sepsis, the writer indicated that not only in general treatises of medicine, but in special treatises dealing with the individual diseases, such subjects as *stomatitis*, *tonsillitis*, and *pharyngitis* were discussed without the slightest reference to sepsis within the mouth as a possible source of infection, and, as regards the teeth in particular, without other reference than to the possible effects of "persistent irritation by a broken or sharp tooth." Gingivitis and stomatitis were the commonest effects of sepsis in connection with diseased teeth: the cases in which it was most intense and widespread were those in which tooth-plates were worn covering diseased roots, particularly if not regularly removed. These affections were regarded in general as the effects of general conditions rather than as effects of local causes. For catarrhal and follicular stomatitis, every possible cause had been ascribed with the single exception of local septic trouble in the mouth, and the same could be said of ulcerative stomatitis. By only one of the most recent writers (Dr. WILLS: "Allbutt's System of Medicine") was the condition of the teeth recognised as a very important element in the production of the ulcerative form of stomatitis, inasmuch as it never appeared before the teeth. Examination of the teeth was always inculcated as important: since notching of the teeth might denote syphilis, a blue line on the gums lead poisoning, and looseness of the gums, scorbutic conditions; but nowhere was there any reference to the extraordinarily septic conditions seen in the mouth in everyday practice as the result of septic inflammation arising from necrotic teeth. The same remarks held

good in tonsillitis and pharyngitis. These were got rid of by removal of the causes of the sepsis—necrotic teeth and septic stomatitis. As regards pharyngitis, dyspepsia and constipation had been described recently (Allbutt's System of Medicine) as the most potent causes, and the class of case thus arising had been regarded as toxic in origin, due to failure on the part of the liver to destroy toxins resulting from imperfect digestion, or from decomposition in the intestine, these toxins like belladonna exerting a specific action on the pharyngeal mucous membrane. In the author's opinion the relation between the pharyngitis and these various disturbances was of another kind. They were all the results of septic gastritis. The pharyngitis was not caused by them: but both alike were part results of the primary septic condition within the mouth. In the case of septic gastritis the oral sepsis was most constantly overlooked while the patient was sedulously treated for its effects. The patients in all these affections would have suffered much, heard much, and been possibly medically and dentally treated: but as regards the teeth, the only one fact learnt was that, if the teeth were not in order, indigestion must be expected, as proper mastication was interfered with. The profound sepsis induced as aforesaid was never dreamt of.

Treatment.—It was to be remembered that what was being dealt with was pus-forming organisms which were constantly present in the mouth in connection with necrotic teeth. What was wanted was a fuller recognition on the part of all—physicians, surgeons, dental surgeons and patients—of the septic nature of this condition of caries of the teeth. The gastric troubles were not the result of any dyspeptic trouble or of ill-health or of insufficient mastication: they were the result of sepsis caused by carious teeth. The chief problem was to find out where the pus organisms had gained entrance. In regard to oral sepsis, the author thought that there was a wide field open for preventive medicine by the practice of oral antiseptics. In this expression oral antiseptics, Dr. HUNTER did not mean any general application of mild astringents or antiseptic washes. He meant: (1) The direct treatment of each lesion in connection with a diseased tooth by strong antiseptic solutions: carbolic acid 1 in 20 or 1 in 40 periodically applied as long as the patient delayed having the tooth removed, or as long as there was the slightest redness around the root. A teaspoonful of 1 in 20 carbolic acid in half a tumbler of water formed an agreeable mouth-wash. (2) Removal of all diseased stumps and roots, in particular those lying underneath any tooth plate. (3) The dentist must not only supply his patient with tooth-plates: the patient will have to be educated and shown that these plates were the cause of septic trouble unless they were daily sterilized. (4) There should be an entire avoidance of any dental apparatus (liable to become septic) which could not be removed, and therefore which could not be kept aseptic.

SUPRAPUBIC CYSTOTOMY FOR REMOVAL OF GROWTHS IN THE BLADDER.

THE *Practitioner* publishes in detail a clinical lecture on Suprapubic Cystotomy, delivered at St. Bartholomew's Hospital by Mr. ALFRED WILLETT, F.R.C.S., Surgeon to that Institution. We call the essentials. The object of the lecture is apparently to advocate the extension of this method of operating in reaching and exploring the cavity of the bladder, and for dealing with cases of suspected new growths located in it, especially as in the latter cases, though the legitimacy of the operation was unquestioned, it was still somewhat on trial, and its expediency was called in question by many. One extremely prominent advantage of the operation in doubtful cases was the arrest or cessation of hæmorrhage when present. The lecturer then detailed three cases of much interest in which suprapubic cystotomy had been performed: the first, in a woman for the removal of a papillomatous growth which, after much trouble, had been diagnosed by rapid dilatation of the urethra and examination with the finger under an anæsthetic; the second, for the removal of a stone which had failed to be crushed by the lithotrite—on *post-mortem* the real disease was found to be a new growth, a noteworthy fact, considering the opportunities for discovering it; and thirdly, in a patient in whom nothing beyond enlarged prostate could be diagnosed, but in whom other symptoms indicated something wrong with the bladder—two small filiform papillary growths above on the left side were found and removed by the finger, and the patient convalesced without a symptom. There was an essential difference in reference to diagnosis between the first, and the second and third cases; that is, between bladder diseases occurring in women and those occurring in men. In the former, a suspicion of growth in the bladder could be set at rest by dilatation of the urethra and digital exploration of the interior; but in the case of men the difficulties were very great. If one, however, could exclude stricture, prostatic disease, stone cystitis (simple or tubercular), gross kidney disease, and if no tumour could be felt, there remained only new growths, and the bladder was the most common situation for these. The lecturer regarded hæmorrhage as by far the most important, for if it was of the bladder type and intermittent, coming on unceasingly, even when the patient was lying quietly in bed, and occasionally was profuse, there was always a strong indication of a new growth in the bladder. In regard to the cystoscope as an aid to diagnosis, Mr. WILLETT could not say that he had acquired confidence in it after much familiarity. Sometimes the illumination was defective; sometimes the media could not be kept clear; but the main obstacle seemed to be defect in, or uncertainty of, being able to bring into focus the whole interior of the bladder. He always used it in doubtful cases, but was not by any means convinced there was no growth if none was discovered. Sounding independently of the cystoscope should always be done, for one might detect a large growth by it almost as certainly as a stone. The sound might refuse to travel along one surface or one side, or it might be suddenly caught, or it might jump over an elevation. On the other hand, sounding might excite sharp hæmorrhage. Digital examination *per rectum* should always be made: the trigone area was one where

growths were very frequently found: a tumour or more probably an indurated or thickened condition might be felt whilst the finger was in the rectum, the other hand palpating the hypogastrium. Even with the microscope there was much disappointment, for rarely was any living tissue voided, but only *débris* of a quite structureless form. It was unlikely that the Röntgen rays would be able to aid in diagnosis, owing to the extensive bony environment. Diagnosis could rarely be quite certain. The lecturer then considered under what circumstances a surgeon would be justified in recommending a male patient to submit to operation. These were: (1) In all cases where hæmorrhage was alarmingly great, threatening life if allowed to continue. (2) In cases where ordinary ailments which lead to severe bladder disease can be excluded, where the routine treatment of bladder symptoms has failed, and where the patient's life is rendered miserable and the disease advancing towards a fatal termination. (3) In cases where the bladder hæmorrhage was unaccountable on any other hypothesis than a growth. In all these cases, however, the growth was merely probable. Opinion might have to be given where, either by the cystoscope or digital examination or sounding, there was a greater certainty as to the existence of growth. In all such cases should the bladder be opened? Mr. WILLETT was inclined to say, "generally Yes;" and unless there were contraindicating conditions, such as that the patient was in too bad a general condition to recover from any serious operation, or when the local condition was obviously too extensive for any hope of successful removal, or when it was probable that secondary deposits existed in other organs. In other words, the operation should be performed when, after the fullest investigation, the surgeon is in doubt, and the patient, thus given the benefit of the chance it afforded of obtaining cure or relief. Generally the case presented itself thus: A man is incapacitated: he is also in considerable pain by day and by night: he is subject to attacks of hæmorrhage, more or less severe, and of more or less frequent occurrence. If all temporizing or expectant treatment had failed, and the patient refused operation, that man must be regarded as incurable. On the other hand, if he submitted to operation, there was the chance of a readily removable growth being found. Unquestionably, then, it was even well to meet with disappointment in some, if only in a few complete recovery resulted. And even in the failures no harm ordinarily resulted by the mere opening and either immediately reclosing the wound or adjusting a shield and drainage of the bladder. In some cases severe hæmorrhage had been arrested in malignant growth by the mere act of opening the bladder. The operation itself was so well known that the lecturer did not think it needed description.

COMMENTS AND NEWS.

A PLEA FOR A MORE RATIONAL PROGNOSIS IN CARDIAC AFFECTIONS.

J. J. MORRISSEY, A. M., M. D., Visiting Physician, St. Joseph's Hospital; Chief of Clinic Out-door Department, St. Vincent's, New York City, says:—

1. When a heart murmur is discovered, do not give a gloomy prognosis on that simple fact alone; consider the condition of the cardiac walls, the probable length of time the lesion has existed, the presence of dilatation or hypertrophy, or both combined. The occupation and temperament of the patient are very essential factors in the prognosis. Each individual is a law unto himself, and though certain general principles may be established as a basis on which to build a working prognosis, remember we have no real means of recognising the strength of the individual heart, except its power of resistance against the poisonous effects of alcohol and tobacco, or the inroads of the acute or chronic diseases, or the stress of laborious occupations, or the debilitating influence of prolonged exposure. The diagnosis should be complete, the prognosis tentative. Or, as a distinguished English colleague has said: "Give your prognosis on the best suppositions, treat your patient on the worst." (ALLBUTT.)

2. Remember that murmurs do not invariably mean endocarditis, and a prognosis based simply on the presence of a murmur would be rank injustice to the patient, and demonstrate incapacity on the part of the physician. As a skilled observer has well stated: "With an apex-beat in the normal situation, and regular in rhythm, the auscultatory phenomena may be practically disregarded."

3. To those of us who are interested in life-insurance work, this is of great importance. We wish to be just to the applicant, and at the same time do our duty toward the company. The fact that a man has a murmur at the apex, of which he is entirely unconscious, whose heart is doing its work thoroughly, despite the existence of the lesion, whose occupation is not of an adversely laborious character, who has passed that period of life when acute rheumatic infection is liable to stimulate into fresh and renewed activity the latent inflammatory products of an ancient endocarditis, should be factors to guide our judgment as to the probabilities of the future and prompt us in recommending for him a policy commensurate with the degree of cardiac inefficiency.

It should not be forgotten in this connection that a presystolic murmur does not always indicate the most serious of all lesions, viz., a mitral stenosis, nor has a so-called musical apex-murmur any particular significance in prognosis, indicating, as it does, the passage of a stream of blood through a small aperture in the segment of a valve.

4. From the standpoint of longevity, aortic stenosis is a favourable lesion, and the writer must differ from some authors who state that it appears for the most part after middle life. It is found at that period when a man should be at the highest point of physical capability, between 30 and 50. It is true that it is frequently present as part of a general decay, and then develops in consequence of atheromatous changes taking place throughout the system; but it is more frequently present than has hitherto been suspected without such pathological manifestations being present.

5. Do not inform a young man between 18 and 25 that he has heart disease, because you discover some hypertrophy without complications, the result in most instances of active exercise. The writer knows of one individual whose heart is "athletic," a splendid specimen of manhood, whose existence was embittered by the thought of heart disease communicated by a careless and injudicious physician. In this condition it is of course understood that a careful consideration will be given to a large number of causes, independently of hypertrophy; for example, that typical enlargement of the heart co-existing with an interstitial nephritis.

Never hesitate to ask a patient to return for further examination, as the condition then may be entirely different from the first examination. There are more snap "diagnosis" made in the realm of cardiac affections than in the study of diseases in any other portion of the body.

MIDWIVES FOR POOR WOMEN IN BOMBAY.

THE *Indian Municipal Journal* says:—It has been said that the Corporation of Bombay is infested with doctors, but even if it be so, there are times when they prove themselves to be really "handy men." They did excellent work in a committee which recently reported to the Municipal Commissioner on a proposal to provide a staff of qualified midwives in Bombay to take the place of the "ignorant, untrained, and not over-clean women who usually attend at childbirth in poor families."

While agreeing unanimously on the need of this change and on the good that would result from it, there were three dissentients who wished to modify the proposals of the majority. The proposals were briefly as follow:—To engage eight diplomaed midwives and locate two in each of the four divisions of the city. Each midwife should live in the ward in which she is to work, and should be available for rendering assistance free of charge to poor women under rules to be made by the Corporation. The proposed pay of these midwives is Rs. 75 a month with Rs. 25 as a supplement for gharry hire and contingencies.

Dr. Sir BALCHANDRA KRISHNA was of opinion that one midwife in each division would suffice to begin with, and that Rs. 50 would be a sufficient monthly pay. Mr. DHAKJEE CASHINATHJEE was of the same opinion, but Dr. ISMAIL JAN MAHOMED, taking a very practical view of the subject, saw that in view of the possibility of more than two cases occurring in any ward simultaneously and requiring the aid of the midwives, the project might suffer; he therefore suggested that there should be at least half a dozen competent midwives in each ward, and that their pay should be at least Rs. 100 per month. This would cost from sixty to seventy thousand rupees per annum. But, said he, even with this the remedy will not be complete, for besides the mischief caused by ignorant "dhis" and the deep-rooted prejudice, there is the insanitary condition of the houses and rooms where the confinement takes place, and every private practitioner in the city knows in how small, insanitary, and densely-populated houses and rooms confinement cases occur, and how they become victims of fever. "Personally," said the doctor, "I think that unless we provide improved sanitary buildings for confinement for the poor, and give them the assistance of qualified midwives, no benefit will result. In my opinion the Lady Dufferin fund is the proper channel through which the attempt to render help should be made, instead of the Municipality undertaking to do so itself."

The public is indebted to this committee for their report it exposes a state of things which we hope may soon find

a remedy, but taking all the opinions together, it becomes a question of reforming the "dhals" and overcoming some very deeply rooted customs and prejudices. The examples of the Parsees Lying-in Hospital must not be relied on too much, for of all the peoples of India the Parsees have shown the greatest power of adaptability in the line of progress. The much desired change in the treatment of childbirth can only come on slowly, and as a beginning must be made, it can only be with the aid of a few very carefully selected women, whose tact and commonsense will save them from the opposition which too much enthusiasm often provokes.

A "dhal" working among the lower classes will not earn more than forty rupees per month; she does not enjoy much consideration among her clients, but her duties offer occasions for arbitrary and at times reckless acts. If she is fairly well occupied, education would not be likely to increase her revenue, for the client would not pay more, although the service might be worth double the price. How then is better knowledge to be introduced to the "dhal"? It is plain that she must have a practical education, and as a proof of it she must possess a certificate. It is most unlikely that she will pay for her education—so unlikely that the scheme of her education should include her keep. And as it is quite possible that free keep, education, and certificate may not be sufficient inducement to women who can and do make their living without them, a small sum monthly might accompany the certificate for, say, a year after the certificate is granted. The amount of instruction they should receive is a matter of great importance. It is so easy to overdo it by making the standard too high at first, and repelling the class that should be benefited. We would suggest that the course of instruction should be the simplest that could be safely imparted at first, and as time went on it might be extended on the experience gained.

The improvement of the "dhal" is simply a new phase in the great problem of Technical Education—that branch of knowledge which depends so much on the training of hand and eye, and so little on book knowledge. In the present case it must be based on a non-literate standard, in order to meet the conditions of the class it is intended to instruct. Should literary qualifications be insisted on, a quarter of a century will not bring the scheme in touch with the actual requirements of the people, and the average pay remaining the same, the "dhal" will continue to be recruited from the same class as before. The art of imparting knowledge of the right kind, and to the right amount, for educational purposes, is still in a state of very imperfect development.

MASSAGE OF THE EYEBALL.

THE *Journal of the American Medical Association* publishes a paper on Massage of the Eyeball, presented to the Section on Ophthalmology at the fifty-first annual meeting of the American Medical Association, by Dr. CASSEY A. WOOD, M.D., of Chicago. We summarise. The writer speaks particularly of simple, and not instrumental massage. OOSTOMIRIS, of Athens, believed that direct massage of the finger tip on the exposed cornea or conjunctiva gave the best results; but Dr. CASSEY WOOD considered the movements over the lids with slight pressure sufficiently efficacious and certainly less difficult and better borne. The act should never of itself produce pain, and rarely more than a passing discomfort; little was to be gained by the employment of much force. The patient should look down when massaging the upper lid, and up with the lower lid: if the cornea was to receive attention, the patient should look straight forward. It was better to perform a gentle non-irritating massage of even ten minutes' duration daily than a rough, painful

rubbing twice a week. As regards remedial adjuncts for simple massage, the writer used a drop or two of cod-liver or castor-oil, and for the rest preferred oily solutions or mixtures to powders or collyria. When these oleaginous compounds were made perfectly smooth and of a consistency that permitted their ready distribution over the eyeball, it was surprising how little pain or discomfort was set up even by strong doses of such irritants as mercuric chloride, silver nitrate, etc. This was probably due to the fact that massage had an anæsthetic action, probably due to emptying the capillaries and lymph vessels of their contents, and to the continued pressure on the nerve endings. The most useful massage agents were mercurials combined with all sorts of oleaginous excipients. At the end of or during the act, combinations of the remedy with the ocular secretions—especially mucous—should be coaxed out of the sac by small "dabs" of damp cotton or the irrigating stream, and the stroking movements resumed until nothing further comes away. The patient, half an hour after the lid friction, should not experience any added discomfort. In a general way massage would be found most useful in chronic diseases of the eye borders and substance, in almost all subacute and chronic affections included in the term "conjunctivitis," in the second state of acute inflammation of the conjunctiva, in most forms of ulcer of, and deposit in, cornea, and for the temporary relief of glaucoma, and in some forms of retinal embolism. It was contraindicated in "acute conjunctivitis," "keratitis," true trachoma, and in diseases of the iris ciliary body, lens, choroid, vitreous or optic nerve. In young subjects it lessened the opacity following ulcer of the cornea, and was also for the same reason valuable in the treatment of interstitial keratitis.

STERILISED CHARCOAL AS A-SUBSTITUTE FOR IODOFORM IN THE TREATMENT OF SURGICAL TUBERCULOSIS.

FOR the last six months Dr. A. FRANKEL, of Vienna, has substituted sterilised charcoal for iodoform in the treatment of local tuberculosis.

After the wound of the tuberculous tissue, he fills the operation wound with glycerine containing in suspension 10% of powdered animal charcoal, prepared exclusively from bones, and sterilised for 10 to 12 hours in an oven at a temperature of 150 to 160° C.: he then sutures the incision as hermetically as possible, and applies an aseptic dressing, which he leaves in position for two or three weeks.

When the complete closure of the wound by sutures is impossible, he introduces into the wound pieces of white calico saturated in a mixture of glycerin, alcohol and sterile powdered charcoal. At the end of eight days he removes the dressing and proceeds to extract the plugs.

The first thing that strikes one in cases treated in this manner; the absence of those considerable rises of temperature which usually occur and persist for several days after the injection of iodoform and glycerine. In a few cases only has Dr. FRANKEL observed a transitory fever, not above 100.4° F.

As for the effect of the charcoal upon the tissues operated on, it has been quite as favourable as that of iodoform; like the latter drug, the charcoal dries up the secretions, favours cellular proliferation, and leads to rapid cicatrization, which so far has never been followed by any local relapse.

In the experience of Dr. FRANKEL, powdered charcoal has only proved itself inferior to iodoform as a deodorant. Accordingly, in operations for the radical cure of chronic

otorrhoea or of maxillary necrosis with fisted discharge, it is preferable to use iodoform. But with these exceptions, where it is necessary to stimulate the development of fleshy granulations, or the cicatrization of recent wounds, to dry up secretions, powdered charcoal should be preferred to iodoform.

There is one drawback which, however, can be avoided, namely, the tendency to the formation of black pigment at the site of cicatrix, due to the penetration of grains of charcoal into the depths of the skin.

MEMORIAL OF THE STUDENTS OF THE LAHORE MEDICAL COLLEGE.

THE following memorial has been submitted by the students of the Lahore Medical College to the Lieutenant-Governor of the North-Western Provinces:—

"We, the undersigned memorialists, who are students in the Lahore Medical College, from provinces other than the Punjab, and mostly belonging to the University of Allahabad, hail with great joy the news of raising the Agra Medical School to the status of a College with a view to perpetuate the memory of our beloved Sovereign, the late Queen-Emress.

Nothing can be more gratifying to Your Honour's memorialists than that such a beneficial institution, extending its help and utility to all classes of the people of the N.W. Provinces and Oudh, should be established as a memorial to Her Majesty the late Queen-Emress, inasmuch as this is the most fitting tribute that can be offered on such a sacred occasion.

It is with the greatest difficulty and personal inconvenience that we, Your Honour's humble memorialists, have to prosecute our studies here. The extremes of climate of this province, the totally different mode of living, and the extreme trouble in procuring suitable lodgings here, together with the heavy expenditure, all combine to make our stay in Lahore a matter of great sacrifice to our guardians, who are compelled to stay behind at such a distance from us.

Furthermore, an institution like this in the N.W. Provinces will enable such youths to carry on their professional studies, who by reason of circumstances cannot come up here, and consequently are debarred altogether from entering this line.

We, the undersigned, most heartily uphold the scheme, and do consider that it will be a great boon conferred on us and on the community at large, of the North-Western Provinces and Oudh."

ELIMINATION OF MERCURY BY THE MAMMARY GLAND.

THE following communication was made in the Pathological Section at the Thirteenth International Medical Congress, Paris, by M. SIGALAS, of Bordeaux.

M. DUPONG and I have conducted two series of experiments—one on women suffering from syphilis, who have been under specific treatment for several months; the other on a woman and a she-goat who had been given mercury for the purpose.

These researches have led us to conclude, contrary to the opinion of many, that mercury must be counted amongst those toxic and medicinal substances which are eliminated by the mammary gland.

It has to be borne in mind that there is a delay in this elimination, which naturally varies according to the nature

and dose of the product administered, as well as according to the species of animal, the age of the subject, etc. This delay or interval serves to explain the negative results obtained by those investigators who have not succeeded in finding mercury in the milk of animals submitted to this drug, even in large doses.

As regards therapeutics, the fact that mercury is eliminated in the milk proves that the indirect treatment of syphilis in newly born infants by the milk of nurses undergoing a course of mercury is a rational method. But the physician must bear in mind the delay that occurs before elimination begins, and in case of acute manifestations must give the drug direct.

STUDY OF CHEMISTRY IN BOMBAY.

THE *Times of India* says:—Professor RAMSAY, before leaving Bombay, addressed the following letter to Professor GAJJAR, of the Girgaum Techno-Chemical Laboratory:—You asked me on Sunday to put in writing my ideas regarding the chemical work you are doing in Bombay. Well, your laboratory is the only one I have seen in India where commercial analytical work is combined with the training of students. There are many such in Great Britain and the Continent, and, as a rule, they do well, both in furnishing a reasonable income to their chiefs, and in training young men to a practical knowledge of chemistry; and I see no reason why, if you have a reputation for accuracy of work and integrity, you should not be successful. The Institute of Chemistry, of which practically all British analytical and consulting chemists are Fellows or Associates, has done much to raise the standard of education and capacity among professional and consulting chemists. It demands four years of training, besides attendance on lectures on mathematics and physics; it requires either three years' work in certain recognised institutions, such as colleges or universities, or, as an alternative, two years' training in a "recognised institution," and two years in an analyst's laboratory, such as yours. I am sure that you might co-operate with the colleges in Bombay, and, indeed, in the Bombay Presidency, in giving students who wish to take up the career of manufacturing or consulting chemists such a training as the Institute of Chemistry deems necessary.

SUPRA-RENAL GLAND SUBSTANCE IN THE TREATMENT OF BRONCHIAL AND PULMONARY AFFECTIONS.

THE vasomotor constrictor effects of the supra-renal capsules have been utilised in the treatment of asthma with bronchial congestion and in the treatment of gastro-intestinal hæmorrhage.

In the same manner, no doubt, we may account for the good results obtained by this substance by Dr. S. FLORESHEIM, of New York, in certain affections of the respiratory passages, such as acute tracheo-bronchitis, chronic bronchitis, bronchiectasis, congestion and cedema of the lung, hæmoptysis, etc.

In all these diseases the administration of two and a half grains of dried supra-renal substance, in the form of tabloids, produced an amelioration of the symptoms in a few minutes; the cough ceased, the expectoration, the dyspnoea and the physical signs of the lesions (râles, dulness, etc.) improved, the pains disappeared; in cases of hæmoptysis the hæmorrhage was quickly checked.

This action of the remedy, in some cases fairly persistent, is most frequently transitory; further, in order to prolong the effect obtained, it is necessary to repeat the drug every hour, or every two hours, in the same doses of a grain and a half.

PUBLIC COMPLAINT AGAINST THE CALCUTTA MEDICAL COLLEGE HOSPITAL.

The following correspondence appears in one of the leading Anglo-native papers of Calcutta :—

TO THE EDITOR OF "THE INDIAN MIRROR."

Sir,—There is nothing more to be regretted than that the fair fame which had heretofore marked, among others, the Calcutta Medical College Hospital in respect of its treatment of the in-door (Indian) patients by the hospital staff, should suffer, chiefly owing, among other causes, to the high-handedness and unpardonable vagaries of the assistants on duty in the different wards of the said hospital inspired by sheer want of supervision and discipline on the part of the authorities concerned, with the result that the poor Indian patients, who have no resources left to them other than being admitted into the said hospital for medical help, do suffer in a measure which demands the serious attention of the Medical Board, and the public for whose benefit the above charitable hospital has been called into existence. To illustrate the above, I make no apology to publish in your esteemed journal the following correspondence, addressed to the Superintendent of the College Hospital by one Babu BENODE BEHARI BANERJEE on behalf of the aggrieved Babu KADER NATH GHOSAL, aged about 60, of village Gangnapore, District Jessore, who was suffering from ulceration in the *testes*.

Yours, &c., FAIR PLAY.

HUGELY; dated 15th February 1901.

"52, CHAMPATOLA 1ST LANE; Calcutta, 29th January 1901.

To—The Superintendent, Medical College Hospital, Calcutta.

Dear Sir,—I beg to bring to your notice that a patient, seriously affected with ulcers in the testicle, was admitted into Dr. ——— ward on the night of the 18th instant with number 16, bed No. 175. He was under treatment in the hospital for a week and was fairly improving, but on the 27th instant, when my brother went to see him after 11 A.M., he was ordered by Dr. ——— and the nurse of the ward to take the unfortunate patient away without delay. My brother was of course surprised to hear this, and entreated the said Doctor to allow him to remain there until his recovery; but the nurse in charge immediately ordered a palankeen and discharged the poor man without showing any cause whatever. Thus compelled, the poor man was removed to No. 52, Champatola 1st Lane, and there having no sufficient accommodation, was taken away yesterday to his native village, where he is sure to die without any medical help.

As I have been put to great inconvenience and trouble by the unkind orders issued by the said Doctor and the nurse of your charitable hospital, and as the said orders are likely to result in the death of the poor patient, disgracing the glorious fame of your hospital, I shall be thankful to you if you enquire into the matter, and let me know why the poor man was abruptly discharged from the hospital when he was apparently on the way of improving. Soliciting the favour of an early reply.

I remain, Dear Sir, yours faithfully,
(Sd.) BENODE BEHARI BANERJEE."

SINCE our serious and severe comments on the Calcutta Medical College Hospital have been published and brought to the notice of the Government in various ways, there has been considerable official manoeuvring at that great institution. It has been honored by two visits from the Lieutenant-Governor of Bengal, by several from the Inspector-General of Civil Hospitals, and by others from that singularly invisible official, the Director-General, I. M. S. It has been agreed that there is something rotten in the state of Dpdmak, but whether there will be a real cleansing of these Augean stables, is quite another matter. We protest against this hole-and-corner style of dealing with public scandals. There is a great deal wrong with the ~~defect~~ management of this large public institution, and much as the visits of high officials may do towards effecting some good, nothing but a sifting investigation by an independent mixed committee of

officials and non-officials will rid the Calcutta Hospital system of its defective medical attendance and of its old-standing and firmly rooted evils. It is against a system, rather than individuals who work that system, that we complain: Will not the Lieutenant-Governor order such enquiry?

A STORY ABOUT THE QUEEN.

WHILE visiting the wounded at Netley, Her Majesty was greatly distressed by the appearance of one poor man whose face had been terribly injured by the fragment of a shell. "Is there nothing," said the Queen, "that I can do for you?" The soldier replied, speaking with difficulty owing to his injury, "Nothing, Your Majesty, unless you would thank my nurse for her kindness to me." The Queen turned to the nurse, who was standing close by, and said with tears in her eyes: "I do thank you with all my heart for your kindness to this poor wounded son of mine."

UNPREJUDICED TESTIMONY AS TO VACCINATION.

THE State of Georgia is one of the few in the American Union still without a State Board of Health. A Bill has, however, been prepared, authorising the State Medical Society to name four medical practitioners, and the Governor to name five others, who together shall constitute a State Board of Health. Among those who will be sorry to hear this news, we may venture to assume, is a certain transplanted—"aunty" who, when the public vaccinators appeared at her door, exclaimed "O Lawd! I wisht I was back in ol' Georgy. Dey have small-pox der all de time, an' dey don' never vaccinate nobody."

PROTECTION AGAINST BLACKMAIL IN THE UNITED STATES.

A BILL for the protection of physicians and surgeons from blackmail and unjust malpractice suits is, we learn from the *Medical News*, to be introduced into the New York State Legislature this session. Its most important provision will be the requirement of a bond from any one bringing a suit against a medical practitioner for alleged malpractice. This bond is to be forfeited in case the judgment goes against him.

SHORT ITEMS AND PERSONALITIES.

The medical health officers of England are now devoting their attention not so much to water contamination as to beer adulteration. Numerous cases of peripheral neuritis have developed, and the cause has been found to be in the arsemenal adulteration of beer. The resemblance of this neuritis to another form has suggested the name "Beery-Beery" as descriptive of it.

A large increase in the number of deaths from plague is reported. During the week the mortality reached 4,773 against 8,416 in the previous week. The increase is general, save in Mysore. In Patna and Bombay the mortality has risen rapidly. At Karachi the Municipality is unable to meet the expense of plague measures and looks to Government for assistance.

Professor Carl von Noorden says that the century has not produced any single drug which has a decidedly curative effect in diabetes. He speaks highly of several vaunted remedies, and says that their virtue lies in the fact that patients are kept upon a strict diet at the same time that they receive the drugs.

Colonel Lawrie, I. M. S., vacates the appointment of Residency Surgeon, Hyderabad, which he has held for many years, in May next, and will be succeeded by Colonel Gimlette, I. M. S., from Indore. Colonel Lawrie was also Director of the Nizam's Medical Department, the allowance for which is Rs. 1,700 a month.

Surgeon-General Spencer, P. M. O., Punjab Command, will officiate as Director-General of the Indian Medical Service when Surgeon-General Harvey proceeds on furlough next month.

Mr. P. N. Lakshmanan, M.B., C.M., Madras, has passed the D. P. H. of the B. C. P. of London.

WANTED—A POST BY AN ASSISTANT SURGEON willing to serve in a Native State in the Railways or any Municipality, &c. Apply V., C/o The Manager.

Current Medical Literature.

MEDICINE.

Early Diagnosis of Pulmonary Tuberculosis.

BELL (*St. Paul Medical Journal*) emphasizes the importance of obtaining a complete personal and family history of the patient suspected of having tuberculosis. Anal fistula or ischio-rectal abscess should excite suspicion. Clinically tuberculous patients may be separated into three classes: First, a class presenting the symptoms of causeless dyspepsia, gradual loss of flesh, inability to bear exertion, accelerated pulse, slight afternoon rise of temperature, pale or sallow skin, slight cough; later, positive physical signs and microscopic evidence of infection. Second, a class consisting largely of young females presenting at first the symptoms of slight but progressive anemia, loss of flesh and strength, breathlessness on slight exertion, slight elevation of temperature, pulse small, increased in frequency and the arterial tension higher than in cases of primary anemia of the same grade; later, cough, free expectoration, night-sweats and all the "classic symptoms of pulmonary tuberculosis. Third, a not inconsiderable class where the first warning is a hemorrhage or a series of slight hemorrhages without provocation in an individual apparently in perfect health, followed in a large percentage of cases by increased pulse-rate, considerable elevation of temperature and all the other evidences of tuberculous infection. The author says in his experience a dry, harsh, lusterless condition of the hair is of diagnostic value in relation to tuberculosis. Continuous dilation of the pupils, occasionally one more than the other, is a frequent early sign of this disease. A general discussion of the findings on inspection, palpation, percussion, auscultation, thermometry, etc., are discussed. He says of the newer diagnostic methods none give more promise than the serum method of diagnosis. AROLIN and COURMONT claim as high as 100% of reactions in cases known to be tuberculosis.

Treatment of the Optimum Habit by Bromides.

CHURCH now employs the bromides in the following method: The drug is only given during the daytime. For the first day 120 grs. of sodium bromide, dissolved in a tumblerful of water, are given every two hours till 1 oz. has been taken. Next day smaller doses are administered in the same way. In some cases it is necessary to continue the use of the drug for the third day. When it is stopped, the patient is in a very profound state of drowsiness, so that it is impossible to arouse him, or he is incoherent. As the action of the bromide is cumulative, this drowsiness continues to deepen for a day or two after the drug is stopped, and a comatose condition may develop with difficulty in feeding the patient, requiring in some cases rectal alimentation. As one of the chief dangers lies in aspiration pneumonia, feeding has to be very carefully attended to, and CHURCH holds that any septic condition of the mouth or nasal cavities forms a contraindication to the bromide treatment. As sodium bromide depresses heart and respiration, the treatment is dangerous for those with weak hearts or pulmonary complications. CHURCH further reports a case of fatal nephritis which seems to point to an action on the kidney. That the method of treatment is not without danger is shown by the fact that out of twelve cases three died, though the death could only remotely be attributed to the bromide. Still, taking into consideration the difficulties of the ordinary line of treatment, CHURCH thinks that the bromide treatment is of considerable value in properly selected cases, if adequate hospital control can be obtained.—*New York Med. Jour.*

Ulceration of the Stomach.

In the Section of Internal Medicine at the recent International Congress, Professor DIEULAFOY presented a communication, of which the following are the conclusions: There are found in the stomach ulcerations of every size, from the minute punctiform erosion up to large deep ulcers bigger than a five-franc piece. Digestive disturbances, gastric intolerance, vomiting, hæmatemesis, perforation of the stomach with its consequences, and the addition of cancer are symptoms and complications common to many

ulcerations of the stomach. Instead of passing in review each of these symptoms and complications, DIEULAFOY thought it preferable to choose among ulcerations of the stomach a certain number of types representing, from the clinical, pathological and anatomical point of view, sharply-defined morbid entities. As examples of some of these types he gave the following:—(1) Erosion is the smallest of ulcerations, it shows itself on the mucous membrane in the form of hæmorrhagic points more or less numerous. Notwithstanding their minute size, the erosions might cause abundant hæmatemesis. (2) In certain circumstances there are found on the mucous membrane of the stomach one or more losses of substance a little more extensive than erosion. DIEULAFOY has proposed for this lesion the name "ex-ulceratio simplex." However superficial it appears, this ulceration may reach the arterioles running under the muscularis mucosæ and cause terrible hæmorrhages, often proving fatal if treatment does not prevent this consummation. (3) The simple ulcer of CHUVPIERRE (ulcus simplex) is the type of gastric ulcers chronic in evolution and tending to perforation. Hemorrhage and perforation are the complications most to be dreaded. (4) Mention should also be made of specific ulcers of the stomach, due to tuberculosis and syphilis, and possibly, like simple ulcer, leading to hæmorrhage and perforation. (5) It not rarely happens that cancer grafts itself on a ulcer of the stomach. (6) The pathogeny of gastric ulcerations is not yet completely cleared up. Infectious agents, toxic agents, arterial lesions, and changes in the gastric juice must be taken into account. It is possible that an ulceration, quite small at first, may end in ulcer simplex. (7) The treatment of gastric ulcerations is, according to circumstances, medical, specific, and surgical.—*Brit. Med. Jour.*

A Study of the Inoculation Theory of Malarial Fever.

ALBERT WOLBERT states that one may devise either of two methods in studying the relation of mosquitoes to malarial fever; first, to search for the anopheles in its native haunts, and then for the case of malarial fever; or secondly, to find the case of malarial fever and afterwards look for the anopheles. According to observations made by different scientists in various parts of the world, it has been demonstrated that not all genera of mosquitoes are capable of inoculating man or birds with malarial fever. This power so to do appears to rest solely with the different species of the genus anopheles. Studies of the human blood reveal the presence of certain small, round, actively motile, intracorporeal organisms. These grow to full development at the expense of the red blood disc, and subsequently rupture, setting free a number of hyaline bodies that at once re-enter other erythrocytes. These results therefore go to show that the sporozoa or plasmodia of LAVERAN require for their complete existence two biological cycles—one being completed in the body of man, the other being completed in the tissues of the mosquito. Should the mosquito be the only agent in disseminating malarial fever, the destruction of the larvæ or pupæ of that insect would be only one way of getting rid of the disease. MANSON suggests the following methods: (1) To begin by administering quinine for long intervals in all cases of malarial fever, since a single man is a source of infection to a whole locality; (2) to cause all persons suffering with malarial fever to sleep under mosquito netting; (3) to compel all the uninfected to sleep in mosquito-proof houses or beds; (4) to kill by different causticides all mosquitoes entering houses; (5) to destroy all the mosquito larvæ before they reach maturity or the biting stage—to which might be added the destruction of the adult mosquitoes in their places of hibernation; (6) the combination of all these methods.—*Jour. Amer. Med. Assoc.*

SURGERY.

Safest Method of Removing the Appendix.

A. A. WARREN, M.D. (*Lancet*), says:—There are three methods of removing the appendix:—(1) The continental; (2) the English; and (3) DOYEN's, which is best, because it is the simplest and safest.

1. The continental method—that commonly followed by TERRIER, MARTMAN, and most Paris surgeons—is simply to ligature the appendix near its base, resect it with the thermo-cautery, cauterise the stump, and then let it fall back into the abdomen. This method is faulty, because it leaves loose and open in the abdomen the cauterised lumen which, even if effectively cleansed, is almost certain to adhere to neighbouring parts. If effectively cleansed, a peritoneal abscess and generalised peritonitis may result.

2. The English method is to dissect back a collar of peritoneum which is finally stitched over the ligatured stump of the appendix. This method is an improvement on the former, but is also faulty in being more difficult, and in exposing the field of operation to a leakage of the bowel contents in the event of an accidental puncture or opening of the appendix. In the case of an inflamed and diseased appendix this accident is difficult to avoid if attempts are made to strip off the serous covering.

3. DOYEN's method is the best. It is simple and rapid; the appendix is not opened, so infection of the peritoneum by escape of bowel contents is not possible, and in the event of infection and suppuration, the pus must discharge into the lumen of the bowel. The little mesentery of the appendix is first ligatured with a small silk ligature to free the appendix laterally. Then (1) the base of the appendix is gently crushed with DOYEN's small clamp. Almost any forceps suffices for this purpose if strong enough and broad enough to completely occlude the appendix for a breadth of, say, a $\frac{1}{4}$ in.; (2) a fine silk ligature is thrown round the base of the appendix in the furrow left by the clamp; (3) the appendix is removed by the thermo-cautery close to the ligature; (4) a purse suture is made in the serous covering of the cæcum close round the base of the appendix (as this purse stitch is drawn tight, the little stump is invaginated so that all is completely closed); and (5) for safety a second fine silk purse stitch is made and the little pucker of the first stitch is similarly invaginated and the ligature is gently tightened. The result technically is perfect, and this is the most aseptic method of removing the appendix.

Tuberculous Lesions from a Clinical Point of View.

CHRONIC inflammation of a joint in a child or young person, says E. OWEN (*British Medical Journal*), is always tuberculous, except in those very rare cases in which it is due to hereditary syphilis or osteoarthritis.

Tuberculous inflammation may completely destroy a joint, and then leave it solidly and soundly synostosed, without the surrounding tissues or the skin having been implicated.

If tuberculous granulation tissue breaks down into a fluid, that fluid is not pus, and the collection is not, properly speaking, an abscess—unless by bad fortune, or by worse surgery, it has become infected by septic micro-organisms.

The fluid collection is not to be treated as an abscess—that is, by incision and drainage—but is to be opened and emptied, and scraped and cleansed of its unhealthy lining of granulation tissue. Then the wound in the skin is to be completely closed by sutures, firm pressure is to be evenly applied, and the part is to be kept absolutely at rest. The success attending this line of treatment leaves, as a rule, little to be desired, or that for this important advance in practical surgery we are chiefly indebted to the patient

researches of our friends with the smock-trocks and guinea-pigs.

"I have," says the writer, "failed to discover that Iodoform is of any peculiar value in the treatment of tuberculous lesions. At any rate, I have long since discarded it, and I have not noticed any falling-off in the results of my practice in consequence. Iodoform is an irritant and a poison; it is apt to be septic, as germs can grow upon it."

Anthrax successfully treated by Local Injections of Pure Carbolic Acid.

FISHER (*Therapeutic Gazette*) reports a case of anthrax in a man, aged 36, who had been employed as a card-stopper in a large woollen mill. The disease began eight days before admission. When first seen his temperature was 104° F.; he complained of headache and weakness; the tongue was heavily coated and the bowels were constipated. The affected arm was very painful and considerably swollen. On the day after admission 1 drachm of carbolic acid (10%) was injected into and around the eschar on the forearm. On the following day his condition was slightly improved, and 1 drachm of pure carbolic acid was now injected into, around and beneath the eschar. These injections of pure carbolic acid were given daily for the next four days, after which the symptoms had almost entirely disappeared. At no time was carbolic acid detected in the urine, although the patient had had one injection of carbolic acid (10%) and six injections of pure carbolic acid in drachm-doses daily. After three injections the temperature fell to normal, and after five injections the eschar ceased spreading. JAKOWSKY has reported 72 cases of anthrax, all of which were cured by the local injection of carbolic acid.

Treatment of Purulent Pleurisy.

G. MARION emphasises the following points in the treatment of purulent pleurisy: (1) Evacuation as soon as the presence of pus is determined. (2) Avoidance of general anaesthesia, which favors syncope and asphyxia which are comparatively frequent during operation for empyema. (3) The point of evacuation should be at the most dependent spot. (4) The pleura should not be irrigated. The writer gives an account of thirteen cases of purulent pleurisy, not tuberculous, which he has treated. Two patients died during the operation—one from syncope, the other from asphyxia. Probably, if they had not been anaesthetised, the accident would not have occurred. Another died a month after operation from amyloid degeneration of the viscera. His operation had been performed at least two and a half months after the beginning of the pleurisy. Another, who was not operated on till two and a half months after the beginning of the pleurisy, developed a sinus which demanded a second operation. This would undoubtedly have been avoided had the first treatment been early. The other ten patients made a rapid and complete recovery. The bacteriological examination which was made in eight cases demonstrated the pneumococcus in two cases; in one case the staphylococcus associated secondarily with the pneumococcus; in five cases the streptococcus associated with anaerobes.—*La Presse Médicale*.

Differential Diagnosis of Intestinal Obstruction.

Z. BOYLSTON ADAMS says that the differential diagnosis is between obstruction and dysentery, chronic and tuberculous peritonitis, and catarrhal enteritis. From the point of view of treatment, the most important differential diagnosis lies between strangulation and impaction or closure of the intestines, occluding the lumen, whether from within or from without. When palpation under ether fails to disclose the nature of the tumour, the anamnesis is of importance. The family tendency, the fact of injury or of surgical operations, of previous attacks of similar nature, of hernias, reduced or not, of the ingestion of indigestible substances, poisons, etc., should be inquired into. Examination per rectum should never be omitted, and the persistent use of high injections may often accomplish much. The employment of purgatives or opium is misleading and dangerous. When a diagnosis of intestinal obstruction is made, the surgeon should be called in.—*Boston Medical and Surgical Journal*.

OBSTETRICS AND GYNECOLOGY.

Cæsarean Section.

ROBERTS reports a case of CÆSAREAN section upon which he remarks as follows: CÆSAREAN section was performed in this case, because the pelvic cavity was blocked by a fibroid tumour of the uterus, so that the conjugate diameter was reduced to 1½ inches, rendering even cephalotripsy impracticable. The tumour sprang from the posterior wall of the uterus, and it was intended to remove it at the time of the operation, but it was found to be so firmly adherent to the rectum and the sigmoid flexure as to prohibit any further interference. The uterus was not drawn through the abdominal wound until it had been opened and emptied of its contents. This procedure allows of more easy manual compression and thus prevents hæmorrhage; it also facilitates accurate suturing of the uterine wall and a thorough cleansing of the abdominal and pelvic cavities. The sutures used were of silk, and they were passed through the peritoneum, the uterine muscle, and the mucous membrane. No abdominal pelvic drainage was adopted, but the uterus was packed with gauze through the vagina. The acute sepsis which occurred was, in his opinion, benefited by the injection of antistreptococcus serum. The patient's temperature was not normal throughout the day until about six weeks after the operation, after which she steadily improved. The uterus shrunk to a hard mass quite fixed in the pelvis. The child was fed artificially and is healthy.—*Phil. Med. Jour.*

Indication for Operative Interference in Extrauterine Pregnancy.

PROCHOWNICK, in concluding his article upon the Indications for operative interference in extrauterine pregnancy, says that all his observations of the last few years have more and more convinced him that an early and radical abdominal operation is the best and wisest conservatism: that in cases of an intact fetal sac with probable tubal abortion and considerable hæmatocele, or if after a pause a secondary hæmorrhage sets in, he would advise an early radical operation; or if fever is associated with the extrauterine pregnancy, he would urge an operation quite energetically, preferring the abdominal section, as it promises a better oversight of the technique, a more radical cure, while the danger is no greater than by the other way. But if consent cannot be obtained for the radical operation, or if the patient has not come under one's care at a suitable time, the further procedure must depend upon the course of each case. In general, he prefers a conservative course, as he thinks secondary operations give little satisfaction to either patient or physician. Here then lies the field for incision and drainage by the vaginal route.—*New York Med. Jour.*

Condition Three Years after Operation of Fifty Successful Consecutive Ovariectomies.

J. D. MALCOLM, M.D., says:—Of fifty successful ovariectomies performed by him three years or more previously, thirty-two patients were found in really good health, fifty had little to complain of, three were in an unsatisfactory condition, and three had died. Of the fatal cases, one patient died of bronchitis two years after operation, and the two others had recurrences of malignant disease. The author also reports some cases that were refused operation, and a series of fatal cases not hitherto published, of ovariectomy and of operations undertaken when ovarian tumours were supposed to exist.

The study of these and other cases has strongly impressed the author with the importance of an early recognition and removal of ovarian neoplasms. When a tumour is buried deeply in the broad ligament at the beginning of its growth, it is only by the merest chance that its removal will become more easy as time passes. In every case, delay in operating exposes the patient to the onset of complications which may

cause great difficulty and great danger when the abdomen is opened or before an operation is arranged for. When inflammatory conditions are set up around an ovarian growth, the risk is very much greater than it is when there has been no trouble after complete recovery from the operation or inflammatory disturbance. Yet when an operation has been too long postponed, its performance may greatly hasten the fatal issue. An ovarian tumor is sure to give trouble sooner or later, and it should therefore be removed as soon as diagnosticated, if such treatment seems at all practicable.—*New York Med. Rec.*

Method of Inducing Peristaltic Action after a Peritoneal Section.

BYFORD advocates the systematic method of inducing peristaltic action as soon as possible after a peritoneal section. He first used this method for the purpose of preventing intestinal paralysis and adhesions, and he noticed in the cases thus treated a marked improvement in all after-symptoms. There were practically no temperature cases, no crying for morphia, no bloating, no fixed pains, and seldom any subsequent pain in the ovarian regions, even when firmly adherent appendages had been removed. The method advocated consists of 4 drachms of fluid extract of cascara, or some equivalent, 2 hours before the time set for the operation, drachm doses of magnesium sulphate every hour from the time the patient awakes after the operation, and a high glycerin and water enema (2 to 4 ounces) every two hours, beginning eight hours after. A high glycerin enema was given before the patient left the table after operations in which adhesions were separated and raw surfaces left. The treatment must not, as a rule, be discontinued until the patient passes flatus, not only with the enemas, but freely between enemas. Means must be taken to maintain frequent peristalsis, and a daily evacuation of the bowels after the first days. To that end 2 drachms of magnesium sulphate or 2 or 3 ounces of Hunyadi water are given night and morning for two weeks, the dose being regulated according to the effect.

A Plea for more Frequent Avoidance of Exsection of the Ovaries in Connection with Operations upon Diseased Tubes.

PHILANDER A. HARRIS states that less than three years ago he abandoned the routine practice of removing the ovaries with their diseased tubes. He spares as much ovarian tissue as possible. He remembers but two instances in which a surgical menopause followed double-tube amputation or excision during this time. To the woman of respectability, her knowledge that she is not as other women are will be a strong factor in causing her unhappiness. The writer believes that sufficient ovarian stroma may be saved to maintain menstruation and ovulation in at least ninety per cent. of all the bilateral tubal amputations and exsections for the so-called purely inflammatory lesions of and primarily in the tubes, and that a cure of pelvic pains does not depend on the removal of the ovaries, but on a removal of the disease from the fallopian and uterine sinuses. A woman with sufficient ovarian stroma for menstruation and ovulation, but with one tube exsected and the other amputated, is not likely to conceive. Still pregnancy is possible in her case.—*New York Med. Jour.*

Birth after Vaginal and Ventral Fixation.

DR. LIEBER reports the case of a woman, forty-two years of age, who had had a vaginal fixation performed for a retroflexion, and who later gave birth to a normal child. Subsequently the perineum was found to be lacerated, the anterior vaginal wall prolapsed, and the uterus again retroflexed. Ventral fixation and anterior and posterior colpoperaphy were then performed. In the next pregnancy the patient did not feel at all well—nausea and vomiting were almost constantly present. When labor set in, a prolapse of the arm occurred, the cervix lay high in the narrow vagina, and a version upon a dead child was done with the greatest difficulty. The author concludes by praising the ALEXANDER operation as the one most nearly approaching the physiological when the birth act is considered.—*New York Med. Rec.*

PHYSIOLOGY, PATHOLOGY, AND BACTERIOLOGY.

Heller's Albumin Test of Urine.

FURSELL describes the various rings observed in HELLER'S nitric-acid test for albumin, and concludes his article as follows: It would seem after these observations and the demonstrations that in making HELLER'S test three rings are formed: (1) The color ring. This ring forms in practically all urines, whether there is albumin present or not. It is especially marked in concentrated urines rich in coloring matter, and in the urine of patients taking iodide of potassium or salol, or indeed any of the coal-tar products. It is at the point of contact between the acid and urine. (2) The white zone of albumin which forms at the line of contact between the urine and the acid, but always above the dark, constant, color ring. This ring is of a densely opaque white, and I think this is especially the fact when there is but little coloring matter in the urine. If there is a small amount of albumin present, however, as in urine containing pus, the ring is less dense, but nevertheless in close contact with the layer of acid and immediately above the color ring. (3) The urate ring, which forms high above the albumin ring, if albumin is present. The color ring forms at the line of contact of the acid and urine, and the color usually disseminates into the acid below and sometimes into the white albumin ring above. It is always below the albumin ring. The white albumin ring also forms at the point of contact of the acid and the urine; it is wholly in the urine and always above the coloring, though later on it may be somewhat discolored by it. The urate ring, a white thin zone, quickly forms, is far above, sometimes one-quarter or one-half inch above, the albumin ring, and is easily dissipated by heat.—*Jour. Amer. Med. Assoc.*

Modification of the Mosquito Theory.

CHARLES R. GRANDY (*Medical News*) declares that he believes in the potency of the anopheles to propagate the malarial organism, but he also believes that they can and do obtain organisms from other sources than direct from the human blood. He thinks it probable that when feeding on other things than human blood (which seems to be more of a delicacy than a staple article of diet with the mosquito tribe), it also injects the parasites into whatever it is eating. Other uninfected anophelis may take in the parasites directly from this food or water; or the plasmodia, in the form in which they are found in the parotid glands, may be able to live in water or damp soil as other sporozoa do, and later on they may be taken up by other anophelis and be inoculated by them into man. It is also possible that the plasmodia may pass into the water from the bodies of the anophelis which have died in the water after depositing their eggs, and may be taken up in feeding by other mosquitoes. Whenever malarial fever regularly appears, there is found the anophelis. Anophelis breeds only in pools, and not in tube: it is the country mosquito, in contradistinction to culex, which is found in both towns and country. They feed at night. They are most numerous at the time of the heavy dews in August and September. Their larvae feed on algae: hence the theory that stagnant water causes malaria. The two objections to this modified theory are: (1) The malarial organisms have never been cultured artificially: but no other parasitic protozoon has been thus cultured. (2) They have never been found free in nature; but the tiny thread-like organisms are so minute that they could easily escape observation when looked for in water. The writer believes that although there is as yet no positive proof of this theory,

still it comes nearer fulfilling all conditions and answering all objections than any other which he has seen.

Relation of Cholelithiasis to Disease of the Pancreas and to Fat Necrosis.

EUGENE L. OPIE states that the association of these two conditions has been mentioned by a number of writers. When anatomical conditions are favorable, disease of the pancreas may occur as a complication of cholelithiasis when a calculus passes along the common bile duct. The lodgment of a stone near the orifice of the bile duct, where it may at the same time compress and occlude the duct of WISSUNG, is not uncommonly a cause of pancreatic lesions and disseminated fat necrosis. Should a calculus become impacted in this position, the cases reviewed by OPIE show that one of several conditions may result: (1) An individual, usually in fairly good health, with perhaps a history of previous gall-stone colic, is suddenly attacked with pain in the epigastric region, accompanied by vomiting and followed by collapse. Death occurs usually within forty-eight hours, and at autopsy gall-stones are found in the bile passages, while the one which caused the fatal attack may be still lodged in the common duct near its orifice. The pancreas is enlarged, infiltrated with blood, and hæmorrhage may have occurred into the surrounding tissue. Foci of fat necrosis are usually present. (2) A fatal termination may not follow rapidly the symptoms mentioned. Pain in the epigastrium persists, jaundice may be present, and a tumor mass above the umbilicus may indicate a probable lesion of the pancreas. At the end of one or more weeks or months death occurs, often with symptoms indicating the presence of suppurative inflammation, presumably in the neighbourhood of the gland. At autopsy the diagnosis of cholelithiasis is confirmed by the presence of gall-stones in the gall-bladder or in the bile ducts, and occasionally the offending calculus is still lodged near the junction of the common bile duct and the duct of WISSUNG. The pancreas is dry, black, and necrotic, and evidence of previous hæmorrhage may be present. Secondary infection has occurred, and the pancreas lies in an abscess cavity formed by the bursa omentalis. In the wall, and often widely disseminated in the abdominal fat, are foci of necrosis. Since the individual has survived the primary lesion, opportunity has been given for the development of secondary changes in the injured pancreas and neighbouring fat. (3) In certain instances long-continued or repeated obstruction of the pancreatic duct by gall-stones does not cause the acute lesions described, but produces chronic inflammatory changes.—*Amer. Jour. of the Med. Sciences.*

Three Micro-organisms other than Klebs-Loeffler which produce Membranous Angina.

BISSELL (*Buffalo Medical Journal*) says the Bureau of Bacteriology in the city of Buffalo has observed that streptococcus pyogenes, and the micrococcus of sputum septicæmia which belong to the bacteria, and Oidium albicans, which belongs to the group of fungi, are each capable of producing a pseudo-membranous inflammation which macroscopically cannot be differentiated from that produced by the KLEBS-LOEFFLER bacillus. So far as observed in that city, the Oidium albicans has never caused a fatal angina; but at least one death has been caused by each of the other germs named, in both of which cases the antitoxin of diphtheria was used without appreciable effect. Several deaths from the streptococcus pyogenes have been reported in New York City, in which nothing but a bacteriologic examination could distinguish the infection from a true diphtheria. The author draws the following conclusions: (1) Streptococcus pyogenes and the micrococcus of sputum septicæmia can produce membranous angina, accompanied by physical disturbances sufficient to result in death. (2) Oidium albicans produces pseudo-membranous exudates easily mistaken for the KLEBS-LOEFFLER inflammation. (3) The only positive means of determining a KLEBS-LOEFFLER infection is by microscopic methods. (4) From the sanitary standpoint, as regards quarantine, anginae due to streptococcus pyogenes, micrococcus of sputum septicæmia and Oidium albicans require little consideration.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Ought Vaccination and Revaccination to be Obligatory ?

G. LEMIERRE speaks strongly in the affirmative on the subject. Vaccination is obligatory in France for all children. Revaccination is obligatory for all healthy men, but women and invalids are not bound to this obligation. The writer believes that not only vaccination, but revaccination after the end of several years should be obligatory. He quotes GUINON's statement that out of seven hundred and thirty-four nurses employed in the small-pox hospital in London during a period of ten years, only ten were attacked by the disease. These men had not been revaccinated. All the others who escaped had either suffered from the disease or had been revaccinated. As to the interval between the vaccinations, it is now admitted that revaccination should be practised every five years in children, and perhaps a little less frequently in adults after the age of twenty-five years. LEMIERRE, like BROUARDEL, thinks that as a matter of national interest in time of peace, and especially in time of war, vaccination and revaccination should be practised throughout the nation.—*Journal des Sciences Médicales de Lille*.

Therapeutics and Hygiene of Obesity.

AT the recent International Congress at Paris, DESCHAMPS read a paper with the above title (*Le Bulletin Medical*). We should not content ourselves with a mere momentary reduction of weight, but should aim at securing physiological equilibrium between the ingesta and egesta. Diet, calorification, and muscular exercise are the most important elements to consider in the hygiene of obesity. The dietetic regimen should guarantee the patient sufficient food for all his needs, which includes the maintenance of all the gastro-intestinal functions. The regimen of choice is one in which vegetables predominate, and from which farinaceous and feculent articles need not be excluded. Water, pure or slightly alkaline, is the only drink to employ, and enough should be taken to quench the thirst. In certain cases it may be necessary to recommend an excess of water. Physiological calorification plays the chief rôle in reducing the weight of the corpulent. This is effected by prolonged bathing, the temperature of the water ranging from 38° to 36° C., and the duration one to two hours. The static-electric bath is an adjuvant of incontestable utility, as it also favors organic combustion. Muscular exercise cannot be imposed on the obese beyond a certain point. It is useful when regulated, but dangerous when it goes beyond the endurance of the individual. The temporary loss of weight obtained by its agency is more than offset by disorders of function which are set up.—*American Medical Review of Reviews*.

Hygiene and Therapeutics of Puberty and of its Diseases in Woman.

PAUL DALOHE believes that, as far as possible, the young girl at the period of puberty should live at home in order to avoid privation and fatigue. The child cannot have the freedom of air and sun in even the best regulated school that she is free to enjoy at home. The diet should be generous; the meals should be frequent and be composed to a great extent of roasted or broiled meats and wine. Constipation should be avoided. Cold should be avoided at the menstrual epoch, especially in the young. Clothing should be carefully chosen: it should not compress the organs; it should protect efficiently against variations of air and climate. Exercises, gymnastic and other forms, as well as hydrotherapeutic measures, should be intelligently prescribed. Faulty attitudes, so often assumed, should be condemned; if indulged in, they should be corrected. The eyes should

be carefully watched. The author quotes from LAWSON TAIT, who believes in the association of the two sexes. He states that although it may be a pure coincidence, yet he has noticed ovarian hyperemia, especially in young girls who have no brothers, or whose brothers are younger than they. Leucorrhœa is the most frequent and the earliest affection of puberty. It results from the hyperemic state which accompanies evolution of the uterus, and which provokes a hypersecretion of the mucosa; but it is also often an expression of a debilitated condition. This discharge may cause a vulvar eruption. For such a case boiled hot water should be used, the surfaces isolated, and talcum powder applied. The writer lastly considers vulvar pruritus and eruptions with their treatment.—*Bulletin General de Thérapeutique*.

Arsenic and Insurance.

THE Gironde Court of Assizes has devoted several sittings recently to a grave charge of poisoning. The facts were as follow:—A. M. FAYOLLE, of Bordeaux, married a few months ago a young lady of the town, who had a small fortune of about £3,000. She was of delicate health, and shortly after the wedding he obtained a will naming him her sole heir. In addition, he managed to obtain an insurance policy on his wife's life for £8,000. Mme. FAYOLLE died not very long afterwards, and the circumstances being suspicious, a *post-mortem* examination was ordered, which led to the discovery of arsenic in the viscera. The experts came to the conclusion that it was a case of criminal poisoning. On the other hand, evidence proved the medicine Mme. FAYOLLE was taking by the doctor's order at the time of her death contained arsenic, as the prescription showed. But the doses prescribed by the doctor and dispensed by the pharmacist was nothing like the quantity found in the body by the experts after death. Several pharmacists came forward to say that M. FAYOLLE had attempted on various pretexts to obtain poisons from them, and one stated that the defendant had been supplied in his pharmacy with arsenic, on the plea that it was wanted for poisoning rats. The prisoner energetically protested that he was innocent, and as Professor POUCHET, of the Bordeaux Faculty, severely criticised the expert evidence on the ground that it was not conducted on the latest scientific basis, the case was adjourned until the next session.—*Chemist and Druggist*.

Right of Property in Medical Records.

AT a recent meeting of the Society of Legal Medicine, according to the Paris correspondent of *The Lancet*, M. BROUARDEL brought forward a most interesting point in reference to a matter upon which he had been consulted. A medical man died, and his only son, also a medical man, entered into possession of his father's house and carried on the practice. He was anxious to consult certain notes and observations accumulated by his father which were stored away in the consulting room; but his step-mother (*bellemère*) as co-heiress refused to let the son make use of the notes, ostensibly on the plea that she was anxious to avoid any violation of professional secrecy. M. BROUARDEL was of opinion that there would be no violation of secrecy, but simply a continuation of the trust from the first medical man to the second, who succeeded and who would take over the medical observations collected by his predecessor. A legal expert, however—namely, M. DANET—held a different opinion, and thought that all the notes and case-books should be burned. In face of this difference of opinion, the question should be left to the courts to decide. In the course of the discussion at the Society of Legal Medicine, M. LAGRÈNE DE LA CHARRIÈRE gave it as his opinion that a man who sells his practice has no right to communicate details as to the past medical history of his clients, because they may choose to go to some other medical man than the purchaser of the practice. M. ROCHER said that French law did not recognize the sale of practices. *A fortiori*, then, a medical man had no right to hand over to his successor details of patients without their consent. He agreed with M. DANET that the documents should be burned. M. BROUARDEL protested against his view, for, if whenever a practitioner died all his notes were to be destroyed, great injury would be done to the patients themselves, and science would be deprived of a very valuable mine of collected knowledge. The matter was in the end remitted to a special committee, on the motion of M. BROUARDEL.

THERAPEUTICS & PHARMACOLOGY.**Indications for Venesection.**

M. A. ROBIN said that the result of the withdrawal of blood upon nutrition and metabolism must be considered, as well as the mechanical and antitoxic effects of venesection. Researches carried on by the author for years had satisfied him that after bleeding from 150 to 250 grammes (roughly $\frac{1}{4}$ to $\frac{3}{4}$ ounces) in cases of pneumonia, cardiac trouble and uræmia, polyuria was a regular sequence, while the ratio of solids, *e. g.* urea, phosphoric acid and nitrogen, was increased. Pulmonary ventilation was also increased, the increase amounting in one case to 61 per cent. The oxygen used by the tissues was also increased. Similar but less marked changes were also to be seen after hæmorrhage, whether physiological, as in menstruation, or pathological, as in epistaxis, etc. M. ROBIN considered venesection an excellent means to increase cellular oxidation, and that it was indicated whenever nutrition was interfered with by inadequate oxidation, and not by excessive dissimilation.

Treatment of Fever.

In response to the question, Should Fever be Treated? Dr. STOKVIS, of Amsterdam, said that in some cases it was impossible not to interfere. Such, for instance, as when the patient was in danger of collapse from alarming conditions arising from the heart, respiratory organs or nervous system. As to the mode of intervention, Dr. STOKVIS thought the attempt to reduce fever by antipyretics a great mistake, and that hydropathetics and analeptics should alone be had recourse to, although medicines might occasionally be profitably employed to ward off impending collapse. This was the case in those diseases in which specific medication was possible, as in them the disease itself, as well as the pyrexia, could be combated. Except in malarial disease, however, and acute rheumatism, specific medication was not yet possible. Dr. STOKVIS, therefore, considered that nursing, rather than the treatment of fever, was necessary in most cases, and that diet and regimen, rather than drugs, were needed in such diseases.

Some Statements concerning Calomel.

THE new Italian journal, the *Practica del medico*, says:—That the fact that certain erroneous notions about calomel, especially its incompatibility with other drugs and the danger of its transformation into corrosive sublimate, are widely entertained, has led it to make the following statements:—(1) Calomel cannot be changed into corrosive sublimate in the short time for which it remains in the alimentary canal; it is a very stable salt, and only small quantities are transformed into soluble aluminates. (2) Purgative doses are quickly eliminated with the feces, while small fractional doses remain in the intestine for a long time, and, being changed into soluble salts, may be absorbed; this is the reason why calomel in small and repeated doses is more dangerous than in a single large dose. (3) Substances which contain sodium chloride are not incompatible with calomel; those containing hydrocyanic acid (such as cherry-laurel water and emulsion of bitter almonds) are incompatible with it, because they lead to the formation of mercury cyanide, which is very soluble and rapidly absorbed. (4) It is dangerous to administer calomel which has been for a long time mixed with powdered sugar. (5) Calomel should be kept in opaque and well-stoppered bottles, for under the influence of light and air it partially decomposes. (6) Calomel should be in the form of an amorphous powder, fine to the touch, and of uniform whiteness.

Chrysarobin in the Treatment of Hemorrhoids.

POUNNE (cited in the *Journal des praticiens*), who has employed chrysarobin successfully in the local treatment of hemorrhoids, gives the following formulæ:—

R	Chrysarobin	1 grain.
	Iodoform	0.08 "
	Extract of belladonna	0.015 "
	Cacao butter	30 "
M.	Make a suppository.	Two or three such suppositories to be used daily.	
R	Chrysarobin	22 grains.
	Iodoform	8 "
	Extract of belladonna	15 "
	Vaseline	6 drachms.
M.	Make an ointment.		

Correspondence.**MEDICAL REGISTRATION FOR INDIA.**

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—In these days of fraud practised by quack practitioners under the cloak of bogus American M.D. degrees, medical registration seems to be the only safeguard and the only protection of society. This is a subject in which every physician should be interested, both as a physician and as a citizen. As a citizen, because the laws governing the right to practice medicine are essential for the protection of society; as a physician, because, without the protection of proper laws, men of attainments in this branch of science are put upon a level with fraud and charlatans.

Whenever restrictive registration has been attempted in this country, immediately the cry of monopoly has been raised, and so effectively, that for many years legislation was delayed. The matter of medical legislation is therefore a delicate one from a professional standpoint. Dr. MYERS, in his address before the "Mississippi Valley Medical Association," remarked that "there is a feeling in the community and on the part of legislators that in some way the medical profession wishes to put a fence around the practice of medicine in order that those who are in the inside may fatten." It is persistently charged that we want to create a medical oligarchy, to which only a few shall be eligible, and that we desire to limit the number of medical men, so that we alone may occupy the chosen field. These charges emanate chiefly from those whose interests are identical with the diploma mills and the various forms of quackery. The profession urges medical legislation, not from selfish and interested motives, but in the interest of the public health. Those who pose as practitioners of the healing art should be in effect what they claim—masters of medical science. It is the duty of Government to ascertain the qualifications of medical men who pose as medical practitioners in the city and in the mofussil. So far as we are personally concerned, we attach little or no value to medical registration, because they are not necessary for our protection, but we are anxious for the protection of the public.

It cannot be denied that legislation cannot educate people to the necessity of recognising those who have ability and those who have not. It is for this very reason that registration is necessary. You cannot make people honest or moral, therefore laws are necessary to punish theft and protect the community from immorality. And although you cannot by law enact as to what physician, or what class of physicians, or what means of skill, medical or otherwise, people may choose to employ for the cure of their ailments, it is right and proper that registration should be passed, protecting the community from the deplorable consequences of ignorance in all matters pertaining to the cure of the sick. We are no advocates for any undue interference with the personal liberty of the individual adult in full possession of his faculties to get his treatment in disease done for him anywhere and by any method that pleases him, but we want to guard him only against the pestiferous and unscrupulous

charlatany and malpractice. The misunderstanding and the erroneous impression that exist among some of our educated countrymen, that quacks are of some use, at least in the far mofussil, have been weighed in the balance and found wanting. The misunderstanding has rather proved to be the bane of human species, not only in this country, but in all parts of the world. Every man, woman or child has a right to protection from the vagaries of fanatic, quacks and impostors. Mr. Justice FIELD, of the Supreme Court of the United States, in delivering judgment in a case, remarked:—The power of the State to provide for the general welfare of its people authorizes it to prescribe all such regulations as in its judgment will secure, or tend to secure, them against the consequences of ignorance and incapacity, as well as of deception and fraud. Few professions require more careful preparation by one who seeks to enter it than medicine. It has to deal with all those subtle and mysterious influences upon which health and life depend, and requires not only a knowledge of the properties of vegetable and mineral substances, but of the human body in all its complicated parts, and their relation to each other, as well as their influences on the mind. The physician must be able to detect readily the presence of disease, and prescribe appropriate remedies for its removal. Every one may have occasion to consult him, but comparatively few can judge of the qualifications of learning and skill which he possesses. Reliance must be placed upon the assurance given by his license, issued by an authority competent to judge in that respect, that he possesses the requisite qualifications. Due consideration, therefore, for the protection of society may well induce the State to exclude from practice those who have not such a license, or who are found upon examination not to be fully qualified. No one has a right to practice medicine without having the necessary qualifications of learning and skill, and the statutes only require that whoever assumes by offering to the community his services as a physician, that he possesses such learning and skill, shall prevent evidence of it by a certificate or license from a body designated by the State as competent to judge of his qualifications."

Yours, &c.,

HURRO NATH ROY, L.M.S.

ASSISTANT SURGEONS AND THE I. M. S.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—*The Tribune* of Lahore says:—

An evidently inspired paragraph, put into circulation by some of the Anglo-Indian dailies, has caused a flutter of excitement and expectation in the circle of Indian private practitioners and Assistant Surgeons, not unmixed with displeasure in certain quarters. The paragraph is to the effect that in order to relieve the extra strain put on the Indian Medical Service on account of famine, plague and war, Government has decided to employ 20 private medical practitioners for a certain period, reserving to itself the power to terminate the agreement on one month's notice. The pay offered is Rs. 600 a month for those holding the diploma of Public Health

of some British University, and Rs. 500 for Associates of Home medical institutions not so qualified. "A few openings," it is added, "may also not improbably be found for retired Military Assistant Surgeons holding the necessary diplomas." It is not given out as yet whether the new hands will be put on military or on civil duties, but the probabilities are that they will be made to fill vacancies at civil stations. The proposed arrangement is a good idea in so far that it promises a chance to other qualified medical men in India for showing their capacity for public medical work than the favoured members of the I. M. S., but three questions naturally suggest themselves:—(1) Why is the selection to be restricted to diploma-holders of British Universities and medical institutions? (2) Why are the claims of *Civil Assistant Surgeons* (the majority of whom are of course natives of India) left out of consideration? (3) Why not fill the vacancies by holding a competitive examination open to all medical graduates practising or employed in the Subordinate Medical Service in India? A natural corollary to the third question is—(4) Why not hold the competitive examinations for the Indian Medical Service simultaneously in England and India, and thus stop the growing difficulty of finding a good supply of qualified men for the higher grades of the Medical Service?

It is one of the few things, admitted by even the enemies of the educated Indian, that the graduates of the Indian Medical Colleges are as well educated as the best of the medical diploma-holders of England, and that an Indian M. B. or M. D. has received a superior training and passed more difficult tests than holders of British licenses, such as the L.R.C.P., L.R.C.S., L.S.A., &c. Indeed, with perhaps the simple exception of the London University, no other medical examining Board in the United Kingdom requires a higher degree of discipline and training for obtaining its diplomas than the Medical Colleges of India, and, compared with the majority of the former, the standard of tests fixed by the latter is decidedly more difficult. The tendency is to make the conditions of training, as well as of passing, stiffer and stiffer in the Indian Medical Colleges generally, and to allow as few to graduate as possible. Why not then give such of the men as survive the hard process and get their diploma after all a chance to compete for the higher appointments in the public Medical Service and show their capacity in other ways? It is admitted that the resources of the I. M. S. have been taxed to the utmost of late, and that the attractions of the service having lessened in many respects, a supply of first-class candidates is not available for the competitive examinations in London. Alike in the interests of the service, therefore, as well as in justice to the Indian Medical Colleges, the higher appointments, at least in the Civil Department of the Medical Service, should be thrown open to Indian competition by simultaneous examinations being held in England and India. There is a hue and cry after "bogus M. Ds." in which the Government of India has taken part, but what adequate reward has Government in prospect for those who qualify for medical degrees in India under the hard conditions referred to above? A respectable proportion of the American diploma-holders

in India are men who have had the full course of training in one or other of the Government Medical Colleges, and have been prevented from graduating simply by the difficult conditions of the examinations. And if the authorities go on stiffening the tests on the one hand, while on the other hand they limit the field of suitable employment for those who graduate even under such hard conditions, they indirectly create an inducement for getting the foreign degrees over which they profess to be so very indignant.

Yours, etc.,
PANJABI.

OFFENSIVE AND DANGEROUS TRADES: DANGER FROM "DHOBIES."

TO THE "EDITOR, INDIAN MEDICAL RECORD."

Sir,—The remarks which follow are a digest of an article from the *Indian Municipal Journal*:—Section 188 of the Madras District Municipalities Act of 1884 provides for the issue of licenses for offensive and dangerous trades. In many of the mofussil municipalities, no doubt, licenses are given under this section, collecting a certain fee for each license. After obtaining the license, the licensees carry on their trade, in a don't-care fashion, according to their own free will and pleasure, though the result may be one rendering the surrounding atmosphere foul, making the soil filthy, producing unwholesome articles of food, or contaminating any neighbouring source of water-supply, or may be the pukka means of spreading any virulent epidemic. The Municipal Executive are very careful in collecting the required fee for all the licensed places where offensive and dangerous trades are carried on, but, on the other hand, they generally ignore the fact that Section 188 is introduced solely for the health and safety of the public. It has been repeatedly pointed out by the Sanitary Commissioner for Madras that all licenses issued under Section 188 should bear upon the back a statement of sanitary conditions requisite to be satisfied by the licensees before and after issuing the license. In its order No. 757 M., dated 26th May 1899, the Government plainly says: "It should be always borne in mind that the system of licensing certain trades, provided for under the Act, has in view the enforcement of sanitary rules, and not the collection of revenue." It is, therefore, necessary that every license given for any offensive and dangerous trade should bear certain sanitary conditions to be satisfied by the licensees.

For instance, let the trade of a dhobie (washerman) be taken into consideration. A dhobie collects the soiled clothes from his customers' houses, heaps them all together, and stores them in his house, side by side, with the already washed ones. Clothes of patients suffering from any infectious disease are also collected without being previously disinfected, and are heaped together with those of the others that are free from any disease. Thus the disease is introduced first among the members of the dhobie's family, who then become the centre for the spread of the disease.

The connection of cholera, small-pox, plague or such between a dhobie and his customers can be traced, infection being due to the customers sending clothes to the dhobie without washing or disinfection. He takes all the soiled clothes together to the washing place, and

there washes the same in shallow pools of stagnant and filthy water situated in an out-of-the-way corner of the town. This water is used by many who resort to the neighbouring fields or plains to answer calls of nature, or for the performance of ablution. In such a pool of water the dhobie washes the clothes of his customers. The stone on which the clothing is beaten is not far away from the pool, but is kept on the bund of the pool, so that the washed-water may again enter into the pool, and thus cause no diminution in the quantity of the pool-water. Such washed clothes are then dried on the surface of any adjoining field or plain filled with the refuse of decomposing defæcations. This is the way how the dhobie of this presidency deals with the clothes of his customers. Imagine what imminent danger there lies in this trade! Is not, then, the calling of dhobies one that immediately concerns the public health, and so is it not necessary that such a trade should be carefully watched by the Municipalities which are the custodians of the health of their rate-payers?

Now to prevent this evil, the best remedy is for the municipality to have a check on the dhobies by constructing a public dhobie-khana and by hiring dhobies for washing the clothes of the public, from whom a certain fee may be collected by the municipality to meet the cost of payment to the dhobies. If this is impracticable, another remedy is to compel the dhobies to store and wash the clothes only in the public dhobie-khana constructed by the municipality or only in the place selected by the municipality from a sanitary point of view. If the latter also is impracticable, on account of want of funds, which is the usual cry in all the municipalities, a third remedy is to fix certain sanitary conditions to be observed and satisfied by the dhobies, who should be legally compelled to take out the municipal license either with fee or without fee, according to the circumstances of the dhobies. When the dhobies are obliged to take out a license, there comes the fear of strike among them. Of course an obstacle precedes a good thing. How to overcome this difficulty is a question which approaches the purse of the municipality to a little extent. If some other men are employed, on a certain monthly pay, for a certain period, and the clothes of the public are washed by these men, while enforcing the legal penal provisions over the ringleaders of those that struck work, it is certain that, within a short time, the dhobies will be brought to the point. The following conditions may be fixed to be observed or followed by each licensed dhobie:—

(1) The dwelling rooms of dhobies shall not be also the places for the storage of clothing.

(2) There shall be two separate rooms or places so as to keep soiled clothes in one and the washed ones in the other.

(3) Walls of the premises shall be whitewashed, both internally and externally, once in six months.

(4) Each licensed dhobie shall keep a list showing the names and residence of his customers, and this list shall be produced whenever he is called on to do so.

(5) The soiled clothes of each family shall be well boiled or subjected to the process of steam before being mixed with those of the rest.

(6) No clothing of patients affected by cholera, small-pox, plague, or any contagious disease shall be taken by a dhobie unless it is previously disinfected by the municipal authority.

(7) The clothes shall not be washed in filthy water, or dried in any filthy place.

(8) The stones on which clothing is beaten shall be at a distance of 30 yards or more from the water source to prevent the washings entering into the same.

(9) The tank, pond, pool, or well used by a licensed dhobie shall be protected all round to prevent the surface washings entering into the same.

(10) No person suffering from any infectious disease, or being in contact with the persons so suffering, shall wash or in any way come in contact with the clothes.

Yours, &c.,

INDIAN SANITARIAN.

COMPLAINTS OF HOSPITAL ASSISTANTS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—I am desirous of bringing to your kind notice certain complaints of the Civil Hospital Assistants who served in the recent famine in the districts of the Punjab, in the hope that the grievances narrated will catch the eye of a responsible official who will deign to assist us. It is undoubted that the Civil Hospital Assistants as a class supply a real want, and their services are perhaps more meanly remunerated than any other similarly situated class in any other department under Government. Whenever an attempt is made to better their position by a memorial, either no heed is given to their prayer, or they are told that there is a want of funds, caused by famine or plague. It is difficult to see how, under these circumstances, Government can expect the right sort of men to enter this department. Take for instance the treatment meted out to us in the recent famine relief works, with special reference to the Hissar district. Girdawar Quanoongos and Hospital Assistants were employed on these works from the civil and medical departments—both generally draw equal salaries in their respective grades; but here Hospital Assistants were granted a famine allowance of Rs. 5 only, not solely for the extra hardship endured, but also as a compensation for any loss of income by private practice, whereas Girdawars were paid Rs. 50 instead of Rs. 25 as salary, with an allowance of Rs. 15 to Rs. 20 per month, at a time when there was a scarcity of money in the Government Treasury. The duties of Hospital Assistants at these works were: (1) Daily inspection of the sanitary condition of the camp. (2) Distribution of medicines to different gangs at different places. (3) Dressing of in-door and out-door patients. (4) Distribution of medicines to in-door and out-door patients at the dispensary. (5) Distribution of special diets to the adults and weak children, numbering not less than 150, twice a day. (6) Negotiations for the diet with the *bania* and the *lumbardar*. (7) Inspection of small-pox hospital and cholera camp at a distance of about a mile away. These duties

had to be performed in a camp with 10,000 souls, and all without the help of a compounder. I need scarcely say more.

Yours, &c.,
A SUFFERER.

24th January 1901.

ON CIVIL ASSISTANT SURGEONS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—I see "TOMTIT, M.B.," has taken the trouble to reply to my remarks anent Civil Assistant Surgeons.

Beyond the remarks I am about to make with reference to his letter in your issue of the 13th instant, I am not going to enter into the subject again. It is pleasing to note that he has taken my first letter in the same kindly spirit in which it was offered. I repeat, that my sympathies in many respects run with the class he advocates, and personally, I should feel pleased if the prospects of the men looked brighter; at the same time it is folly to gloss over the points raised in the manner "TOMTIT, M.B.," has done. Do not blame Professors and the Government: they have done their duty. It is home influence and home bringing up that needs reformation. Any native of moderate means can have his son educated and admitted into the grade of Civil Assistant Surgeon; but that man's home influence and his life are not those of a *gentleman*, such as we understand the term to mean. It is a case of the silken purse and the sow's ear over again.

That there are men in the Civil Assistant Surgeon class fit to take charge of a district I admit; but they are very few, and very far between—I mean not only professionally, but *socially*, and until native lads are so brought up and educated as to be able to take their places in society and to be thoroughly trusted, the Government is wise in not allowing them to be classed with other officers of districts and their wives, and in having them placed under European supervision. This is where the Military Assistant Surgeon has the preference; he is European by birth, bringing up, intelligence, and easily takes his place in European society, and as a military man knows what discipline is and can maintain it.

"TOMTIT, M.B.," is a first-class advocate, but no amount of controversy can change FACTS, and the sooner the native Assistant Surgeons adopt his mode of thought, act in accordance, and reform their social condition of life, the sooner will they attain what he for them is striving to obtain.

His advocacy at present may only lead to further discontent and to prigs assuming injured attitudes.

Yours, &c.,
LIEUT.-COLONEL, I.M.S.

IN FAVOR OF CIVIL ASSISTANT SURGEONS.

I.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—The Civil Assistant Surgeons are extremely obliged and grateful to "TOMTIT, M.B.," for his able and exhaustive exposition of their grievances in the correspondence columns of your journal, and are highly amused

by the perusal of the instructive, but unfair, remarks made by an experienced officer of the rank of "Lieut.-Col., I.M.S." They are, however, obliged to "Colonel Sahab" for his kindly pointing out practical hints for their improvement, and undoubtedly these will have a salutary effect if every one of the Civil Assistant Surgeons takes them to heart.

They thank "Tomtit, M.B.," sincerely for his admirable, impressive, and appropriate reply to "Colonel Sahab's" remarks, and hope the latter will gain more "experience" by its perusal, and will not be sorry for what he wrote in an unguarded moment.

Yours, etc.,

AN ASSISTANT SURGEON.

II.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—I and many of my grade are very sorry to find the defence made on our behalf by "Tomtit, M. B. No doubt he thinks he is doing us good, but we feel he is injuring us. He does not express our views: those of us in the service of Government are quite content to fight our own cause in the proper way, and to abide by orders laid down for us. That there is much room for improvement in our positions, we plead but time, and time alone will lead to better results than those we have already obtained. We are not lowered by being placed under the orders of Civil Surgeons who are of the Military Assistant Surgeons class, and instead of some of them having to "sit at our feet for years," there is much that we learn from them, as, as a rule, they are officers of fifteen or twenty years' civil experience and practice; and those of us serving under them never have reason to complain of their treatment to us. They are gentlemanly and kind, and give us more than we ever get from I. M. S. officers. "Tomtit, M. B.'s" defence of us as a class is *not required*, and we hope that he will refrain from advocating our so-called grievances."

Yours, &c.,

L. M. S., CIVIL ASSISTANT SURGEON.

USE OF SUPRARENAL CAPSULE IN HEART DISEASE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—I intend to publish a second paper on the use of the suprarenal capsule in organic heart disease.* Will you kindly ask the readers of your journal to send me the reports of their cases as follows:—

I. The condition of the heart and pulse, and also the pulse rate.

II. The effect on the heart and pulse, and also the pulse rate, within ten minutes after the suprarenal powder, three grains, is chewed and swallowed without water by the patient.

Yours, &c.,

SAMUEL FLOERSHEIM, M.D.

218, EAST 46TH STREET, NEW YORK CITY, U. S. A.;

18th January 1901.

* For first paper, see *New York Medical Journal*, 6th October 1900, pages 881-88.

MEDICAL TRADE NOTICE.

VIBRONA DATE-CASES.

Messrs. Fletcher, Fletcher & Co. (Limited), Holloway, N., have sent us specimens of two date-cases which they are issuing. One of them is made to hang, and has a pocket for loose papers and a multiple-tablet for memoranda at the side of the monthly calendar. This case is sent on application to chemists who are doing a good business in Vibrona. The other case is for standing upon the writing-table, and has been specially got up for medical men. Each month's calendar is printed on a double sheet of art-paper, and each of these bears a midget reproduction of a "Vibrona Art-series" picture with particulars about the series. The cases are good, and are a pleasing compliment to Vibrona, which is making steady headway with the profession and the public as a reliable tonic-wine that does not encourage secret tipping.

Government Medical Gazettes.

BOMBAY.

The undermentioned lads are admitted into the Grant Med. Col., Bombay, as Milly. Pupils:—

William Earnest Cody; Frederick Osmond Wade; Edward Demosthenes Lobo; Grant Ruth Atkins; Alexander Leslie Hudson; Roland William Christopher McEvoy; Clarence Archibald Wells; Charles Bernard O'Brien; Herbert De-Penning; Louis Duckworth Ruth Atkins; Harold Augustus Young; Arthur William Hazel; Henry Blessington Vincent; Dermot Edwin Lawrence.

The services of the undermentioned Hosp. Assts. are tempy. lent to this Presy. under the orders of the Govt. of India for famine duty and travelling dyspepsia, and are placed under the orders of the San'y. Commer. for the Govt. of Bombay:—

Sadaswim Pillay; Mohamed Abdul Aziz; Romesh Chandra Ghosh; T. Appanba Naidu; Ekbal Hussein; Amritlal Bannerji; Rooh Behari Sen Gupta; Shahadul Hug; Devendro Kumar Bose; Babu Sitapati Chaturji; Nimai Charan De; Hari Charan Sil; Bhagat Prasad Ghose.

The undermentioned Hosp. Assts. belonging to the Milly. Dept. (tempy. lent to the Civil Dept.) have reverted to Milly. duty and reported their departure on the dates mentioned opposite their names:—

Bengal Presidency.

Senior Hosp. Asst. Kataru Ram, 24th Sept. 1900; Lashkari Parshad, 7th Aug. 1900.

First Grade Hosp. Assts. Alah Banda, 20th July 1900; Natthu Mal, 21st July 1900.

Second Grade Hosp. Asst. Mansingh, 21st Sept. 1900.

Third Grade Hosp. Asst. Tarachand, 22nd Sept. 1900; Hira Nand, 22nd Sept. 1900.

Bombay Presidency.

First Grade Hosp. Asst. Lingra Bajana, 24th Sept. 1900.

Second year native Milly. Pupil Gangaram Viaram, Byramji Jijibhoy Med. School, Ahmedabad, is dismissed from the school.

The undermentioned Hosp. Assts. were relieved from famine duty under the orders of the Sany. Commr. for the Govt. of Bombay and directed to proceed to Cuttack, travelling under the usual conditions, and, on arrival, to report themselves to the Supdt., Med. School, Cuttack. They reported their departure on the date mentioned against their names :—

Ramchandra Ghosal, 12th Nov. 1900; Keshori Mohun Mojumdar, 12th Nov. 1900; Radha Mohun Chakravarty, 6th Nov. 1900; Bamesh Chandra Ghosh, 6th Nov. 1900.

CENTRAL PROVINCES.

Civil Hosp. Asst. Konj Behari Lal, attached to the Brahmapuri Branch Dispy., Chanda Dist., held ch. of the famine relief kitchen at that stn., in addn. to his own duties, from the 10th June to the 28th Nov. 1900.

Civil Hosp. Asst. Pranaukh, attached to the Warora Branch Dispy. in the Chanda Dist., held ch. of the relief kitchen at that stn., in addn. to his own duties, from the 9th June to the 1st Dec. 1900.

Civil Hosp. Asst. G. Ramaiya Naidu, who was in ch. of the Venkatapur Branch Dispy. in the Chanda Dist. held ch. of the relief kitchen at that stn., in addn. to his own duties, from the 4th April to the 31st May 1900.

Civil Hosp. Asst. G. Ramaiya Naidu, attached to the Stroncha Branch Dispy. in the Chanda Dist., held addnl. ch. of the relief kitchen at that stn. from the 8th June to the 31st Oct. 1900.

Civil Hosp. Asst. Saiyid Sallar, attached to the Venkatapur Branch Dispy. in the Chanda Dist., held addnl. ch. of the relief kitchen at that stn. from the 31st May to the 31st Oct. 1900.

Civil Hosp. Asst. Vasudeo Ganesh, attached to the Allapilli Branch Dispy. in the Chanda Dist., held ch. of the relief kitchen at that stn., in addn. to his own duties, from the 25th Nov. 1899 to the 28th Oct. 1900.

Civil Hosp. Asst. Baliram Dadaji Deo, attached to the Pandaria Branch Dispy. in the Bilaspur Dist., is granted two months' privilege leave, from the date on which he is permitted to avail himself of it.

Civil Hosp. Asst. Maroti Ramkrishna, on gen. duty at Nagpur, is apptd. to the Pandaria Branch Dispy., Bilaspur Dist., during the absence, on leave, of Baliram Dadaji Deo.

Privilege leave for one month is granted to 2nd Class Civil Hosp. Asst. Balaji Baliram, attached to the Kothi Bazar Branch Dispy., Hoshangabad, from the date he is permitted to avail himself of it.

Leave on med. certificate for one month is granted to Civil Hosp. Asst. Kshirode Kumar Ghose.

Civil Hosp. Asst. Surji Rao, on gen. duty at Nagpur, is granted three months' privilege leave from the 1st Feb. 1901.

Civil Hosp. Asst. Pandurang Lakhshman, doing gen. duty under the orders of the Civil Surgn., Nagpur, is transferred to Betul to take tempy. ch. of the Branch Dispy.

On relief by Civil Hosp. Asst. Pandurang Lakhshman, Civil Hosp. Asst. Ramkrishna Balwant of the Betul Branch Dispy. is granted two months' privilege leave.

Civil Hosp. Asst. Muhammad Inamullah, on gen. duty in the Saugor Dist., is directed to hold tempy. ch. of the Multai Branch Dispy. in the Betul Dist.

Privilege leave for three months is granted to 3rd Class Civil Hosp. Asst. Jaiiram Bhan Sonwalkar, in ch. of the Multai Branch Dispy., from the date he is relieved by Civil Hosp. Asst. Muhammad Inamullah.

Private Hosp. Asst. Upendra Chandra Sirkar was employed on famine duty in the Civil Dept. in the Chanda Dist. from the 21st Oct. to the 5th Nov. 1900.

Six months, leave without pay is granted to 2nd Class Civil Hosp. Asst. Abdul Karim, attached to the Balhar Branch Dispy. in the Balaghat Dist., from the 9th Oct. 1900.

Civil Hosp. Asst. Anandram Nandra, on gen. duty at Raipur, is granted one month's privilege leave from the 5th Feb. 1901.

MADRAS.

The services of the undermentioned offrs. are replaced at the disposal of the Government of Madras :—

Capt. W. C. Vickers, M.B., I.M.S. (Madras).

Capt. C. B. Harrison, M.B., I.M.S. (Madras).

Major Robert Robertson, I. M. S., to be Surgn, Second Dist. and Supdt., Voluntary Venereal Hosp., Madras, *sub. proutem*, from the 28th Dec. 1900.

Capt. Wilfred Constant Vickers, M.B., I. M. S., to act as Dist. Med. and Sany. Offr. with med. ch. of Central Jail, Coimbatore, during the employment of Major D. Simpson, I. M. S., on other duty.

M. R. By. Pondicherry David Savarinatha Amirthasami Pillai Avargal to act as Civil Surgn., Tellicherry, during the employment of Major R. Robertson, I. M. S., on other duty.

Capt. C. Donovan, I.M.S., privilege leave for three months, from or after the 1st March 1901, Civil Service Regulations, and furlough on med. certificate for nine months under article 340 (a), Civil Service Regulations.

Lieut.-Col. William Alexander Lee, I. M. S., to act as Dist. Med. and Sany. Offr. with med. ch. of Central Jail, Trichinopoly, during the employment of Lieut.-Col. W. F. Thomas, I.M.S.

BURMA.

Hosp. Asst. Gajan Singh, on return from leave, assumed ch. of his duties with the Mily. Police detachment proceeding from Thazi, Meiktila dist., on the 19th Dec. 1900.

Hosp. Asst. Gajan Singh relinquished ch. of his duties with the Mily. Police detachment at Taunggyi, Southern Shan States, on the 31st Dec. 1900, and assumed ch. of his duties at the Civil Hosp., Taunggyi, Southern Shan States, on the 31st Dec. 1900 as a supey.

Hosp. Asst. Gajan Singh relinquished ch. at the Civil Hosp., Taunggyi, Southern Shan States, and assumed ch. at the Civil Dispy., Thamekhan, Southern Shan States, on the 5th Jan. 1901.

Hosp. Asst. Gajan Singh assumed ch. of additional duties at the Police Hosp., Thamekhan, Southern Shan States, on the 5th Jan. 1901.

NOTICES TO CORRESPONDENTS.

"John Brown."—Your letter received; contents noted. M. Ostermayer & Co. (Bombay).—The parcel has not been delivered to this office by the railway authorities.

J. M. P. (Aden).—Your papers have been forwarded to the authorities.

Col., I. M. S.—We are bound to give "Tomtit, M.B." the fullest opportunity to reply to your strictures. We consider that he has written well and temperately.

F. H. A. (Bander).—The case you write about is a distressing one. Seek advice nearer home. We cannot advise you in such a case without seeing your patient.

A. B. C. (Hyderabad).—Gat Parkes' and Haswood's work on "Hygiene and Public Health."

ORIGINAL ARTICLES.

THE SURGICAL TECHNIQUE AND OPERATIVE
TREATMENT OF ELEPHANTIASIS OF THE
GENERATIVE ORGANS BASED ON A
SERIES OF ONE HUNDRED AND
FORTY CONSECUTIVE
SUCCESSFUL
CASES.

BY MAJOR R. HAVELOCK CHARLES, M.D., M.CH., F.R.C.S., I.,
Indian Medical Service.

*Professor of Surgical and Descriptive Anatomy and
Clinical Surgery. Surgeon, Medical College
Hospital, Calcutta.*

It is possible that to some, certain of the points touched on may seem unnecessary and self-evident; but, as this is written for Surgeons, both European and Indian, commencing the operative treatment of the disease, I have thought 't best to be clear at the risk of being verbose. My experience as a teacher for many years has shown me that senior students, and those beginning practice, more often fail in attention to detail than in the greater things necessary! "*Haud ignara mali miseris succurrere disco.*"

In January 1897, I read before the Calcutta Medical Society a paper on "A New Method of Operating in Elephantiasis Scroti," publishing then the results of a series of 60 consecutive successful cases. Since then I have operated on a further series of 80, thus completing 140 consecutive cases without a death.

This more extended experience has led me to modify certain of my original methods, and, as I have received letters from various Surgeons interested in such operations, asking for details, I venture now to bring the subject again before the profession.

The operation being one of expediency, necessitates the most scrupulous attention and care to technique and treatment, as a fatal result is more to be deprecated than in conditions of surgical emergency.

THE CHARACTER AND CONDITION OF THE PATIENTS
that have come to me for relief have differed much.

In age they have varied from 16—62 years. Some had health in good store: in others the shattered frames, worn with digestive troubles, showed livers and spleens enlarged from malarial cachexia. In appearance the pendulum has swung from the emaciated famine type to the individual with pendulous belly and elephantine gait.

The lymphatic glands in the inguinal and femoral regions were very frequently enlarged, though examples of the spongy condition were rare—solid hypertrophy being the rule.

Hernia complicated the operation in instances. In one interesting case it was of the irreducible variety, and from it over a pound of omentum was removed. Several of the patients had also elephantiasis of the arms or legs, and some of both.

The following are the

ORDINARY FORMS OF THE DISEASE AS MET WITH.

(a) The hard and solid type of elephantiasis is shown in photo. No. 8.

(b) The mixed type—hard, but not solid, as it contained two hydroceles; is shown in photo. No. 11.

(c) Very large hydroceles with thickening of the lower part is shown in photo. No. 10.

(d) Elephantiasis affecting merely the coverings of the penis is shown in photo. No. 9. The scrotum was healthy in this.

THE GENERAL PREPARATION OF THE PATIENT FOR THE OPERATION.

From what has been noted about the great variety of patients coming for treatment, it will be understood that the preparation of the case is of the first importance, if a successful issue be ever regarded as the *sine quâ non*.

The routine pursued by me is that the individual first has a hot bath, and is provided with a comfortable bed with plenty of warm clothing. Especial attention is then directed to calming the mind of the restless, excited and nervous. Removal of causes of worry, fear or anxiety I reckon as of great use, hence such a patient is placed near or with others that have been operated on. This explains to such the unknown, and gains the confidence of the afflicted one. The appetite is studied, and food, as may be judicious, is given—the nurse being instructed to see how the food is eaten. Concurrently the microscopic investigation of the blood is being prosecuted for *filaria*, and the usual examination of the urine and stools is carried out. In the bloated and obese the abdominal plethora is combated; and in the emaciated and cachectic, anæmia, fever and spleen are corrected.

THE LOCAL PREPARATION.

A daily hot hip-bath, and a thorough inunction of the parts, which have been shaved, with a creamy lather of coal-tar soap, improves the nutrition of the tissues—œdema hardness and irritation of the skin adjacent subsiding.

When eczema or ringworm, which are common complications, are present, lin. iodi, or ichthyol, brings about a cure.

SPECIAL PREPARATION FOR THE OPERATION.

Having determined that the patient is in the best condition possible under the circumstances for the operation—

On the day previous

a purgative is given in the morning, followed by a good enema at night. The parts being re-shaven, are washed with 1—20 carbolic lotion and a lather of carbolic soap (20%); then rubbed with turpentine, and again washed with perchloride lotion (1—1500). Lastly, a dressing of perchloride gauze, wrung out of 1—20 carbolic lotion, being applied, is confined with a bandage.

On the Morning of the Operation

the parts are again washed, and the routine of the day previous repeated.

The patient is then carried in his bed to the operating room, due attention being paid to the avoidance of

chill. When he is placed on the operation-table he is clothed in a flannel shirt, with long stockings on his legs, and he lies on a thick blanket which extends from his sacrum to his neck.

Position of the Patient.

The patient occupies the lithotomy position at the end of the table. The assistants hold him in such a way that the thighs can be abducted or adducted; or the pelvis tilted up as required according to the various stages of the operation. (Assistant to right of patient grasps the inside of patient's knee with his left hand, and the dorsum of the foot with his right hand—the knee is well flexed and the foot well abducted. The assistant to the left of the patient grasps the knee with his right hand and the foot with his left hand.)

Intelligent assistants, holding a patient well, greatly facilitate the steps of the operation. With efficient aid there is thorough control, and it is possible to avoid every source of soiling or contamination of the field of operation—so essential if the wound is to run an aseptic course.

I consider this position is superior to having the patient supine on a table: it not being possible, in the latter, to be as sure of continued surgical cleanliness during the lengthy period of the operation, and, more especially, the satisfactory making of the flaps in the supine position is less easy.

It may seem absurd in my drawing so much attention to keeping the patient's back warm; but experience has taught me, in these days of glass operating tables and other fal-lals of surgical millinery, that the subject of the operation is frequently given credit for greater powers of endurance than the results sometimes justify. A temporary congestion of the viscera of a man, from lying with his back improperly protected on a cold table for an hour, will turn the scale against him should his life be in the balance from innate debility, operative shock, or other complication.

A percentage of the mortality in this surgical procedure, I am convinced, is due to some neglect of ordinary guiding principles.

THE OPERATION.

The Rubber Tourniquet.

In most of my cases I have used the rubber cord— $\frac{1}{4}$ " thickness—applied in the manner shown in photos. Nos. 1 and 2, which, better than letter-press, illustrate its application.

Latterly I have not employed any such appliance, but proceeded with the incisions, picking up the vessels before cutting or immediately afterwards.

The advantages of the rubber-cord are that—

1. When the operator meets with these cases at first, it gives him confidence to know that the circulation is under control.
2. Less blood is undoubtedly lost at the early part of the operation, so in cases where a few ounces of the fluid may be of vital importance, it is advisable to use the tourniquets.

Its disadvantages are that—

1. When the mass of the tumor, on the neck of which it rests, has been cut away, the cord may slip over the wound and introduce elements of septic danger.

2. If it can be done without, the operation is simplified.

3. Its removal subsequently requires care to prevent the ends touching the recent wound, and the operator soils his hands if he carries out the unwinding himself—an untrained assistant will probably make a muddle of the simple act! *Experientia credat.*

4. Of much more importance is the fact that the "weeping" from the large surface is less and the blood stasis more perfect if the cord be not used. The wound can be closed without delay, saving valuable time, so that the patient is got comparatively soon off the table into his bed.

Let the Surgeon, who has fingers and only one thumb on each hand, get rid of an inordinate fear of blood, operate quickly, *without hurry*, bear in mind where the vessels are to be found, and, with the exceptions noted, he will relegate the cord to the limbo of obscurity, to be used by those who still have, metaphorically speaking, to cut their surgical teeth.

The Assistants.

In addition to the two holding the patient, and one in charge of the irrigator, another, with clean hands, is all that is required. I prefer also he should bear in mind that "they also serve who only stand and wait." The operator must learn to carry out his work without assistants—having placed his instruments conveniently to his hand, he should do everything without dependence on those standing round, carrying on his duties "*cito, tuto, et jocunde.*" The fourth aide will hold the penis when told, or steady the mass of the tumor, or catch a forceps; but the only hands in the wound are the operator's.

Incisions.

The first I make is in the median line from near the pubis to the preputial mouth. This is deepened to the dorsum of the penis, and the finger is run up and down on either side of its body, very effectually enucleating the organ from the suspensory ligament to its free extremity, where the glans is still separated from the finger by the lining membrane of the prepuce. Pull the head of the penis up and out through this cap of mucous membrane in front of the glans which is palpable with ease through it. The organ is now free with its head covered, as it were, with a night-cap: slit this up, being careful to hold it away from the wound to avoid douching the old retained smegma preputii into the raw surface. Clean well, wrap round with a little gauze and leave for the present. Ordinary care up to now has prevented any injury to the dorsal vein, and there has not even been a chance of slitting up the penis, as some have done, in the old method of decorticating, on a long-handled director, pushed in by the preputial orifice, which, by mistake, has got into the urethra instead of arriving at the corona glandis.

Now pull the mass to patient's right (exposing the left side of the neck of the tumour). Cut from above

near external abdominal ring, carving towards the median line in front of the anus. This incision is on the neck of the tumour, at the scrotal angle, and will vary in position, inwards or outwards, according to the state of health of the skin—bearing in mind that this must ever be soft and pliable, that the subcutaneous fat on exposure must have the ordinary healthy yellow appearance, with no tendency to an œdematous or blubbery look. The trunks of the vessels will be found running obliquely inwards at the upper angle, transversely inwards at the middle part, and will have an antero-posterior direction behind. They can be seized before section, or after cutting, with pressure forceps.

Deepen this incision gradually and work in with finger and scalpel to near the bulb, avoiding any hurt to it.

Repeat the same procedure on the right side of the neck of the tumor. The two incisions will have met in front of the anus, and all the main vessels will have been seized and divided, and the bulb almost cleared on either side.

The next step is the *enucleation of the testicles*. Unite the base of the median incision with the upper end of the lateral cuts on either side, seizing the vessels as previously described. From the centre of, say, the left of these, over the line of the cord, the knife is freely used—making a vertical wound through the substance of the growth, which is deepened till the cord be exposed, then the finger, being inserted, is worked around the cord, and moved up and down, enucleating it and the testicle completely, save at the lowermost end of the gland, where is its firmest attachment, which is the remains of the central part of the gubernaculum testis. This must be cut away with a blunt-pointed scissors, and every trace of blubbery material should be carefully removed at the same time from off the outer surface of the tunica vaginalis.

Repeat over the right cord and testicle the process described.

The firm testicular attachments are shown in photo. 4, which illustrates the condition of the field of operation at this stage of the procedure, but before final separation of the testicles. Should a hydrocele be present, it is removed unopened, it being much easier to dissect out the distended tunica vaginalis than after the escape of the fluid. Then open the hydrocele in front (be careful here, as the testicle is often distorted and transposed). Cut away the tunica vaginalis laterally on either side to near the mesorchium—being specially on your guard above and behind the globus major of the epididymis.

Wrap the testicles and cords in guaze, and place them on the pubes.

Torsion Clamp Method of Blood Skins.

Now twist, to say four turns, each vessel held by a pressure forceps, and, before removing it, with a second forceps, clamp the twisted artery. The clamp action of the second keeps up the twist, and it can be taken off in a few moments. I have absolutely ceased the use of the ligature (save the exceptions noted further on) since taking to this torsion-clamp method. I consider, and experience

has proved to me, that with it the ligature is unnecessary. In such an operation as this, where as many as 40 vessels at times require attention, if two score pieces of outgut can be done without, the success of the procedure will not be endangered by structures, some of which might subsequently play the parts of "foreign bodies" in the economy of the healing process. The above method is used then throughout the whole procedure.

The appearance of the field of operation on the complete removal of the tumor is shown in photo. 5. The large extent of the wound is to be noted, in which the decorticated penis is held aloft with a forceps, and the testes hang low, suspended by the lax cords. The wound is dry—there is no weeping, and no sutures have been used. In fact, instead of the worrying ooze, ooze, that follows the use of the rubber cord, there is the glaze of the healthy plasma.

THE FLAPS.

Now the skin to the right of the wound is to be drawn forwards. Its inner side is lined by the fascia of COLLES, and it is the deep surface of this structure that is exposed. Pulling the skin and fascia taut, with a scalpel, make an incision through the latter $\frac{1}{2}$ " long. Put aside the knife, and entering the finger by this window, move it up and down and out, freeing the skin from its attachments to the fascia lata over the origins of the gracilis and adductor muscles.

The vessels will feel as small fibrous cords passing from the deep parts to the overhanging integument like a series of pillars from a floor to a ceiling. They are not broken by the finger working its dissection through the superficial fascia, although the blood stream in them may be interrupted for a time by their somewhat rough usage—it must be quickly re-established, as I have not yet met with a single case of gangrene of the flaps.

Practice will determine the amount of covering necessary, but the free margin should come to the median line without tension. Snip with blunt-pointed scissors any portion of COLLES's fascia obstructing the sliding in of the flap. Proceed on patient's left side with the same method.

Having done so, take the right testicle. See that there be no oozing from where the tunica vaginalis has been cut away, nor bleeding from any portion of the cord from an injured vein. These are the only parts in the whole operation where a ligature may be found necessary. Place the testicle under the skin flap on the thigh. Repeat the same with the left testicle, and draw the flaps to the median line. A few temporary stitches of silk-worm gut keeps them in position, whilst a continuous suture, run quickly up, holds them firmly.

Horse-hair Drains.

Before the suturing is completed in front and behind, a dressing forceps is passed in from below, and its jaws appear at the base of the penis in front. The ends of two drains being seized, they can be drawn down to the lowest extremity of the wound—a little manipulation making their upper ends fall in and lie on either side of the base of the penis under the pubic flaps.

The wound in front of the penis is closed in a similar way to that behind. During these stages the assistants, holding the thighs, lower them, or approximate them, as required—thus relieving any tension.

There now remains but the very important work of

Stitching the Flaps to the Body of the Penis.

Six sutures of horse-hair, with a fine needle, should be introduced at equi-distant points through the tunica albuginea and the flaps. It is quite unsatisfactory to merely stitch the skin to such cellular tissue as may remain on the body of the penis. Finally, avoid piercing the dorsal vessels, and merely take up the tunica, and not the erectile structure, and you will introduce no complication into what will give a good result.

The mobility of the skin thus treated is very considerable—so much so, that it is possible in every case to bring it over the immense wounds which at first look so hopeless (see photos. 5 and 6), and provide not only a covering of sound and healthy integument to the perineum, but also to obtain immediate union as well (see photo. 8). Should any small portion of the lining of the prepuce have been left, being healthy, let it be stitched to the tunica albuginea. If there be the least sign of degeneration, the whole of it should be pared close to the cervix. It is in the first class of case that great care is to be paid to the application of the penile bandage, which should grasp firmly and evenly the corona and the tissues behind it, slacking off near the pubes. The little flap will then take root and not become oedematous. The only uncovered part remaining will be the circumference of the penis between the basal and cervical flaps (see photo. 6). This about the fifth or eighth day is grafted by THIESSEN'S method.

The chief points about the Flaps are as follow :—

1. They are derived from the integument of the upper and inner part of the thighs over the adductor and gracilis muscles.
2. The only time the knife is used is when the little window is cut in the fascia of COLLES.
3. The finger does all the other separation necessary.
4. The vessels are not necessarily broken.
5. The skin is shifted in by gliding.
6. For a good result, asepsis is absolutely necessary.

The Dangers connected with the making of Flaps are—

1. Should the wound not remain aseptic, the operator has opened up an enormous area of very absorbent tissue.
2. If the knife be used too freely, the vitality of the integument might be affected, and there would be danger of sloughing.

Photo. 6 represents the wound shown in No. 5, now closed in the median line—the flaps joining on the pubes, in front of the penis, and falling on its sides, where, being drawn forwards on it, they are sutured firmly to its fibrous envelope embracing its circumference like a ferule, and thus absolutely preventing the possibility of two granulating surfaces—common in the old operations—uniting and binding it by cicatricial tissue to the perineum, rendering it useless as to intromittent powers,

and, when used as a micturating organ, strongly reminding one of the function as performed in the *osmelidæ*. Photo. 12 shows this. It is from an old case of recurrence. The patient urinated backwards—coition was, I think, a gymnastic feat.

In photo. 13 the organ is situated in the midst of firm cicatricial tissue. To both of these individuals, natural urinary and genital functions were restored by me.

Behind the penis, in the mid line, there are seen the sutures ending posteriorly at the gap left for the extremities of the two horse-hair drains. On either side of the line, the bulgings corresponding to the testicle, are manifest.

Condition of Testes.

I know of no better opportunity for studying the external anatomy of the testicle than that afforded in the operation for elephantiasis scroti. One cannot imagine beforehand the marvellous changes in shape that the pressure of this disease causes.

If the testicle be quite flattened out, represented merely by a mass of fibrous tissue containing a little gland material, supported by a lengthy flabby cord, the circulation in which is dull, I think the best practice is to remove it—more especially if masses of leathery tunica have had previously to be cut away. Should an abscess have been present in the tunica or testicle, certainly castrate.

I have noted in all cases of hydrocele either congestion of the head of the epididymis, where the tunica is reflected from it backwards to the mesorchium, or fibrous induration of the same parts. It is possible that disease in the veins or lymphatics, at this situation—"filtration-angle," as it were—may have to do with predisposing to hydrocele.

THE SOURCES OF HÆMORRHAGE DURING THE OPERATION.

The vessels of macroscopic anatomy are greatly enlarged, and their branches increased in number and in calibre.

1. At the root of the penis, and over the cord, at the superior external angle—superior external pudic Vs.
2. At the outer side of the cord—inferior external pudic Vs.
3. Passing in to the side of the perineum—muscular branches of the sciatic.
4. Running from behind forwards to the back of the tumour—superficial perineal Vs. (always the largest).
5. When lifting out the cord and reflecting its coverings if diseased—cremasteric Vs.
6. The dorsal vein of the penis should never be injured. At times it is very large, but it is not necessary to interfere with it.
7. The frænum—its artery. The most troublesome vessel in this region! Frequently it will not be denied a ligature!

The foregoing are the trunks that furnish blood to the tumour superficially, and if the incisions be planned, as I have directed, the supply is stopped off at once; whereas, if the testicles be enucleated, first an extra quantity of

blood will be lost, as the vessels, now cut at their distribution, have again to be divided at the neck of the tumour!

Therefore, in operating without the Cord—

1. Note first the lines of approach of the vessels.
2. Make the incisions in the order stated, seizing the arteries as soon as divided, or on exposure.
3. Employ no ligatures—use the torsion-clamp method.

The Sutures.

Silkworm gut for main supporting stitches on the pubis and in the perineum, and strong horse-hair as a continuous suture, or not, as may be desirable. Fine needles and fine horse-hair are requisite for stitching the flaps to the tunica albuginea of the penis.

Drainage.

I employ two horse-hair drains placed as noted above. Rubber-tubing is not necessary.

The Dressings.

A strip of sterilised oiled silk may be placed over the line of the wound and another around the denuded penis. The former is not required, and may be dispensed with, as there is no granulating surface where it is applied—the union being by *first intention*. The penis, on the contrary, is decorticated, and the silk will facilitate the subsequent removal of the dressings.

Strips of sterilised boric lint wrung out of 1—2% carbolic lotion are then applied over the perineum and around the root of the penis.

Penis Dressing.

The penis being grasped by the finger tips of the *aide* applied to the glans, is well drawn out, and a bandage of gauze (perchloride or iodoform), 1" wide, is wound carefully around, fairly firmly near the cervix, less so towards the root. If this be not attended to, the end of the penis will swell, and should any healthy mucous membrane have been left from the interior of the prepuce, as a flap, it will become oedematous. Again, if loosely applied, it will gape, and the wound on the penis will become septic.

Perineal and Pubic Dressings.

The gauze (perchloride or iodoform) in proper lengths of single filmy thickness is applied by allowing it to fall and arrange itself in folds from above down. The inner parts cling alongside of the penis, enveloping its base laterally, and also its dorsum and venter to its middle. The gauze, falling thus, adapts itself well, and should form an even pad, extending back to the anus, and forwards above the pubes to near the umbilicus, and well out beyond the pubic arch on to the thighs.

When so used, it gives a resilient dressing, and forms a sort of valve around the base of the penis, to the bandage on which it must be evenly and firmly stitched.

The old-fashioned way of taking many folds of dressing and cutting a hole in the centre, and then bringing the penis through the opening, is wrong, as by it one

will find it practically impossible to maintain the wound sweet. The portion of the wound most likely to get septic is that at the base of the penis—first, because it never gets rest owing to changes in the size of the penis; and second, if the dressings be not brought up and stitched to the sides of the penis bandage, there will be an open space due to loosening of the dressings in a few hours as the patient shifts about in bed. The method recommended gives an elastic pressure, perfect and even closure of the field of operation in this dangerous region, and, since using it first, continuous experience has further impressed upon me its importance and the futility of the old way.

Dr. MANSON says (p. 527, *Tropical Diseases, 1900*): "The dressing should be massive, well padded, and kept in place by an eight-tailed bandage secured in front and behind to a strap round the waist, a hole being cut in front for the penis to emerge. The large wound generally does well."

However applicable this may be for the operation recommended by Dr. MANSON, it is quite unsuitable for my method. The dressings must be well and equally applied, as described, and kept firmly in contact by a roller affording even pressure as shown in photo. 7. The manner in which this is done is of importance. Should the application of the bandage be slovenly or careless, the dressings shift, the margins gape, the flaps are not maintained by an uniform pressure, and sepsis is the result!

If my method be pursued, other things being equal, the large wound (covered in now) will not generally, but ALWAYS do well!

THE BANDAGE.

Very important, indeed, is the correct binding of the bandage, and it well merits its personal application by the surgeon. The material is what is known in the bazaars here as "bandage-cloth." It is manufactured in the villages, and costs there about 4 annas a *thad*, and 7 annas in Calcutta. English bandages of calico are quite unsuitable. Photo. 7 represents the patient resting on the bandaging-block that I use, and it will be found a most convenient one for the purpose.

It also shows how the roller grasps firmly the pelvis and compresses the dressings on the pubes; and, in the manner of a double spica, holds firmly the tissues at the upper and inner parts of the thighs—disturbed by the shifting in of the skin for the flaps, and how it crosses and re-crosses the perineum, from before backwards and from behind forwards, supporting evenly and well the flaps covering the testes and root of penis. Its continuity with the penis bandage is also manifest. In fact, the pelvis and pubis, the groins, perineum, and inner parts of the buttocks, are so bound that the gauze is thoroughly kept in position, and yet the anus is uncovered and no obstruction is there to the passage of a soft catheter if required. Safety-pins and a needle and thread judiciously used, especially in the dangerous area, make everything absolutely firm, and prevent exudation and give that rest so essential for the quick healing of such an immense wound.

The bandaging having been completed, and the patient placed in a warm bed, a half hoop of bamboo supports the weight of the blankets, etc., from off the middle of the body. (In private cases I prefer the sheets of the bed to have been dried after soaking in boric lotion.) The knees being tied together, the patient may flex the hips or not, as he wishes, and he may be subsequently turned on either side, should he so desire. This facilitates the escape of flatus and relieves him from feelings of irksomeness.

SYMPTOMS OF SHOCK.

Should these supervene, then ether and strychnia hypodermically, and, if required, subcutaneous transfusion of saline fluid. I would caution the operator to be especially on his guard in cases where there is also elephantiasis of the legs or the arms. Also the chloroformist should bear this same caution in mind. Bandaging the extremities, and their elevation, together with the application of the faradic current, superadded to the foregoing measures, will rescue what otherwise might prove a hopeless case.

SUBSEQUENT TREATMENT.

The bladder may require to be relieved, and for this the instrument of choice is a good No. 8 JACQUES red rubber catheter.

On the fifth day the bowels are moved by a laxative, or enema, or both, and then

THE FIRST DRESSING

is carried out. The position most convenient for this is that shown in photo. 8, where the patient is supported comfortably on a dressing-block, which is a padded oblong piece of wood 5" square on section. (The bandaging block previously spoken of is not suitable.) Over it falls a waterproof sheet, which covers the bed, and on this, underneath the pelvis, is a basin which receives the douching lotion. When the bandages are cut, the dressings easily come off as far as the boric lint. It also, on softening with lotion, gives no trouble. Thorough moistening of the penis bandage allows of its removal. The appearance presented is that of an aseptic united wound, such as is shown in photo. No. 8.

The whole field of the operation is then carefully washed and cleaned around. This is grateful to the patient, the gentle rubbing has also a healthy action on the circulation of the parts. The drains should have been removed early and found quite sweet.

If there be any irritation of the tissues from the antiseptics, I use sterilised boric gauze next the skin and apply it dry.

The re-dressing is carried out as at the operation, and the same care is taken in the application of the roller (the bandaging-block is now substituted for the dressing-block).

The bowels move daily, and the progress is generally uneventful till the

SECOND DRESSING,

which takes place on the tenth day, and is carried out in a similar method to that just described. Now the stitches may in part be removed, and the deorificated penis grafted after the method of THIERSCH, if this was not done at the time of the first dressing. The grafts are taken from the thigh or arm.

About the fifteenth day the patient walks about; but I do not allow him to sit. By the twenty-first day he can do as he wishes, and is ready for discharge.

THE CONDITIONS COMPLICATING THE OPERATION

are various. Those mentioned are such as I have met with—

(a) *Hernia*—*Enterocoele*—*epiplocele*—*entero-epiplocele*.

The radical cure can be performed at time of removal of tumour.

(b) *Hydrocele*—of the funicular, virile and testicular varieties.

Excellent opportunities for the study of the formation of these in all stages are afforded. The tunica vaginalis will be found in all states, from the thin, almost normal, membrane, to a structure $\frac{1}{2}$ " thick, studded with fibrous plates, which have the macroscopic characters of cartilage. This tunica is at times very voluminous, when great care must be taken in dissecting the upper portion from the structures of the cord, lest injury be done to the circulation of the testes.

(c) *Varicocele*—This is not so common as one would expect, though I have removed very large examples of it.

(d) *Great Length of the Spermatic Cord*.—In such a case, as is shown in photo. 10, this may be expected. Then the cord should be packed in half folds, and these stitched to each other and to the deep tissues above and below.

(e) *Blubbery Infiltration*.—Occasionally I have met with this surrounding the testicles and extending up the cords to the abdominal rings. As it is in the deep tissues, it is, of course, quite distinct from that met with in the usual site of the superficial fascia. Every trace of it should be cleared away.

COMPLICATIONS MET WITH IN THE AFTER-TREATMENT.

The commonest is an attack of fever, of a malarial character, with a temperature running possibly to 104°. This is speedily got in check by the use of ordinary diaphoretics, followed by quinine.

A condition causing more anxiety is where the patient gets fever of a continued type with daily exacerbations. The diagnosis here must be made as to whether the cause is septic poisoning, or is a fever with a malarial basis.

If of the latter character, the wound will be aseptic and uninfamed, no puffiness or pain will be present in the perineum, or in the pubic region. The countenance of the patient will not be anxious, his eyes will be clear, and his tongue clean, and when the fever is low, he will have a sense of well-being and express himself as being fairly comfortable; whereas if sepsis be the cause, the condition will be very different, and suppuration will be found in the wound or its neighbourhood. I treat this ordinary continued type of fever by giving freely tincture and decoction of bark with sweet spirits of nitre and acetate of ammonia. This mixture agrees much better than quinine, and seems to me much more efficacious.

If irritation of the skin of the pubis, buttock or flaps in the perineum of an eczematous nature occurs, due to the antiseptics, I recommend that dry boric gauze be used. The injudicious application of strong carbolic and perchloride lotions is to be deprecated. I have seen maceration of the cuticle, due to the abuse of these good agents. Iodoform drenched over the parts under the dressings facilitates the undesirable state of affairs. Given a clean wound, brought together without tension, cover it with sterile boric lint, and outside it apply the gauze charged with carbolic acid, perchloride of mercury or iodoform—the result will be as you desire.

Retention of Urine

is very common, and it is not to be wondered at. I can only say—do NOT use either a silver instrument or a gum-elastic catheter; but take a sterile JACQUES red rubber No. 9, and you will have no trouble, and the patient no pain, and a possible urethritis will have been prevented.

Troublesome erections

occur at times. An ice-bag to the perineum (oiled silk intervening between it and the dressings) is the most efficacious remedy. Of the virtues of camphor and potash bromide, I am sceptical. They may be tried.

ELEPHANTIASIS IN THE FEMALE.

Thorough attention must here be paid to the cleanliness of the vulva and vagina. The same routine as in the male, making allowance for the sex, is pursued, and the patient is prepared in like manner. As photos. 14, 15, 16 and 17 show, the disease may attack one of the labia majora, one of the labia minora, the prepuce clitoridis, this same structure as well as one of the nymphæ. In addition the whole external genitals may be attacked. In the cases photographed, the disease was limited as stated.

THE OPERATION

is very simple. An external incision is made through the healthy skin, and, inside the growth, a second one through the healthy mucous membrane. These cuts are deepened and prolonged forwards and backwards till they meet. The vessels are seized and the tumor removed.

I advise that a JACQUES catheter (No. 10) be introduced into the bladder before the incisions be begun, and be retained there. If this be not done, then the wound may be drenched with urine at an inopportune moment. It is also much easier to introduce the instrument before cutting the parts, as the subsequent retraction alters considerably the normal relations, which had already been rendered quite sufficiently bewildering by the nodular masses of the growth.

Blood stasis being perfect, the skin can be shifted in and united to the line of section of the mucous membrane of the vagina, which also is itself loosened and drawn down. No drain is required. Dry dressings are used and the vagina lightly packed with gauze.

The bandage firmly fixes the dressings in the manner described before, and the catheter has a stitch in it, fixing it to the roller as it passes through.

In five days change the dressings, and you will find the parts united, save superficially here and there. Simple applications and ordinary cleanliness now suffice.

CONCLUSION.

Finally, as to this operation, I may repeat now with greater emphasis what I said in 1897^c and ask that my procedure be judged in the usual manner—

1st.—as to the mortality attending it;

2nd.—as to the

(a) immediate, and

(b) remote results to the patient;

3rd.—as to the advantages it presents to the surgeon and the hospital.

1st.—Dr. HIRA LAL BASU, one of my assistants, has collected the statistics of the cases treated in the Civil Hospitals in Bengal Proper from 1882 to 1899. I give it below—as well as one showing the cases treated in the Medical Institutions in Calcutta from 1888 to 1899:—

Statement showing the number of cases treated in the Civil Hospitals in Bengal Proper between 1882 and 1899.

Total treated.	Cured.	Died.	Rate per cent. of death.
910	839	71	7.802

Statement showing the number of cases treated in the Medical Institutions in Calcutta between 1888 and 1899.

Total treated.	Cured.	Died.	Rate per cent. of death.
946	880	66	6.976

* Vide Indian Medical Record of 1st March 1897.

In the mofussil the mortality from the operation is, according to this statement, 7.802 per cent. In Calcutta it is 6.976 per cent. This is a great improvement on the old days, when the mortality was 18.2 per cent.

The tables drawn up by my House Surgeon Dr. DEBENDRA NATH HAZRA, assisted by medical student SUDHAKER MAHAR, and examined for me by Dr. SATYA SARAN CHAKRAVARTI, the Registrar of the Medical College Hospital, show 140 cases of this operation successfully done by me. These cases are consecutive operations, and not selected, and a perusal of the matter under the heading

CHARACTER AND CONDITION OF THE PATIENTS,

will show that the patients were not all favorable cases for a surgical procedure of magnitude.

2nd.—(a) The patient has a wound covered with skin, and is therefore less liable to septic absorption and its concomitant evils. The perineum is closed and healed up in eight days. The flaps are continuous on and around the base of the penis, hence there is no necessity for clearing the penis from off underlying granulations, since none exist. The organ is quite free. Compare this with the result from the old operation.

In photos. 12 and 13 I am enabled to show the condition that usually followed that procedure—as far as binding down of the penis to the granulating surface that surrounded its base. The cicatricial bands are well shown. It can be imagined that copulation was impossible, and in No. 12 urination was *à posteriori*. I successfully operated on both these cases and restored the function of the organs with the removal of the growths. The flap method then precludes such untoward results.

(b) The remote effects are very favorable—being a pliant and soft perineum, and a penis covered with skin instead of cicatricial tissue, thus giving an organ in every way fit for its duties. I have seen many of my old cases and found everything very satisfactory as to these points.

3rd.—The surgeon has several advantages—(a) He cures his patient quickly—average under 30 days. (McLeod's published cases, operated on by his method, give an average of 70 days in hospital.) This advantage leads to less crowding and more beds.

(b) There is no fouling of the air of hospital wards by having numbers of cases with pus-forming sores occupying them.

(c) The wounds being closed and healed in eight days, the responsibility for the case is less, as any possible negligence of a dresser could then inflict practically no damage after that period.

McLEOD (*Heath's System of Surgery*, Vol. II, page 399,) propounds two questions demanding consideration in elephantiasis scroti:—

(1) "In what circumstances is recourse to operation justifiable or desirable?" and (2) "what is the most approved and successful method of operating?"

With reference to the first proposition, I may state that in this series of 140 consecutive cases, I have operated on every patient that presented, preparing each, however, for the operation according to the recognised cardinal rules of surgery. As I have before stated, the series embraces examples of all the ordinary complications usually found, and the exception was to have a wholly uncomplicated case.

Regarding proposition 2, I can at least claim that the method brought forward can be done well and with simplicity, and that the immediate and remote results are more favourable than in any other way of operating in elephantiasis of the genitals.

No.	NAME, AGE, CASTE, OCCUPATION.	Same disease in family.	Other cases in his village.	Hydrocele.	Syphilis.	Previous History. Fever and Inflammation.	Skin-disease.
58	Behariall, Hindu, rent collector, age 40.	None.	Rare.	None.	None.	Periodical fever with inflammation of inguinal glands at intervals of 25 to 30 days.	Eczema.
59	Dhani, Hindu, cultivator, age 30.	do.	Rare in his village, but common in Moorshidabad, where he used to reside for the past several years.	Yes.	do.	Periodical fever at full and new moon with swelling of inguinal glands, and scrotum afterwards.	Ringworm long ago when a boy.
60	Sheik Badal, Mohamedan, farmer in a jute-mill, age 30.	do.	Rare in his village.	do.	Yes. He had, it about four years ago.	Periodical fever at new and full moon with swelling of inguinal glands, and red pimples used to appear on the scrotum.	Ringworm.
61	Sukhadi Ram, Hindu, duffry, age 24.	do.	None.	do.	Yes.	Periodical fever at full and new moon with slight inflammatory condition of the spermatic cord.	None.
62	Kandarpa, Hindu, male, farmer, age 50.	do.	Frequently met with in the locality.	do.	do.	Periodical fever every 15 days, lasting for a day or two, with orchitis of the left chord.	Eczema.
63	S. C. Bonard, E. I., male, compounder, age 30.	do.	Rare in his village.	do.	do.	Gets malarial, but not inflammatory, fever.	Had eruption of S. S., but no other skin disease.
64	Benode, Hindu, male, shop keeper, age 40.	do.	do.	do.	None.	Periodical fever at full and new moon with swelling of the scrotum and testes.	None.
65	Luchman, Hindu, male, coolie, age 40.	do.	do.	do.	Yes.	Periodical fever at intervals of four or five months with swelling of scrotum	Ringworm.
66	Parbat, Hindu, male, cultivator, age 35.	do.	Saw two cases in his village.	None.	Yes. Chancre.	Periodical fever at intervals of a month, and sometimes at intervals of a week with swelling of the scrotum.	do.
67	Ramsatya Gerait, Hindu, farmer, age 35.	do.	None.	Yes.	None.	Had twice fever with inflammation of inguinal glands.	do.
68	Amulyanath Chatterjee, Hindu male, Brahmin priest, age 23.	His father had hydrocele.	Frequent.	do.	No.	Getting intermittent attacks of fever for the last three months, with pain in the joints.	Eczema.
69	Behariall, Hindu, male, grocer, age 46.	His father had big, scrotal tumour of similar size.	Some other cases present in his neighbourhood.	do.	Yes. Soft sore.	Getting fever for the last six months.	Ringworm.
70	Saroda Prasad, Hindu, male, cultivator, age 40.	Nil.	Frequent.	do.	No.	Fever during new and full moon.	Scabies all over the body.
71	Kunjabehary Chuckerberti, Hindu, Brahmin priest, inhabitant of Bankura, age 52.	His father had hydrocele.	do.	Had hydrocele.	Yes.	No fever; had two abscesses in the scrotum.	No.

* The table of cases from 1 to 57 appears with Professor Charles' valuable article in the *Indian Medical Record* of 1st March 1897.

Duration.	Where begun	Condition of inguinal gland.	Character of tumour.	Date of operation.	Date of discharge.	Days in hospital after operation.	Weight of tumour.	Microscopic examination of blood.	REMARKS.
4 years.	On scrotum.	Slightly enlarged.	Elephantoid.	15-4-98	2-6-98	1 month and 17 days.	1½ lb.	Not examined.	Suffered from malarial fever after operation.
10 years.	do.	Slightly enlarged and indurated, especially obliquely ext.	Elephantoid with hydrocele complicated with urinary fistula.	14-5-98	24-6-98	1 month and 10 days.	7 lbs., besides hydrocele fluid 24 oz. from both sides.	do.	Practically healed up in 15 days. Subsequent skin-grafting.
More than a year.	do.	Not enlarged.	Elephantoid.	30-7-98	21-8-98	22 days.	2 lbs.	do.	Uninterrupted recovery.
4 years.	do.	do.	Sarcocele double.	4-8-98	22-8-98	18 days.	1 lbs.	do.	do.
8 years.	do.	Slightly enlarged and indurated on left side.	Elephantoid with hydrocele and hernia.	10-9-98	17-10-98	1 month and 5 days.	6 lbs.	do.	Suffered from malarial fever.
Nearly 6 months.	In prepuce.	Not enlarged.	Elephantoid with hydrocele.	21-9-98	5-11-98	1 month and 14 days.	1 lb.	Filarie present.	do.
6 years.	On scrotum.	do.	do.	28-9-98	25-10-98	27 days.	2 lbs.	Not examined.	Nothing important; skin-grafting.
7 years.	do.	Enlarged.	do.	10-10-98	22-12-98	2 months and 13 days.	11 lbs.	do.	do.
or 4 years.	do.	Slightly enlarged.	Elephantoid.	5-11-98	9-12-98	1 month and 4 days.	8 lbs.	do.	do.
3 years.	do.	Slightly enlarged, but moveable and distinct	Elephantoid with hydrocele.	13-2-99	23-3-99	38 days.	6 lbs. 8 oz., besides fluid 3 oz.	do.	do.
3 years.	do.	Indurated on both sides.	Elephantoid.	29-10-98	2-12-98	1 month and 13 days.	3 lbs.	do.	do.
4 years.	do.	Not indurated.	do.	3-12-98	25-1-99	1 month and 22 days.	Solid portion 37 lbs. Liquid 13 lbs. aspiration.	Filarie present.	do.
5 years.	do.	A little indurated on both sides.	do.	26-11-98	1-1-99	1 month and 22 days.	2 lbs.	Not examined.	do.
2 years.	do.	Shotty and indurated.	do.	10-12-98	22-1-99	1 month and 12 days.	15 lbs.	Filarie not found.	do.

Indian Medical Record.

6th March 1901.

PREVENTION OF MALARIAL FEVER.

As the result of the labours of the Committee of the Royal Society in Western Africa, some very interesting and very practical observations have been published regarding the prevention of malaria, which, we may add, is now almost universally accepted as being a disease spread by the agency of certain species of the anopheles mosquito.

Regarding the immunity ascribed to the natives by many of the older observers, we now are given a commonsense explanation. The immunity, such as it is, is an acquired immunity, the resultant of many previous attacks of the disease.

In children there is no immunity, and the immunity of adults even is not absolute; they sometimes get the disease in its worst form. They are therefore situated with respect to malarial fever much as adult Europeans are to measles or scarlatina. Most of them do not get the disease, because they have had it when young; but those who have not previously suffered may get very severe attacks.

The proportion of native babies and children under two years of age, who are infected with the malarial parasite, is very large.

The common belief that natives suffer less from mosquitoes than Europeans appears to be untrue. Europeans may feel more irritation, but natives are more attractive to the insects, and are bitten to a greater extent. In proof of this, it is stated that anopheles frequently swarmed in the native houses, while in those of Europeans, a short distance away, very few or none could be found.

The following experiment affords still further evidence of the same thing:—

"In a tent in which a European had been accustomed to sleep, pitched in the compound at A., only one or two anopheles were usually to be found in the morning. Two natives were then allowed to sleep in the tent, with the result that the first morning 19 anopheles were captured. The second morning 62 anopheles, most of which had fed, were caught. The natives did not complain unduly of mosquitoes. The use of the tent by the natives was then discontinued, and the anopheles rapidly became fewer in number."

Some interesting information is given about the habits of the anopheles, its breeding places, and the manner of the preservation of the species.

The larvæ require still water to thrive in, as they are surface feeders; therefore large bodies of water or large tanks are not suited for them.

If dried for 48 hours, the eggs will not hatch; earth taken from dried up pools in which larvæ had been,

and placed in conditions suitable for hatching, did not produce any larvæ. The eggs, therefore, do not lie dormant in the soil during the dry season, and then turn into larvæ with the first rains, as has generally been supposed.

The larvæ of anopheles were found in brooks, both in town and country, in small tunnels of water, in pools left among the rock beds of streams, otherwise dried up in the dry season, in natural more or less permanent pools, in the water which collects in pits dug by the natives to get the mud used in building their houses, and in temporary pools during the rains, which persist for a fortnight or more.

They were also found in some wells, and in great abundance in pools and ponds in low-lying places where the ground water is very close to the surface. The breeding places are more numerous where the ground water is sufficiently near the surface to be reached by pits or other excavations dug for the purpose of building houses or for any other purpose. They were also found in brackish water and in water containing 0.6 per cent. of salt.

BEHAVIOUR OF THE SPECIES.

From observations made, it is believed that the adult anopheles can exist throughout the whole of the dry season concealed in grass, shrubs or trees, waiting until the first rain falls to lay their eggs. At Sierra Leone, in a particular area that had been free from breeding grounds for three months, anopheles were still to be found ready to lay their eggs.

Experimental pools formed in the dry weather and supplied with pure water soon became infected with anopheles larvæ, which must have been hatched from eggs recently laid.

Granted, then, that the adult anopheles can live throughout the whole of the dry season, it is important to learn that its most favourite haunt is the dwelling-houses of the natives. In Lagos, at the end of the dry season, anopheles can be found in nearly every native hut; they pass through much or the whole of the dry season without breeding.

A certain proportion of the anopheles found in the native huts were always infected.

Thus in Africa, at any rate, the native is the great benefactor of the anopheles or malaria mosquito; he provides him with food and shelter, and only too frequently he kindly constructs ponds for him to breed in. The anopheles is a parasite, living with man and on man, and sharing with him the honor of providing in its body a suitable medium for the growth and development of the microscopic organism which causes malarial fever. This is the marvellous conclusion to which the most recent scientific researches into the origin and cause of malarial fever has led us. Let others bring these observations into harmony with the grand scheme of creation, where everything is subservient to man—it is our part to deal merely with the facts.

The protection of the native in Africa is considered to be hopeless at present, and the protection of the European depends upon his isolation from the native.

The following is the conclusion of CHRISTOPHER and STEPHENS :—

"So closely associated, indeed, are malaria and the native in Africa, and so wonderfully constant is the presence of anopheles where natives are collected in numbers, that we doubt whether any operations, now possible, directed against anopheles, will do much to diminish the danger of malarial infection. In fact, in Africa, the primary aim should not be the destruction of anopheles, but rather to remove susceptible Europeans from the midst of malaria. To stamp out native malaria is at present chimerical, and every effort should rather be turned to the protection of Europeans."

It is important in this connection to learn that the anopheles can fly greater distances than is usually imagined. CHRISTOPHER and STEPHENS put it at 400 to 600 yards.

Personal protection from malaria is now nothing more or less than protection from the bites of anopheles mosquitoes, and the sooner every one learns to recognise this variety of mosquito, the better.

The protection of a community is, however, a different thing, and depends, as we have seen, on the separation of Europeans and natives.

The conditions to be fulfilled in camps are thus stated :—

1. A site should be selected for European dwellings as far as possible from a native village; a mile would undoubtedly suffice.

2. The camp of the native labourers should also be placed at the greatest possible distance (half a mile to a mile).

3. The house servants and others should not sleep in the European compound, but a quarter to half a mile away.

4. One personal servant only should be allowed to remain in the camp at night.

Native children are the great source of malaria; their blood is almost invariably infected. Natives over ten years of age are more or less immune. It is most important to note that the native child may present none of the usual characteristics of an attack of fever, though all the time its blood is full of parasites.

In Europeans we are told that parasites are rarely found, except in definite attacks of fever.

The grand conclusion is that malarial fever is a contagious disease contracted through the medium of the mosquito and the native child.

All the foregoing practical details have no doubt an equally important relation to the country, and now that the way has been pointed out, observations will gradually accumulate to show their truth.

One conclusion that we think may be safely drawn from them is that KOCH's prophylactic method is not likely to be of any advantage in a country of mixed population.

His method is to dose all the people with quinine in the season when the mosquitoes are dormant, so that there will be no infected blood to infect the succeeding broods

of young anopheles, and of course the young anopheles are harmless, unless they have fed on the blood of a person suffering from malaria.

The fact that young children and infants are the chief sources from which the anopheles get the infection is sufficient to show the futility of KOCH's proposition.

A REVIEW OF OUR KNOWLEDGE OF MALARIA.

THE *New York Medical Journal* publishes in detail an address delivered at the opening of the Twentieth Annual Session of the Philadelphia College by Dr JOSEPH MCFARLAND, M.D., Professor of Pathology and Bacteriology, on the progress of medical knowledge in reference to malaria. We cull the essentials. The speaker pointed out that the accumulated knowledge of malaria in 1880 was as follows: (1) The disease is not universally prevalent, but is confined to well-defined and usually rather circumscribed districts, in some of which it is continuously prevalent and extremely pernicious; in others intermittently prevalent and milder in type. (2) The districts in which the disease prevails are usually marshy lowlands. (3) The disease is most prevalent and severe in the summer, especially in damp seasons and toward the autumn. (4) The danger of infection is greatest after sunset and during the night. (5) All ages, both sexes, rich and poor, black and white, may become affected, though the Negro resists the disease better than the white man. (6) Newcomers in a malarious district are more liable to infection than the regular inhabitants. (7) The infection occurs most readily near the ground, and by living in tall buildings, ascending to neighbouring hills at night, may be avoided. (8) The danger of infection is greater in still than windy atmospheres. (9) The danger of infection is increased by sleeping with the windows open at night, especially on the side of the house toward the marsh. (10) Trees planted between a domicile and a swamp seem to keep off the infection. (11) Winds carry the infection but a short distance. (12) Thin clothing predisposes to the disease if worn at night. (13) The disease is not contagious.

Three important discoveries had been made since 1880: (1) The discovery of the malarial parasite by LAVERAN; (2) the discovery of its developmental cycle in man by GOLGI; and (3) the discovery of its developmental cycle in the mosquito by ROSS. Other observers who had assisted towards the progress of this knowledge had been MACCULLUM, MANSON, BASTIANELLI, BIGNAMI, and GROSSI. Our knowledge at present on the mosquito theory may be put shortly in non-technical language. We now know that when a mosquito of the species *anopheles claviger* sucks blood from a human being infected with malaria, the parasites underwent a cycle of development in the body of the insect, which is completed in from one to three weeks, according to the temperature, and results in the formation of a large number of minute embryo parasites—blasts—which find their way to the cells of the salivary glands, from which, together with the saliva, they pass into the next animal or man bitten by the mosquito, and there set up a malarial infection characterised by the parasites of LAVERAN, pursuing the developmental cycle described by

GOLAI, and ready, as soon as mature, to infect the next mosquito sucking the blood. There was thus an alternating series of infection—man, mosquito, man, mosquito, &c.—going on *ad infinitum* until cold weather or other accident destroyed the mosquitoes or made them inactive. In order, therefore, that a person shall be infected with malaria, it was necessary that he shall be bitten by a particular kind of mosquito after a definite length of time after it has become infected by the blood of a malarial patient. The essential was the presence of the *blasts* in the saliva of the mosquito, and these occurred only in infected mosquitoes. Anopheles mosquitoes bred from the larva were harmless until accident brought them to some one suffering from malaria, and then, after one to three weeks, they were ready to infect every one they bit. The ability to infect is not imparted by the mosquito to its offspring. It was not impossible that malarial infection might take place in other ways than by mosquito bites, but the collected experimental evidence made this so improbable that it could almost be denied. Certain districts, and particularly marshy districts, were malarious, because the appropriate mosquitoes inhabited them. Such localities were sometimes free from the disease, because the mosquitoes were not infected. They might suddenly become the hot-beds of the disease by the advent of some temporary or permanent visitor with malaria by whom the mosquitoes became infected. Tropical climates, summer seasons, warm weather and dampness, all favored the disease. The autumn was the most malarial season, because there were more mosquitoes then, and because more of them had had the opportunity to become infected. Infection took place at night rather than the day time, because mosquitoes were nocturnal in their habits. Infection occurred near the ground, because mosquitoes frequent lowlands and do not fly high. It occurred in rooms with open windows, as the mosquitoes could readily enter. Still atmospheres propitious to it, for mosquitoes sought shelter from the wind. It was carried but a short distance by the wind, because mosquitoes avoided flying in the wind. Its occurrence was favoured by turning up the soil because of the occurrence of puddles in which the insects breed. It disappeared from marshy districts after they were drained, because the mosquitoes no longer found breeding places there. It disappeared when the soil was well tilled, because their breeding places were interfered with. The disease was readily transported from place to place by sufferers from it seeking salubrious localities, and by the transportation of mosquitoes in carriages, railroad cars, &c. The disease had an incubation of some days, so that its development in a patient at one place might not mean that it was not acquired at another place. From being thought to be due to bad air, it was now known that malaria was a specific infectious disease, and that the air had nothing to do with it.

Etiology of Gall-stones.

FREDERICK C. SHATTUCK (*Philadelphia Medical Journal*) says that little is known of this subject. What we do know is that (1) gall-stones are composed mainly of cholesterol, often partly of biliverdin calcium precipitated by changed reaction of the bile. A nucleus may be formed of biliverdin calcium, bacteria, a foreign body, or a combination of these. (2) Gall-stones, while not unknown in childhood, are rare under the age of thirty years; from thirty to sixty they are more common, little difference existing between the several decades of this period in point of frequency; after sixty they are more common than in earlier life. (3) They are from two to four times more common in women than in men. Stasis of the bile is a very important etiological factor, and the chief causes of this seem to be, in the writer's opinion, tight lacing and want of exercise, and typhoid fever. He thinks we can get rid of the latter cause more easily than of the former.

COMMENTS AND NEWS.

I. M. S. COMPETITIVE EXAMINATION—AN APPEAL TO GOVERNMENT FOR A LOCAL TEST.

INDIAN MEDICAL ASSOCIATION.
OFFICE : 50, PARK STREET, CALCUTTA.

20th February 1901.

TO—W. R. LAWRENCE, Esq.,

Private Secretary to H. E. the Viceroy.

DEAR SIR,

At the request of the Council of the Indian Medical Association, I beg most respectfully to place the subject-matter of this letter before you, in the hope that it may meet with consideration by His Excellency the Viceroy. It is also hoped that the urgency and importance of this question will be deemed a sufficient plea for this direct appeal to His Excellency.

A statement has appeared in the public Press, to the effect that the Government of India is desirous of employing twenty medical men in India for vacancies in the Indian Medical Service on salaries of Rs. 600 and Rs. 500 monthly, according to their qualifications. It is further announced that candidates for such employment will be engaged for twelve months only, the Government reserving to itself the right to terminate such engagement by a month's notice.

These posts are offered only to men possessing British medical diplomas, special terms being allowed to those holding diplomas in Public Health.

The Council of the Indian Medical Association feel assured that no medical man possessing the above qualifications, practising his profession in India, will be likely to accept temporary employment in the I. M. S. The Council feel certain, however, that, were permanent employment in the I. M. S. offered to graduates of our Indian Universities, men, suitable in every way for such posts, would soon be forthcoming.

The Council desires it mentioned that under the amended Medical Act of Great Britain, of 1894, graduates of Colonial and Indian Universities are empowered to register their degrees and diplomas on the *British Medical Register*, and that, under Para. C, Rule 4 of the "Regulations for examination of candidates for appointments in the I. M. S.," "a certificate of registration under the Medical Act, of the degrees, diplomas, and licences possessed by the candidate," is the condition which qualifies for appearance at the competitive examinations held half-yearly in London, and that there is therefore no legal barrier to graduates of Indian Universities being accepted as candidates for the I. M. S. by virtue of their registered Indian diplomas alone.

Hitherto candidates from India have been, and are still, compelled to go to London to appear in the I. M. S. competitive, held there half-yearly in the months of February and August. To certain vague reasons, which the Medical Press in London ascribes as the cause of the growing unpopularity of the I. M. S., there has recently, and for the past few years, been declared to be dearth of suitable candidates in England for the I. M. S. Under the circumstances, it has been considered by the Council of the Indian Medical Association that an appropriate means of meeting this difficulty would be the reservation of a certain number of vacancies in the I. M. S. for competition among graduates of Indian Universities, the tests of fitness being similar to those now applied to candidates in the London competitive.

It is felt that such a concession on the part of the Government of India would not only be an act of justice towards

the medical colleges of India and the medical profession in this country, but it would undoubtedly prove a most encouraging stimulus to elevating the tone and the status of the medical profession in this country, and this would tend to the public good.

I am, dear Sir,

Yours faithfully,

JAMES R. WALLACE, M.D., F.R.C.S.,
Secretary, Indian Medical Association.

A PARADISE OF SPINSTERS.

THE *Philadelphia Medical Journal* says:—The celibate tendency of the modern woman is beginning to worry the vital statistician. The decadence of marriage is threatened, and the gradual extinction of the race. Mr. CARROL D. WRIGHT has been investigating the subject, and finds that of 17,427 representative working women, living in 22 cities, 75% of them being under 25 years of age, 15,337 were single women. These figures are simply appalling. In the good old times, it is claimed, one-half of these young women would already have been married from three to five years. The fact seems to be that there is a tendency to the postponement of marriage on the part of both sexes. In the case of women this postponement is too often fatal, and in the case of men it gets to be a bad habit. But the evil being recognized and reduced to figures, the next natural thing to do is to seek for the causes of it.

Several theories have been advanced to account for this increasing unpopularity of marriage. The statement that young men have become more shy and embarrassed in the presence of the modern go-ahead girl, may have some truth in it. The present tendency is undoubtedly to cultivate self-assurance and independence in young women, and to encourage them to become self-supporting. Many avenues are open to them; they can make a comfortable living and enjoy life. Many a woman, in fact, can make a better living for one than the majority of young men can make for two (with prospects of more). This situation tends to check marriage in two ways: First, it makes the women more independent of men, and, therefore, in the second place, perhaps a trifle less attractive to them. Marriage is an odd affair, anyhow. It is largely a psychical business at the start, based upon a delicate emotional instinct; and all the logic and reason of a progressive age cannot alter that fact. The pushing and business-like modern woman is not conducive to it.

The competition and the stress of modern life are deterrent to matrimony. Every one can see this in his daily observation. How few men are able properly to marry before they are 35 or 40. But by this time the girl companions of their youth are almost fitted to become grandmothers. We would suggest to Mr. WRIGHT that he should write up the statistics of bachelors—both young and old (if any of the latter can be found). In France a law has been introduced into the Senate to tax all celibates over the age of 30, and all married couples who remain childless after five years. We heartily approve of this plan. Let these people contribute to the support of other people's families if they persist in not having any of their own.

GREATEST ADVANCE IN SCIENCE IN THE NINETEENTH CENTURY.

THE *London Spectator* says that there can be little doubt that nine men out of ten, if asked what was the greatest idea which science had introduced into the world in the nineteenth century, would answer "Evolution." On the whole, we think they would be right. DARWIN holds in the

scientific world of the nineteenth century the place which NEWTON had taken in the seventeenth; with a patience and an insight conjoined only once in an age, he gave a clear and persuasive account of the way in which one step in the great world process of evolution might have come about. The nineteenth century will ever be remembered as the age which established the doctrine of evolution, and Englishmen will be justifiably proud to think it will be coupled to all time with the name of DARWIN. When evolution is mentioned, three other names will immediately occur to one's mind—those of HUXLEY, of SPENCER, and of WALLACE. The publication recently of the "Life of Huxley" has aroused fresh interest in that philosopher, and, considering that he was a member of the medical profession, interest in him and his doings will partake of a somewhat personal nature. If it had not been for HUXLEY's unceasing labors in spreading abroad the Darwinian theory, it is more than likely that evolution would have fallen flat, or at any rate would not have attracted the attention of the general public so quickly and so widely as it has.

By some HUXLEY was known as the "great apostle of evolution;" he termed himself DARWIN's bull-dog, and right ably did he perform bull-dog work in exhibiting and making clear to the man in the street the true interpretation of the "origin of species." For long he had to contend against religious prejudices, and his famous discussion with the late Bishop WILBERFORCE will not be soon forgotten. The Bishop, who was the most witty and eloquent English churchman of his time, and who was commonly known by the not altogether complimentary sobriquet of "Soapy Sam," jeered HUXLEY for endeavoring to propagate so absurd an idea as that of evolution, and wished to know whether it was through his grandfather or his grandmother that he claimed his descent from a monkey, to which HUXLEY retorted: "I asserted, and I repeat, that a man has no reason to be ashamed of having an ape for his grandfather. If there were an ancestor whom I should feel shame in recalling, it would rather be a man—a man of restless and versatile intellect—who, not content with an equivocal success in his own sphere of activity, plunges into scientific questions with which he has no real acquaintance, only to obscure them by a nameless rhetoric and distract the attention of his hearers by eloquent digressions and skilled appeals to religious prejudice." The verdict of posterity upon both DARWIN and HUXLEY among thinking men, irrespective of their theological convictions, will assuredly be that they were scientists of the very first rank who shed lustre on the nineteenth century.

TEACHING OF ANESTHESIA.

THE *Philadelphia Medical Journal* says:—All experienced surgeons realize the great importance of a careful administration of anesthetics, and all physicians at some time during their professional careers are likely to be called upon to administer anesthetics. In spite of the need of experience and of special knowledge for the successful administration of anesthetics, very little attention is paid to the subject in most of our medical schools, and in hardly any, if any, is there an opportunity for gaining a practical knowledge of the subject. Even in England, where professional anesthetists are generally employed, it seems that the attention paid to the subject has not been very great in the past. In a letter to the *Lancet*, November 10, 1900, DUDLEY BUXTON, lecturer on anesthetics in the University College Hospital, London, expresses his satisfaction that more attention is being paid to this subject in the English medical schools than formerly, and emphasises several

important points in this connection. He believes that it is absolutely necessary for students actually to give the anæsthetic under supervision during their instruction, and that physicians and surgeons should recognise the importance of the subject. The students should not only give the anæsthetic, but should examine their patient before and after its administration; they should study any noteworthy differences from the normal, and be taught to make a careful choice of anæsthetic.

The skilful anæsthetist should have sufficient knowledge of medicine to conduct an accurate physical examination, including that of the blood and secretions. His familiarity with surgery should enable him to know what the operator requires, and what will be the effect of the operator's manipulations upon the patient under anæsthesia, and also the requirements as to relaxation of the patient for special operations. His knowledge of anæsthetics should be such that he can adapt the anæsthetic to the necessities of the patient and the requirements of the surgeon. The old days have gone by when anyone, from the house-surgeon to the ward-nurse, can be considered competent to administer anæsthesia, while the operating surgeon "keeps his eye on the patient." The faculties of our medical schools should recognise the tremendous responsibility of the anæsthetist, and the fact that all graduates are likely to be called upon to use anæsthetics and in most cases quite frequently. Lack of knowledge or skill may jeopardize the patient's life and frustrate the surgeon's most skilful endeavors. The facilities for teaching this subject should be increased; it should be made compulsory, and the opportunity for hospital training should be given. In this way the students of the future will graduate much better equipped in a very important requisite than their predecessors have been.

MORTALITY AND MORBIDITY OF PHYSICIANS.

ALFRED MOEGLICH has collected a series of statistics which give results sufficiently discouraging to the medical practitioner who aspires to reach the scriptural age of threescore and ten. Of all the professions, medicine offers its devotees the least promise of a ripe old age, the averages time of death varying from fifty-two to fifty-six years, according to different authorities; while for the clergy, for example, it is ten years later. The combination of pedagogy with medicine appears to be particularly fatal, for one set of figures in which the normal death-rate is represented by 100 gives 111 as the factor for physicians, and 113.8 for medical instructors. Of the causes of death, infectious diseases rank highest, and among these typhoid fever occupies so prominent a place as almost to entitle it to characterization as an occupation disease. Tuberculosis comes next, the death-rate from this cause among physicians being almost double that of the clergy. Altogether it is rather a melancholy fact to realize that the men whose life-work it is to teach others how to keep their health, or to regain it if lost, should themselves be unable to profit by their own knowledge, and should be so completely at the mercy of the great bodily and mental stress to which their calling subjects them.

TO BANISH THE MOSQUITO.

The Medical Record of New York says:—The vastly increased importance to humanity, which the mosquito has assumed during the past year, renders all that pertains to this pest peculiarly interesting at the present time.

While it is not strictly new or novel, it is still noteworthy as being communicated to the State department in Washington by Consul PLUMACHER, of Maracaibo, that the

ricinus communis or castor-oil plant is so distasteful to the insect that it will remain neither about premises where these trees are planted, nor in apartments where the cut branches, leaves, and seeds have been exposed.

Even in cold climates it is said that plants four or five feet in height can be raised from the castor seeds, and under favourable conditions will grow in great profusion. If the personal experience of Consul PLUMACHER in keeping his household free can be duplicated by each future experimenter, sleepful nights and freedom from malaria may still be within the grasp of all who dwell in regions where the tuneful piper loves to exercise his prerogatives.

The castor plant has already done much for man. If this boon is added, we can well afford to toast it in a large bumper of its own oil.

DIABETES MELLITUS IN CHILDREN.

DR. LEOPOLD F.W. HAAS, M.D., in an address to the Section on Diseases of Children at the fifty-first annual meeting of the American Medical Association held at Atlantic City, New Jersey, a report of which appears in the *Journal of the American Medical Association*, referred to the subject of diabetes mellitus in children. We extract the essentials. The etiology of this disease was, owing to its rarity, obscure in children. Heredity played an important part in its causation, while a family history of insanity, phthisis or gout was frequently obtainable. The patients generally belonged to the wealthier classes, and Jews were often the sufferers. The speaker gave the history of two most interesting cases occurring in his own practice, which did not follow the usually fatal course indicated by ROBERT SAUNDY, viz., that "in children and young persons diabetes is an acute and rapidly fatal disease, lasting only weeks or months, or at most one or two years, but cases have been known to extend over five, six or more years." A very few cases had been reported as cured. The speaker's two cases were interesting for several reasons. There was well-marked family history of tuberculosis in both on the maternal and paternal side. In neither could it be said how long sugar had been present in the urine—a fact much to be regretted. In one case there was the history of an injury sustained a year before sugar was first noticed in the urine. Whether this injury had any etiologic significance or not was, of course, uncertain. In the other case there was also a history of pectoris rheumatica, with an eruption, joint pains, fever and a tumultuous action of the heart. It was questionable whether the two affections came on simultaneously, or whether the diabetes existed before the rheumatic attack. The speaker's conclusions were: (1) Diabetes occurs more frequently in children than is generally supposed. (2) Urinalysis is just as important an element in the scientific diagnosis of disease in children as it is in adults. It is to be regretted that the general practitioner rarely realizes this fact. (3) There is a possible etiologic connection between pectoris rheumatica and diabetes. The pathogenesis of both conditions is so obscure, however, that speculation on this question can only point out a direction for further research.

EYE-STRAIN.

DR. W. E. HAMIL, M.D., Toronto, touches on the subject of Eye-strain in the columns of the *Canadian Practitioner*. We summarize. Every organ, it was pointed out, required a certain amount of nerve force, in order that the functions of the organ should be properly carried on, and if the nerve stimulus was interfered with or withdrawn from any

organ, it resulted in erratic and disordered functioning of this organ, causing more or less disturbance in the whole body. This was what happened in the case of the eye. This organ was connected by numerous nerves (wires) with the brain (battery), and in every act of vision, "fixing" of the sight, and movement of the eyeballs, there was a supply of innervation (electricity) needed and used up, and as the eyes during waking hours were constantly receiving images and moving in different directions, it was plain an immense supply of nerve force was required by them every day. The brain was quite equal to the demand, however, in the emmetropic and orthophoric eye: but supposing either ametropia or heterophoria existed, then a disturbance of the nervous equilibrium of the whole body was continuously produced, with the result that from the greater demands of the ametropic or heterophoric eye some organ of the body was likely to suffer, and hence it was not surprising to see stomach, intestinal, heart, lung, ovarian and such like troubles disappear, when the equilibrium was again restored by means of spectacles or prisms. The writer had seen frequent cases of obstinate dyspepsia, constipation, palpitation, asthma, epilepsy, etc., cured entirely simply by means of a proper pair of spectacles. Headaches were especially due to "eye-strain," and probably 80 per cent. of all chronic headaches were due to some form of eye trouble, requiring glasses as the remedy. Surely the time had arrived when every physician should recognize that persistent, oft-repeated headache should be the torch-light to pilot the patient to an oculist, instead of giving them medicine, which was not only usually inefficacious, but absolutely pernicious.

PERSONAL PROTECTION AGAINST MOSQUITOES.

J. A. WEGG, M.D., (*British Medical Journal*), says:—Believing it may be of some interest and value to the members of the British Medical Association who have not given it a trial yet, I wish to record my experiences during the last few months in the use of the ordinary kerosene oil (which is sold here at 4d. a quart) as a simple and inexpensive and reliable means of personal protection against the mosquito. That is readily effected by sprinkling some of it all about the sleeping chamber, or cab in, or bunk, and tying a handkerchief or clean towel nearly saturated on the bedposts, etc., above the head of the occupant, due caution being of course taken not to bring a light too near. We have found it a very excellent adjunct to the mosquito net which is generally recommended and used, and may under certain circumstances fairly become a substitute thereof, where in a way somewhat similar to the method of Dr. STANLEY HAYNES there is no mosquito netting. He, however, used surgical carbolic soap, locally applied to the face, neck, hands, and forearms. I have likewise used a solution of carbolic acid in the same way as above mentioned for kerosene oil, and with great satisfaction. But I prefer the latter agent, because it is not only cheaper, but innocuous—an important point amongst an ignorant and careless population, such as we have to treat here: besides it is fully as effective. I am inclined to believe that the kerosene drives away the mosquitoes, owing to its peculiar penetrating odour overstimulating their olfaction, and causing them to flee from the source of the irritation.

TOO MUCH QUALIFIED.

It appears from an editorial note in the *Medical Press and Circular* that it is possible to be too well fitted for a medical position in Great Britain. In a recent competition for the position of resident house physician at Cardiff, Wales, the rejected candidate showed higher qualification

than his successful rival. When the selection was challenged, it was argued on the part of the medical board who made the choice "that when a man who was head and shoulders above his commanding officer was appointed to a subordinate post, there could be no discipline." In other words, the lack of medical qualification of the superior officer should deprive the institution of the services of any better-qualified employé—the better qualified the worse fitted for the place. The plea that discipline would suffer under such conditions is an admission of executive incompetency or a slur on the loyalty and good faith of the better-qualified candidate, and is contemptible in either case. The fact that the resignation of the medical board was threatened when the directors overruled their rejection of the candidate does not speak well for their professional or scientific morals. Moderation in all things is sometimes good advice, but we never knew it applied especially to professional qualifications before.

JOIN THE INDIAN MEDICAL ASSOCIATION.

Rise! for the day is passing,
And you lie dreaming on;
The others have buckled their armour,
And forth to the fight are gone:
A place in the ranks awaits you,
Each man has some part to play;
The Past and the Future are nothing
In the face of the stern To-day.

Rise from your dreams of the Future—
Of gaining some hard-fought field;
Of storming some airy fortress,
Or bidding some giant yield;
Your future has deeds of glory.
Of honour (God grant it may!)
But your arm will never be stronger,
Or the need so great as To-day.

A. A. PROCTER.

I.M.S. MEN AND PRIVATE PRACTICE: LAHORE COLLEGE PROFESSORS NOW PROHIBITED.

LIEUTENANT-COLONEL, I.M.S., writes to us as follows:—

I have read your article in the *Indian Medical Record* re I.M.S. men and private practice.

"It may strengthen your hands to know that by a recent order—and for the very reasons urged by the *Indian Medical Record*—the Punjab Government have entirely prohibited general private practice to the following professors in the Lahore Medical College:—

The Professor of Chemistry.
" " " Anatomy.
" " " Physiology and Botany.
" " " Pathology and Materia Medica.

These professors are only allowed consulting practice. The Professors of Medicine and Surgery (unless one happens also to be Principal) are, curiously enough, still permitted general practice. I may tell you on the highest possible authority that the Lieutenant-Governor failed absolutely to see the reason of these exceptions; but, as large personal interests were involved, the specious arguments of the Head of the Department succeeded in getting the Lieutenant-Governor to withhold the prohibition in the case of these two men.

Surely if the Lahore professors are not now allowed general private practice on the ground that their public duties are likely to clash with the claims of private practice, the reasoning applies with immensely greater force to the Calcutta men."

Our correspondent continues: "You have but to keep on hammering away for a little while longer, and I.M.S. men will be relegated to their legitimate field of extra-official work—namely, *purely consultative practice*."

We may add in this connection, and for the information of His Honor the Lieutenant-Governor of Bengal, that so conscientious and experienced an officer as Colonel G. BOMFORD, M.D., Lond., I.M.S., Principal of the Calcutta Medical College and Senior Physician to its Hospital, though privileged to engage in *consultative practice*, refuses to do so, on the ground that such work would interfere with his public duties!

INFANT MORTALITY IN BOMBAY.

THE infant mortality in Bombay city is terribly high, and, as Colonel DIMMOCK remarked at a meeting of the Corporation, is a standing disgrace to that body. The mortality returns show that seven infants are born to die each day, in addition to which there is a very high mortality among women during child-birth. Some time ago a Committee of the Corporation, including nearly all the members who belong to the medical profession, was appointed to consider the question, and recommendations were made that the Corporation should engage the services of a skilled midwife for each ward, involving an expenditure of Rs. 8,000 annually. Dr. VIEGAS moved the adoption of the report, but ultimately it was decided merely to record the suggestions of the Committee. There was a long debate on the subject, and it was urged that the great infantile mortality was largely due to the insanitary surroundings in which they were born, and among those urging this view was Dr. ISMAIL JAN MAHOMED. Colonel DIMMOCK and other medical men, however, are of opinion that the chief reason is due to ignorance and unskilful nursing at time of birth.

THE OFFICIATING "PROFESSOR" OF SURGERY IN CALCUTTA.

"PROFESSOR" R. D. MURRAY, of the Calcutta Medical College and Hospital, has left India for eight months, and as no senior I. M. S. man could be found to fill his place, a junior I. M. S. man, in the person of Captain R. BIRD, the Resident Surgeon of the College Hospital, has been appointed to officiate for Dr. MURRAY. There can be no question as to Dr. BIRD's excellent academic qualifications, but there is also similarly no doubt that he is too junior a man for so important and onerous an office, for he lacks experience, and this is a positive disqualification. Things have reached an extreme pitch of helplessness, when the Director-General, I. M. S., fails to find, among the large number of officers in the Government service, one fit in every way to suitably and efficiently fill a vacant surgeoncy in the Calcutta Medical College Hospital.

Just fancy the idiocy of sending both the surgeons of a large public hospital away on leave *together*.

AN APOLOGY FOR LECTURES.

DR. G. V. POORE says:—"Lecturing is not reading. The man who keeps his nose on a manuscript while his audience takes a nap might well be replaced by a phonograph with a text-book in its magazine. The functions of a lecturer are different from those of a text-book. The lecturer has power of selecting his material, and he must be able to keep in touch with his audience. He knows at once when his audience are interested and when they are bored. A lecturer who fails to maintain order in his class has probably mistaken his vocation."

He speaks enthusiastically of the lectures of Sir WILLIAM JENKINS and Professor SHARPEY. But of others which he attended he says, "they proved too soothing even at 9 A.M. Some were thoroughly bad, more incoherent and incomprehensible drivel." He quite candidly asks the reader to interpret the word 'attended' in a 'scholastic' sense!

But even in his opinion "the medical student is still a very much lectured individual."

A PROTEST AGAINST FALSE ECONOMY.

DR. W. G. KING, C.I.E., Sanitary Commissioner, Madras, speaks very plainly on the undesirability of under-paid Sanitary Inspectors:—"It is of the utmost importance that, in making this new effort in sanitary advance, District Boards should not make the irretrievable mistake of lanning upon the people an ill-paid class of subordinates. A class of men of respectable origin can be induced to join by the offer of fair pay, and can maintain that respectability; but it requires but a feeble knowledge of Indian life to know what would be the result of what should be a most valuable movement, if poor pay is to be offered."

SHORT ITEMS AND PERSONALITIES.

An official telegram from Colonel Ternan, dated Afnadu, the 24th instant, states that Lieutenant-Colonel Maitland, I.M.S., was killed in the action of the 16th, together with his syce, and also a number of native troops killed and wounded. Among them were Solomon Aran, 1st class Hospital Assistant.

It is stated that on his retirement from the appointment of Residency Surgeon at Hyderabad, Colonel Lawrie, I.M.S., will be asked to continue as Director of the Nizam's Medical Department.

Mrs. A. E. Edge, I.M.S., who has just been appointed a Fellow of the Bombay University, is the first lady who has been thus honoured in the whole history of the Indian Universities.

The streets of Calcutta, owing to the census operations, presented a remarkable appearance after nine o'clock on Friday evening. With the exception of policemen, not a human being was to be seen. Calcutta seemed to be a city of the dead.

In hip-joint disease the pain first complained of may be on the inner side of the thigh, or above the patella, or in the popliteal space, or about the knee, wherever the terminal branches of the obturator nerve are distributed.

It is understood that leave is to be reopened to officers of the Indian Medical Service in civil or military employ to the extent that officers can be made available to replace absentees.

"I hardly know any more potent cause of disease than alcohol. It is the most destructive agent we are aware of."

SIR WILLIAM GULL, F.R.S.

"It is capable of proof beyond all possibility of question that alcohol in ordinary circumstances does not help work, but is a serious hinderer of work."

SIR ANDREW CLARK, M.D., F.R.C.P.

The Government of India have sanctioned the formation of four additional native field hospitals, and a grant has been made to enable their equipment to be commenced at once.

Captain Hoare, I. M. S., Residency Surgeon, Persian Gulf, has been granted furlough for nine months, and Captain W. J. Grant, I. M. S., officiates.

WANTED—A POST BY AN ASSISTANT SURGEON willing to serve in a Native State in the Railways or any Municipality, &c. Apply V., C/o The Manager.

Members of the Indian Medical Association will kindly note that while the entrance fee to the Association is fixed at Rs. 5, the annual subscription is reduced to Rs. 2.

Current Medical Literature.

MEDICINE.

Etiology of Stuttering.

MYGIND, of Copenhagen, since the establishment by the Danish Government in 1885 of a course for the treatment of the stutters, has served as the medical member of the national commission appointed to look after the interests of these defectives. During this period he has made a careful examination of two hundred cases of children and young people between six and twenty-five years of age.

The causes of stuttering the author divides into the customary classification of remote or disposing, and immediate. Under the disposing causes he gives consideration to: (a) The influence of sex; (b) the influence of age; (c) heredity; (d) certain diseases of the nose, nasopharynx, and pharynx; (e) certain constitutional diseases; and (f) finally, a few other remote conditions having an etiologic influence. Under active causes he cites: (1) The so-called psychical infection (contagium morale); (2) the infectious diseases; (3) trauma; and (4) certain psychical influences.

It is an old and well known fact that a large percentage of stutters are of the male sex. GUTZMANN, in examining school children, found that seventy per cent. of the stutters were boys; among adult stutters, that ninety per cent. were males. MYGIND's cases showed eighty-five per cent. of males. The age at which the speech defect was first noticed was in most cases before the sixth year—that is, during the period that speech would naturally be acquired. He noticed, however, that stutters learned to speak, as a rule, much later than children free from speech defect.

Heredity plays a not unimportant rôle. No less than 85 of the 200 cases—that is, forty-two per cent.—had relatives who were at the time, or had previously been, stutters. In fifteen cases there was mental disease among the pupils' relatives. Five of the pupils had idiotic relatives. Epilepsy was noted among the relatives of thirty-two pupils. Various other unclassified neuroses were present among the relatives of twenty-nine per cent. of the pupils.

MYGIND found, with others who have studied similar cases, that stutters very frequently suffer from some pathological condition in the nose or pharynx. Adenoid vegetations were especially common, being observed in thirty-nine per cent. Psychical infection could be traced in thirteen per cent.—that is, they became stutters through direct association with other stutters. A few cases seemed to arise from other psychical causes, such as fright and the nervous disturbance naturally caused in a child during its first weeks at school.

In conclusion, the writer lays considerable stress upon the signs of nervous degeneracy to be noted among stutters and their relatives, which he regards as a very potent etiological factor in the production of this speech defect.—*Med. Age.*

Hæmaturia attending Tuberculosis of the Kidney.

NEWMAN (*Lancet*) points out that hæmorrhage from the kidney occurs: (1) In consequence of injury, independently of any pre-existing tuberculous lesion, the effused blood or injured tissues forming a nidus for tuberculous infection; (2) as a premonitory symptom of tuberculous disease long antecedent to the development of a gross renal lesion; and (3) in consequence of destructive tuberculous processes in the pelves or the parenchyma of the kidney. He reports cases illustrative of each of these varieties of hæmaturia. The following method for detecting tubercle bacilli in suspected urine is recommended: A quantity of urine is permitted to stand in a conical glass in a cold place for not more than six hours, and from the deposit a small quantity

of debris is selected and placed in a glass of 0.75 per cent. salt solution. The deposit is, however, obtained more rapidly and more reliably by centrifugation, which should always be resorted to when the number of bacilli is supposed to be small, or when the urine contains much mucous or blood. When the mucous is considerable, it may be necessary first to render the urine slightly alkaline. A small amount of the sediment is placed on a cover slip and spread in a thin layer by pressure through a second cover slip. The slips are dried in the air, and they may be more firmly fixed over a spirit lamp or in front of a fire. They are then placed in, or floated, face downward, upon a solution of aniline magenta or of gentian violet. Decolorization is effected by passing the cover slip through a twenty-five per cent. solution of nitric acid, and then washing in water. Tubercle bacilli are cultivable from urine only with difficulty. Their presence may further be demonstrated by animal inoculation. When the existence of tuberculosis has been demonstrated, it is important to determine whether one or both kidneys are affected. This may be done by catheterization of each ureter separately, and an individual study of the secretion from the corresponding organ.

Filarial Origin of Elephantiasis.

DANIELS believes in the filarial origin of elephantiasis. In support of this view he calls attention to the fact that the filaria nocturna and elephantiasis have the same geographic distribution. As to the question of racial incidence, his investigations show that while some races are rarely attacked, in others elephantiasis is common, and that among the natives the women are more frequently attacked. In filarial disease the relative incidence varies in the same manner as the incidence of elephantiasis. This strengthens the view of the dependence of the one upon the other. The cause of difference in the racial incidence depends: (1) On the presence of the infected primary hosts; (2) on suitable intermediate hosts; (3) on the water-supply, in connection with which storage in small receptacles is practised, allowing of the ready deposit and concentration of the intermediate hosts, with their embryonic contents. In reference to the pathology of the lymphatic obstruction, evidence is adduced to show that the parent worm can cause obstruction by exciting hæmorrhage, or frequent attacks of lymphangitis, or that the embryos may be discharged into the lymph-stream while in their egg-capsules, in which case they would from their size be stopped at the next lymphatic gland, and thus cause obstruction. As to the variety of forms of filarial disease in Guiana, the regions of the body attacked are much the same as in other countries where elephantiasis is common.—*Phil. Med. Jour.*

On Intermittent Pulse.

ARTHUR B. CUSHNY believes that intermissions of the pulse may be divided into several classes: (1) True ventricular intermissions, in which the pause is exactly equal to two pulse intervals, and during which there is no cardiac sound; (2) true auricular intermissions, in which the pause is shorter than two pulse intervals, and during which there is no cardiac sound; (3) false ventricular intermissions, in which the pause is equal to two pulse intervals, but is often interrupted by a slight elevation; (4) false auricular intermissions, in which the pause is shorter than two pulse intervals; (5) another form which has been described by WENCKEBACH. The treatment of cardiac disease may be rendered more exact by the careful examination of the pulse, which may indicate whether the existing condition is that of excessive irritability or of deficient activity.

SURGERY.**Otitis of the Exanthemata.**

J. HENRY FRUITNIGHT (*Medical News*) says:—In personal experience, covering a quarter of a century and embracing nearly five thousand cases of the exanthemata, especially scarlet fever and measles, otitis media has been met with as the most frequent of the various complications which may occur during the course of the exanthemata. If the attack be treated immediately upon its appearance, it is not necessary to call in the aid of an otologist. First, it is extremely important that scrupulous attention be given to the active treatment of the nose and throat in these cases, for thereby an attack of otitis is very often prevented. In regard to the question of paracentesis tympani, it is not always necessary to incise the drum-membrane. If, however, on inspection it is found that the tympanum is projecting and is highly congested, and the patient is frantic with pain, then the membrane should be incised to relieve the engorged blood-vessels. The effort, however, should always be made to abort the attack and to hinder suppuration and perforation. Those patients who are subjects of a constitutional taint, and in whom the otitis has been left untreated and allowed to go on to perforation, are very apt not to get well, but become chronic cases and lose their audition. For the accompanying otorrhoea, the following plan of treatment has been found valuable: First, 5 drops of peroxide of hydrogen are instilled in the ear; after a few minutes this is flushed out with lukewarm water until the water returns clear, free from all turbidity; the canal is then carefully dried out with pledgets of absorbent cotton. Then 3 drops of an alcoholic solution of boric acid are put in the ear and allowed to remain there. The strength of this solution is from 5 to 10 grains to the ounce of alcohol. In most cases this treatment has been successful in checking the purulent or sero-purulent discharges, though the nurse is cautioned that the treatment must not be discontinued so long as there is a vestige of the discharge.

Radical Cure of Hydrocele.

DR. ORVILLE HORWITZ, in *Journal of Cutaneous and Genito-Urinary Disease*, says:—Incision with partial removal of the sac is to be resorted to when the sac is found to be thickened, or where it protrudes far into the inguinal canal. A modification of this operation is suggested, which, it is believed, will greatly simplify the usual procedure. It is performed by making a free incision over the long axis of the tumour, dividing the structures down to the sac, at the same time being careful not to open it. By means of an ALLIS's dry dissector, the scrotal tissues are quickly separated from the tunic, which is left slightly adherent posteriorly; this being the portion of the sac which covers the cord and is not disturbed. The sac is then made tense, fixed by means of a tenaculum, opened by a touch of the knife, and the fluid allowed to escape. The sac, having been thoroughly dissected from the scrotal tissues, is removed in a single piece by means of the curved scissors. The bleeding vessels are ligated and the wound dried. Should there be much hemorrhage from the edges of the cut sac, it must be controlled by a continuous suture passing completely over the margin. The portion of the tunica vaginalis lying over the cord is swabbed with carbolic acid, the wound irrigated with 1 to 1000 bichloride solution, a small drainage tube inserted, and the parts closed by silk-worm-gut sutures. An antiseptic dressing is then applied. The drainage tube is removed after twenty-four hours; the sutures after the seventh day.

Unrecognized Syphilis in an Infant: Infection of the Nurse: Multiple Chancres of the Breasts.

DANLOS describes the case of a healthy woman who became wet-nurse to a premature infant eight days old, apparently well. Within three weeks the child showed all the symptoms of a severe congenital syphilis, and died a week later. Eight days after the baby's death the nurse had one chancre on the left breast, and twenty-one ulcerating sores, indurated and round, on the right. In the right axilla the lymph-nodes were indolently enlarged. The mouth and genitals were normal, and the woman never had any generalized eruption, but severe headaches at night and malaise. While chancres of the breast are usually multiple, it is rare to find them so numerous as in this case. The parents of the baby denied all history of syphilis, but the lesions in both child and nurse were unmistakable.—*Archives of Pediatrics*.

Submersion in the Treatment of Wounds.

THE use of the hot bath in poisoned wounds, to which attention has recently been called by FRASER, is here noticed by HODGES, who claims that he has been the only American advocate of the treatment since the publication of Dr. FRANK HAMILTON over twenty-five years ago. His extensive experience with the procedure, he claims, warrants the following practical conclusions: (1) Continuous submersion even for long periods—two or three months if necessary—is altogether harmless. (2) That it may be easily secured anywhere by anybody possessing an ordinary degree of ingenuity. (3) It will almost instantly limit infectious gangrene and control the resulting septicemia and pyæmia. (4) It will quickly relieve the pain and discomfort of phlegmonous inflammation or cellulitis. (5) It will speedily and readily reduce temperature and pulse and overcome the consequent depression of the patient's vital forces. (6) The temperature of the bath is immaterial, except when below that of the room, it more promptly reduces fever, and many bacteria will not develop at this temperature, while such as do so, develop less vigorously than at a slightly higher temperature.

Seminal Vesiculitis.

IMPOTENCE, according to GUTESBAS, is largely due to inflammation of the seminal vesicles, though there may be other predisposing causes such as chronic inflammation of posterior urethra, chronic prostatitis, varicocele, etc. He reports cases illustrating his views and the treatment of the condition, which is a sedative one, at first avoiding anything that is stimulating or exciting in the sexual sphere, with internal remedies to neutralize the urine in case of over-acidity. He uses rectal irrigation every night, with normal salt solution or strained flaxseed at a temperature of 105 to 120°F., by means of the double-current rectogenital tube and massage of the internal genitals every five days, followed immediately by urethral irrigation whenever there is chronic prostatitis and posterior urethritis associated with the condition. After the irritation and inflammation have been removed, stimulation by drugs, electricity, and regulation of hygiene is employed.

OBSTETRICS AND GYNECOLOGY.**Prevention of Puerperal Septicæmia.**

DR. H. G. WETHERILL, (*Colorado Medical Journal*), says:—(1) When labor is about to begin, or as soon after as possible, one or more enemas of soap and water are to be given till the rectum is quite empty; then (2) the patient is to have a warm soap bath—in a bath tub if one be available—particular attention being given to the cleaning of the external genitals and anus and the creases and folds of the skin about the groins, abdomen, buttocks, and thighs. (3) The external genitals are then to be washed with a solution of bichloride of mercury 1:1000, or of lysol 1:100, to be followed by clean, warm, boiled water. (4) A clean, dry, absorbent occlusion pad is now to be applied to the vulva, and, when possible, this should have been sterilized. (5) Clean washable clothing may be put on the patient, and a clean, properly protected bed is to be made ready for her. (6) After the patient has been prepared she must not use the water closet when the bowels or bladder are evacuated, but should use a clean chamber vessel, or jar, or a bed-pan. (7) After each evacuation the external genitals must be cleansed as before (No. 3) and a fresh occlusion pad must be put on. (Vulva pads are best made of cotton and gauze, and should be made and handled with clean hands only, and placed in clean receptacles. They may be burned when soiled).

Diagnosis of Ectopic Pregnancy.

DR. J. F. BALDWIN (*Courier of Medicine*) says:—There are no pathognomonic symptom of tubal pregnancy, or of any other form of ectopic pregnancy. Usually, however, we find the following points: The patient gives a history of several years of sterility (many exceptions); she has missed a menstrual period, perhaps two of them (numerous exceptions); she has noticed some unusual pains in the pelvis, which she will probably describe as boring, griping, or colicky in character, these pains being situated usually in the region of an ovary; she has, perhaps, within a few days of the time of consulting her physician had a more or less irregular hæmorrhage: perhaps has discharged pieces of membrane which she supposed indicated an abortion, and consulted her physician with the idea that such is the case, owing to the hæmorrhage and the pain, and the suspicion of an existing pregnancy. Possibly, however, there has been no suspicion of a pregnancy, as the woman has accepted her sterility as incurable and has dismissed from her mind such a possibility.

Treatment of Abortion.

H. B. STEHMAN, in *Medicine*, states the following principles in treatment of abortion and its complications:—

1. The rendering of the vulva, vagina, and uterus aseptic, and as far as possible maintaining them in that condition.
2. Arresting hæmorrhage, either by the use of the tampon in the cervix or vagina, or by directly emptying the uterus.
3. In inevitable abortion, the ovum, or any part of the product of conception, should be removed as early as possible.
4. That intelligent curettage is invariably indicated whenever a vestige of placental decidua remains, or any suspicion of infection is evident, and that a bacteriologic differentiation is necessary, both from the standpoint of prognosis and treatment.
5. When circumscribed local infection is a complication, evacuate the pus as early as possible and by the shortest route.

Hysterectomy in Puerperal Fever.

JORFIDA reports two successful cases of total vaginal hysterectomy for puerperal infection. Out of the 85 cases hitherto recorded 22 have recovered; as far as the figures go, it seems that vaginal hysterectomy is more fatal than abdominal. The first case was that of a woman, aged 37, multiparous, who was prematurely (six months) confined on January 17th, 1899. On the third day she went to work in the fields and was seized with severe pain. She was admitted into hospital, January 27th, with diarrhoea, vomiting, severe pain and fever, and in a partially typhoid state. The uterus was soft and tender, and had hardly undergone any involution. Endouterine sublimate douches were given. On January 31st the uterus was curetted. As no improvement followed, total vaginal hysterectomy was performed on February 1st. The patient left the hospital completely cured on March 3rd, 1899, and when last seen (September 1899) was in the best of health. The adnexa, which were secondarily infected, were at the same time removed. The second case was similar to the above; the woman left the hospital cured forty-six days after the operation.—*Brit. Med. Jour.*

Prolapse in Elderly Women.

In 1896, two new procedures were shown as remedies for prolapse in elderly women. One by FÆRUD relieved the prolapse in non-menstruating women by drawing downward the uterus and stitching it to the vagina, the secretions being discharged through a new opening in the fundus. In the same year WORMSER published a procedure by P. MULLER, in which the prolapse was remedied by excision of the vagina and the inclusion of the uterus, and reported many cases thus treated with good results. STOCKER, fearing that hydrometra might develop in the uterus thus devoid of any external passage, devised a modification of the method adapted to elderly women who still menstruated. He reports the case of a patient, aged 52, describes the operation, the first step of which was to make a long incision in the left side of the vaginal portio. The edges of this wound were stitched with catgut, uniting the mucous membrane with that of the cervical canal. Then a strip of the vaginal mucous membrane on the left side, about 5 cm. broad, was allowed to remain, all the rest was removed and the denuded surfaces united with sutures, thus leaving a very small passage for the discharge of all secretions. This operation was quickly and easily performed, and the results very satisfactory.—*Phil. Med. Jour.*

Implantation after Injury of Ureter During Laparotomy.

N. FENOMENOFF relates, in a Russian journal quoted by the *Sov. Med.*, that he had the misfortune to excise a small portion of one ureter during a tedious operation for removal of cystic tumors in the broad ligament. Instead of suturing the ureter to the abdominal wound and ablating the kidney later, he resolved to excise the kidney at once, as *restitutio ad integrum* was impossible. He, therefore, drew the proximal stump of the ureter down as far as possible to prevent a diverticulum, and threw two ligatures around it, then replaced it in its normal position and sutured the abdominal wound, draining through the vagina. The patient made an uninterrupted recovery, complaining merely of a few dull pains at times in the lumbar region at first. She left the hospital in a month, and during the year since the operation has been in good health, with no indication of abnormal function even on analysis of the urine.

PHYSIOLOGY, PATHOLOGY, AND BACTERIOLOGY.

Theory of the Physiology of Spinal Anæsthesia.

H. H. STONER (*Medical News*) states that the term "medullary narcosis" is misleading, since it gives the impression that the injection is made into the substance of the cord, whereas in reality the solution is thrown into the subarachnoid cavity some distance below the termination of the spinal cord. The most plausible theory as to the way in which the poison gains access to the cell-bodies is that the axons, occupying the cavity into which the solution is thrown, absorb it and transfer it by way of their vascular supply back to the cell. It is noteworthy that the neurons most profoundly affected by the solution are those that go to make up the cauda equina. The motor neurons, the axons of which pass through the cauda equina, apparently go on performing their function of transmitting motor impulses unimpaired of the presence of the toxic agent. It must not be supposed that these neurons are unaffected by the solution. The cytological structure of their cells undergoes the same morbid change as do those of the sensory neurons, but owing to the direction of the motor current and the relation of the end plates of the peripheral motor neurons to the muscle fibres, their capacity for transmitting motor stimuli to their destination in the muscle is not seriously handicapped. Stimuli over the sensory tract are prevented from reaching their destination, owing to paralysis and withdrawal of the arborizing extremity of the peripheral sensory neuron from contact with its associated one, but in the case of the peripheral motor neuron no such effect takes place. The solution paralyses the arborizing processes of this collateral branch as well as those of the ascending branch, and such being the case, it is withdrawn from functional relation to the peripheral motor neuron, and reflex activities are thereby inhibited.

Bowel Lesion of Typhoid Fever.

Dr. T. J. MACLAGAN says:—"The points to be noted in connection with the bowel lesion are: (1) That the structure on which the typhoid bacillus exercises its specific effects are the solitary and agminated glands situated in the submucous coat of the small intestine. (2) That the change which it causes in these glands is inflammatory in nature and essentially consists in proliferation of their cellular and granular contents, with consequent swelling and hardening of the glands. (3) That this inflammation is generally sufficiently severe to cause gangrene and sloughing of the affected glands. (4) That the direct action of the typhoid bacillus is limited to the glands of the submucous coat, and that it has no direct action on the mucous, muscular, or peritoneal coats. (5) That the sloughing process that destroys the glands necessarily also destroys the mucous membrane situated over them. (6) That with the process of sloughing and suppuration there come into play other and new morbid agencies, the various forms of coöcal associated with these processes. (7) That to these new agencies, rather than to the typhoid bacillus, are to be attributed all the more serious complications and all the formidable symptoms, general as well as local, which are apt to show themselves during the third and fourth weeks of the disease."

Pathology of Hepatic Cirrhosis.

From a study of the tissue formation in cases of cirrhosis of the liver, FLAXMAN comes to the following conclusions: (1) In all forms of cirrhosis the white fibrous tissue is increased. (2) Along with the increase of white fibrous tissue there is a new formation of elastic tissue, which is derived from pre-existing tissue in the adventitia of blood vessels and the hepatic capsules. (3) Both white fibrous tissue and elastic tissue, in all forms of cirrhosis, may penetrate into the lobules. This penetration takes place along the line of capillary walls, or follows the architecture of the reticulum. The chief distinctions between the histology of atrophic and hypertrophic cirrhosis depend upon the degree of extralobular growth and the freedom with which the lobules are invaded. In hypertrophic cirrhosis there would appear to be less interlobular growth and an earlier and finer intralobular growth. (4) The alterations in the reticulum, *per se*, consist, as far as can be made out at present,

of hypertrophy rather than hyperplasia of the fibres. It is still uncertain whether any of the differential methods now in use suffice to distinguish between the reticulum and certain fibres derived from the white fibrous tissue of the periphery of the lobules.

Bacillus Coli Communis.

THERE are at the present time numerous workers who are devoting themselves to the special study of one or other of the great classes of bacteria. Some five years ago it was the fashion to multiply the number of the members of a group, giving to each individual member which showed cultural differences a distinct name, irrespective of the genus to which it belonged, the name only indicating the class. The investigation of cultural reactions and pleomorphism in its various aspects is no less keen at the present moment—it is even intensified—but the prevailing tendency is to recognise the existence of genera, with a prototype at the head, each genus being divided into species with their respective varieties. Chief among the genera is the great "colon group," the principal class of intestinal and extraintestinal bacteria. Standing first and foremost as prototype, partly by reason of its ubiquity, partly on account of its multifarious activities, is the *B. coli communis*, and following this in the same species is a lengthy list of coli-like organisms, while the other subdivisions of the group are the hog-cholera or GABRIEL species, the typhoid species, and lastly, the species of which the pneumo-bacillus of FRIEDLANDER may be taken as the type. Each of these species contains many varieties; even the typhoid group, of which the individual members show the least variation culturally, contains variants which the serum test differentiates. Dr. W. W. FORD, who is Fellow in Pathology of McGill University, has published a paper in the *Montreal Medical Journal*, at the end of which he has set out in tabular form a list of the cultural reactions of many members of the group. Though the various reactions enumerated do not exhaust the cultural distinctions which it is possible to obtain, yet a study of it, incomplete as it is, shows the importance of testing each organism in a variety of media and under differing circumstances with a completeness undreamt of twenty years ago, in order to identify the exact nature of the organism with which one is dealing. From the same author we have also lately received a paper embodying the result of some work on the bacterial content of healthy organs removed with due observance of aseptic precautions. His results are at variance with those of NEUMER and OPITZ, both of whom concluded, from the results of their experiments, that in the healthy animal a passage of bacteria through the intestinal wall does not take place. Dr. FORD obtained results of precisely opposite character, and this he attributes to the fact that his cultures were incubated for much longer periods than were used by either NEUMER or OPITZ, and were in most cases made in liquid media, which he considers a point of importance by reason of the dilution of animal bactericidal properties. As a result of a large number of experiments, he found that each species of animal possesses its own peculiar bacterial flora; whilst each animal, regardless of its species, showed its distinct bacteriology. Thirdly, the different organs of the various animals displayed the same bacteria on the different culture media. Fourthly, the condition of digestion exerted a decided, but not universal, influence on the species of bacteria found; and lastly, while many cultures remained sterile, there was ample microscopic evidence of bacterial activity within the organs inoculated into the culture medium.—*British Medical Journal*.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Hygiene of the Cyclist.

JUST LUCAS CHAMPIONNIERE states that cycling, like all exercise, should be taken up moderately. The heart should be carefully watched, not because this exercise is more harmful in this respect than others, but because it can be indulged in much longer without giving a sense of fatigue. Vicious attitudes, such as a crooked posture, although not being so important as is generally supposed, nevertheless ought to be avoided. In a long journey the position in which the body is moderately inclined is best for the organs of respiration and circulation. The position in the saddle is hard to decide upon for every case. Practice shows that the perineum accommodates itself to the saddle better than would have been supposed. Moderation in eating is a necessity in muscular work, as is also abstinence from alcohol. The bicycle should vary in details for the man, the woman, the child, the racer, and the invalid. In the case of a man, the perineum, with its component parts, should be carefully watched. As to the woman, this exercise is easier for her than for the man, since she is more supple. It causes far less fatigue than walking. Its effects on the pelvic organs are good. The exercise should be suspended during menstruation, and it is not to be recommended during pregnancy. The child does not feel so much fatigue as the adult, but it should use the bicycle with the greatest moderation. As a rider, the courier understands his limitations well. He should, like all athletes, possess perfect organs. As to the invalid, many ailments are improved or even cured by the use of the bicycle, e.g., gastro-intestinal troubles, deformities of the vertebral column, etc. Indeed, the author believes that this branch of the subject is so extensive as to deserve a special chapter.—*Gazette Médicale de Strasbourg.*

Banana Flour.

AMONG the thousands of intelligent men of various castes and creeds who live by the products of cocoanut and other plantations, it is curious that so little is heard of the manufacture of farina from the banana or plantain. The Colonial Institute of Marseilles, in reply to an inquiry made by the Colonial Office, gives some very interesting information on banana flour. This flour is used by the Creoles in Guiana, under the name of "conquénay," as food for invalids and infants. In the East Indies and the Malayan Archipelagoes it has been used for a long time past. In Central America, in Colombia and Venezuela banana flour is made on a vast scale and sent to the United States. Trials have been made, but without great success, in German West Africa and at Perak in the Peninsula of Malacca, in order to extend its preparation and importation into Europe. It is prepared in a very simple manner. The bananas are cut into round slices and put into a drying apparatus made of aluminium or silver. The banana flour, which is very nutritious, has been analysed by Dr. RHOMS, of Berlin University. It contains 1.455 per cent. of azotite, also 12.06 per cent. of starch, cane sugar 1.84, and tannin 6.53. A certain quantity is sent to England, where the price of 675 francs per ton of 2,240 English pounds is paid. Banana flour is certainly a production which has a future. The day may perhaps come when it will occupy the front rank in the food of the public.

The precautions used in drying the fruit are due to the readiness with which it takes a stain from metals when fresh. Sheet aluminium is now cheap enough in India to be used for lining iron pans of drying machines that may be made to pattern by any sheet iron worker, and heated with charcoal. Much of the drying might be done by the sun's heat, a fine net being put over the trays. The fibre of the plantain would be another source of revenue if separated from its juices by one of the many also fibre machines and well washed and dried. The industry may be started on the smallest scale and with the simplest appliances. Clean flat tiles would make an excellent drying floor; the darker the colour of the tiles, the hotter they will become in the sun. As the plantain requires rich soil for its full development, a sewage farm would offer the best prospects of success.

Action at Law on Food-Poisoning.

A CERTAIN Mr. SMITH and his wife brought an action against the Inns of Court Hotel, Ltd., London, to recover damage for injuries suffered by them. It appeared that 91 persons were dining one evening at the table d'hôte dinner at the above hotel on 17th of July of last year, of whom 39, including the plaintiffs, were more or less poisoned. They had all eaten either mutton or fish, and they were all poisoned by ptomaines. Two of the 39 had died. At the trial the jury gave a verdict for £140 damages. The defendants appealed, but the Court unanimously rejected the application. Lord Justice A. L. SMITH said: "If the case made out by plaintiffs in an action of negligence was equally consistent with the defendants having been guilty of negligence and with his having acted with due care, then there was no case to go to the jury. But in this case, where 39 persons out of 91 who partook of a particular meal were poisoned in a similar manner, he had to ask himself whether that state of facts was more consistent with there having been a proper examination of the food on the part of the persons who supplied it, or with there not having been a proper examination."

The learned Judge thought the state of facts was more consistent with there having been an improper examination; and Mr. Justice GRANTHAM had acted rightly in leaving the matter to the jury, and not accepting the suggestion of defendants' counsel that there was no case to go to the jury. He thought that seeing that the quantity of poison supplied in the food was large, it might have been detected had a reasonably careful examination been made. The jury had on the medical evidence reasonably found that there was a want of proper care. Both contentions for appellant failed, and the application for a new trial or verdict for defendants must be refused.

Food-poisoning is very common in India, not necessarily with fatal results, but it is sufficiently frequent to demand a regular inspection on the part of health authorities into the state of the kitchens of hotels, boarding houses, and railway refreshment rooms.—*The Indian Municipal Journal and Sanitary Record.*

Human and Other Mammalian Blood.

THE distinction between human blood and that of other mammals has been based upon the size of the red corpuscles, and it has been found that they have not been altogether reliable. A new method proposed by WALKER is based, first, on the morphologic and microchemic characters of the granules of the polymorphonuclear leucocytes; and second, on the ability to recognize these conditions in the dried blood. It is well known that leucocytes of the human blood contain granules that are brought out by special staining methods. Disregarding the "mastocells," these granules are of two kinds, differing in size and staining properties. About 97 per cent. of the polymorphonuclear leucocytes contain numerous, minute, irregular granules which stain in neither basic nor acid stain, but only with certain combination stains like EMBLION's "triacid," and are therefore called neutrophils. The remaining 3 per cent. contain large spherical uniform granules that stain only with the acid stains—acidophiles. Of the other mammals, apes are said to show neutrophils, but all other species contain only acidophiles and non-granuliferous leucocytes. He describes the condition in different animals, and gives a table showing the staining reactions of the granules in a number of species.

THERAPEUTICS & PHARMACOLOGY.

Intraspinal Injection of Cocaine.

THE success which has attended the intraspinal injection of cocaine for the purpose of producing analgesia of the lower part of the body led GORFE to use it in a case of abdominal hysterectomy which he believes is the first instance of the kind on record. The patient was a woman of 51, suffering from hemorrhages due to multiple fibroids. One-third of a grain of cocaine was injected in the third lumbar space; but as the analgesia was imperfect, 15 minutes later the needle was inserted in the second lumbar space, 22 drops of spinal fluid were allowed to escape and $\frac{1}{4}$ of a grain injected. Analgesia promptly appeared, reaching above the umbilicus. The operation occupied 40 minutes, and the recovery from the cocaine came so promptly that the last manipulations, the removal of sponges from the abdominal cavity and sewing of the wound, gave occasional twinges of pain. There was some nausea, vomiting, and headache afterward, the vomiting recurring on the second day. Aside from this the recovery was uneventful. GORFE says that what remote consequences may develop as the result of such interference with the spinal fluid as this method involves can only be determined after more prolonged observation; but up to the present time no detriment to patient has attended the procedure, although observations have extended over a period of two years.

Treatment of Pneumonia.

WALTON advises the avoidance of exposure to other cases, confining of the patient to bed, avoiding all unnecessary exertion of any kind, the use of white flannel clothing, one or more daily spongings with tepid water and vinegar, and a diet consisting of milk, soups, lemonade, etc. In a robust patient, at an early stage the lancet will sometimes cut short the disease, and a brisk purge and one or two large doses of quinine may be of value. The drug he most depends on is NONWOOD'S tincture of veratrum viride, 2 to 4 minims every two hours or oftener, watching its effect on the pulse and bringing it down to 70 or 80 and holding it there. He has never seen any untoward effects, and if the treatment fails to arrest the disease, it makes it milder and more easy to manage. If it goes into the second stage, give ammonium carbonate 5 grains every two hours as a stimulant and absorbent. Strychnia is the best stimulant and tonic we have, and should be used freely when indicated. Digitalis is of service when the pulse is weak and rapid. Transfusion of normal salt solution should be used in bad cases and opiates to relieve pain if necessary.—*Virginia Medical Semi-Monthly.*

Winslow's Soothing Syrup.

TAKE of—

Morphia sulph	$\frac{1}{2}$ gr.
Sodii carb	1 gr.
Simp. syrup	1 $\frac{1}{2}$ oz.
Aqua	$\frac{1}{2}$ oz.
Spirit feniculi	1 dr.

—New Idea.

For Pyrosis.

Two following pill is useful:—

R	Zinc oxid	2 $\frac{1}{2}$ grains.
	Powdered opium	$\frac{1}{2}$ grain.
	Extract of hyocyamus	2 grains.

M.

For Treatment of Corns.

R	Extract of cannabis indica	1
	Salicylic acid	10
	Oil of turpentine	5
	Glacial acetic acid	2
	Cocaine (alkaloidal)	2
	Collodion	q. s. ad. 100

M. Apply a thin coating every night, putting each coating on top of the preceding one, until finally the whole drops off, bringing the indurated portion, and frequently the whole corn, with it.

For Cerebral Congestion.

THE following has been highly recommended:—

R	Potassium bromide	3 drachms.
	Fluid extract of ergot	2 "
	Water	to 6 ounces.

M.

One tablespoonful to be taken three times daily. This mixture has been found serviceable as a prophylactic after severe head injuries.

Correspondence.

UNPOPULARITY OF THE MILITARY HOSPITAL
ASSISTANT CLASS OF THE SUBORDINATE
SERVICE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—There is a circular from the Principal Medical Officer, Bombay Command, inquiring from senior Hospital Assistants of the Bombay Presidency of causes which have made the subordinate branch of the Hospital Assistant class so very unpopular that, though there are some fifty vacancies at present in the service, no candidates are forthcoming to join it.

May I take this opportunity, through your valuable paper, to bring to the notice of the authorities that, so far as pay and prospects are concerned, there is very little difference between the Civil and the Military service of the Hospital Assistant class, except a senior Hospital Assistantship in the latter service on a salary of Rs. 100 per mensem, which could not be considered more remunerative, taking into account the inconveniences, difficulties, and dangers one has to encounter in the Military Department than his brother in the Civil one, who has more or less an easy life, free from bothers and dangers of battlefield, etc., and mostly passes his period of service in his own town or district.

Besides, Hospital Assistants in the Military Department have the same kind of duties and responsibilities in connection with native troops that Assistant Surgeons have in connection with British troops. Both these subordinate branches of the military service have the same collegiate course of study and the same dangers and difficulties to encounter in peace or war. Consequently, justice would demand that both branches should have equal pay and prospects. But, notwithstanding this, Assistant Surgeons are far more better paid than Hospital Assistants.

If the authorities are bent upon removing all grievances and dissatisfaction for good, and make the branch a really attractive one, I beg to suggest that status, leave, pension, promotions and allowances and other concessions of the Hospital Assistant class should be just on equal footing with that of the Assistant Surgeon class, and pay of the former in every grade, from top to bottom, may be 50 per cent. less than that of the latter, owing to crime of their color.

I think this is a just and fair demand, and I trust, as the authorities have now come to recognize that the Military Hospital Assistants have real grievances which have made the branch so very unpopular, your able pleading and support will shortly bear some good fruits.

Yours, &c.,
J. M. P.

SOMETHING MORE ABOUT CIVIL ASSISTANT SURGEONS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—Your issues of the 13th and 20th February contain "TOMTIT, M.B.'s" reply to "LIEUTENANT-COLONEL, I. M. S.," with regard to Civil Assistant Surgeons. Lord! hasn't the "little bird allowed himself to be drawn?"

It is naturally presumed that he defends the class from personal interest, and his advocacy is for "locally educated" men. He admits the superiority of *all* classes of medical men who obtain English diplomas, and pits the "locally educated" civil man against the military one who has not qualified in England. It is natural to assume also that the "little, TOMTIT" is a locally educated man too. Here is a man who, under the freedom of the English flag, has been educated for a nominal sum in one of the local colleges by I. M. S. officers, and who, on obtaining his *ead* (a local degree), turns on that Government, accusing it of "color blindness," "favouritism," and negligence in not "properly training" "native Assistant Surgeons! He has been so well drawn as to show the leper's skin under the thin veneer. His bitter opposition to Military Assistant Surgeons, his depreciation of them by comparison, his highly-exalted opinion of his own class, and the false ideas of Government and I. M. S. officers "being frightened by the very mention of a simultaneous I. M. S. examination," prove what is to be expected of men of his thought and class. He is quite right about there being "always two opinions" regarding the designation of military men as Assistant Surgeons; but it is always to be remembered that the value of an opinion depends upon its source. Government holds its own opinion, and "TOMTIT, M.B.," and men of his clique, hold theirs; but the issue of judgment does not lay with the latter, thank heaven!

"TOMTIT" wants his class to be Civil Surgeons of Districts and Superintendents of Jails. The former has been given to some of them, and his own admission is that some are unfit. They have been tried as Superintendents of Jails when having over ten years' service, and have proved failures.

It is a pity he has not gone in for an I. M. S. commission himself; if he did, we would have him complaining that he was not made an Inspector-General of Hospitals, or an Inspector-General of Prisons; that would be "color blindness" too and "favouritism." Government will "not allow Indian youths to compete for Military Assistant Surgeoncies," he says, because they are "feared." Great Scott!! would not I like to see "TOMTIT, M.B.," and others of his class, in a Military Station Hospital! Lord! would it not be fun to see them among the "Tommies!" There would be "fear" then, I am sure—tailor and shoemaker would soon meet, and there would be discipline! The fact is, Sir, Government has been too liberal in allowing natives to be educated to the extent that has been permitted, for we find that race feeling is not lost; most of them are too big for their shoes, and are the very ones who foster discontent, and surreptitiously stir up bad feeling between people who would otherwise remain on the most friendly terms.

"TOMTIT, M.B.," has made a lame defence for his class. He has admitted to be true all that "LIEUTENANT-COLONEL, I. M. S.," has said, and all he is doing now is to disturb the harmony that exists between the civil and military members of the Assistant Surgeon class. He is making it uncomfortable for those working together as "Civil Surgeon" and Assistant. As for his opinion of the military officer's work in civil employ, let the Inspector-General of Hospitals and the Director-General judge. The European public have theirs, and be sure it is not in favour of the Babu class.

Yours, &c.,
"METAMORPHOSIS APOTHECARY."

Government Medical Gazettes.

BENGAL.

Major R. H. Charles, M.D., F.R.C.S., I.M.S. (Bengal), Prof. of Surgical and Descriptive Anatomy in the Med. College, Calcutta, and *ex-officio* Surgn. to the College Hosp. is granted furlough out of India on med. certificate for eight months from the 20th Feb. 1901.

Major D. M. Mohr, M.D., I. M. S. (Bengal), Offg. Civil Surgn., Chittagong, is apptd. to officiate as Prof. of Surgical and Descriptive Anatomy in the Med. College, Calcutta, and *ex-officio* Surgn. to the College Hosp., during the absence, on furlough, on med. certificate, of Major R. H. Charles, M.D., F.R.C.S., I. M. S. (Bengal), or until further orders.

The services of Capt. A. W. E. Cochrane, M.D., F.R.C.S., I. M. S. (Bengal), are placed temply. at the disposal of the Govt. of the Punjab.

Asst. Surgn. Syed Mahomed Afzal did duty at the Med. College Hosp., Calcutta, from the 21st to the 26th Jan. 1901.

Asst. Surgn. Dino Nath Mitter, Teacher of Anatomy in the Campbell Med. School, is allowed privilege leave for three months from the 26th Jan. 1901.

Asst. Surgn. Jyotish Chandra Mustaf, Addnl. Demonstrator of Anatomy, Med. Coll., Calcutta, is apptd. to act as Teacher of Anatomy in the Campbell Med. School, from

the 26th Jan. 1901, during the absence, on leave, of Asst. Surgn. Dine Nath Mitter.

Asst. Surgn. Syed Mohamed Afzal is apptd. to act as an Addnl. Demonstrator of Anatomy, Med. Coll., Calcutta, from the 26th Jan. 1901, during the absence, on deputation, of Asst. Surgn. Jyotish Chandra Mustafi.

Asst. Surgn. Basanta Kumar Roy is allowed leave for four months, on med. certificate, from the 26th Nov. 1900.

The Lieut.-Governor is pleased to appoint Mr. C. Morris to be a visitor of the European Lunatic Asylum at Bhawanipur, vice Mr. H. P. Newton.

Mily. Asst. Surgn. W. Sherrington did duty at the Presidency Gen. Hosp. from the 25th Nov. 1900 to the 29th Jan. 1901.

Senior Asst. Surgn. Nobin Chunder Dutt made over ch. of the Noakhali Jail to Asst. Surgn. U. N. Sen, Rai Bahader, on the 5th Feb. 1901.

Capt. W. W. Clemens made over ch. of the Ranchi Jail to Capt. E. S. Parry on the 16th Jan. 1901.

Babu Mohendra Chunder Moumunder made over ch. of the Bogra Jail to Asst. Surgn. Sarat Chandra Sen on the 2nd Feb. 1901.

Capt. J. T. Calvert, I.M.S., made over ch. of the Darbhanga Jail to Lieut.-Col. T. Grainger, I.M.S., on the 2nd Feb. 1901.

The following Civil Hosp. Assts. passed the medico-legal exam. of Med. Sub. on the dates specified against their names:—

Mir Abdul Bari; Soshi Bhusan Roy; Sarat Chandra Sen; Shaik Mahomed Ibrahim; Kamini Kumar Sen; Amrita Lal Mandal; 31st Jan. 1901. Man Mohun Chakravarti; Pryn Nath Roy; 1st Feb. 1901.

Asst. Surgn. Syed Hasam held ch. of the Sumbhu Nath Pandit Hosp. at Bhowanipore from the 31st Dec. 1900 to the 11th Jan. 1901.

Asst. Surgn. Bhagabutty Kumar Chowdhuri, in offg. ch. of the Sumbhu Nath Pandit Hosp. at Bhowanipore, is allowed privilege leave for three months, from the 31st Dec. 1900.

Asst. Surgn. Hari Pada Mukerjee, Inspector in ch. of Animal Vaccination Depot, Calcutta, is apptd. to act at the Sumbhu Nath Pandit Hosp. at Bhowanipore, from the 13th Jan. 1901, during the absence, on leave, of Asst. Surgn. Bhagabutty Kumar Chowdhuri.

Asst. Surgn. Syed Hasam is apptd. to act as an Inspector in ch. of the Animal Vaccination Depot, Calcutta, from the 19th Jan. 1901 during the absence, on deputation, of Asst. Surgn. Hari Pada Mukerjee.

Asst. Surgn. Harendra Kumar Das, on return from leave, is apptd. to do suppy. duty at the Med. Off. Hosp., Calcutta.

Asst. Surgn. Brojendra Nath Basu, who was tempy. employed in Bengal, is permanently admitted into the service of Govt. as an Asst. Surgn. from the 2nd Jan. 1901.

Asst. Surgn. Amulya Chandra Champati, of the Krishnagar Disty., held med. ch. of the civil em. of Nadia from the 24th Aug. to the 1st Nov. 1900 in addn. to his own duties.

Mily. Asst. Surgn. T. H. Bonnar, in ch. of the Chausa Plague Camp, is allowed privilege leave for two months from the 26th Jan. 1901.

BOMBAY.

The following transfers are sanctioned:—

Mily. Asst. Surgn. Hugh Alexander Poyntz, I.S.M.D., from under the orders of the Health Officer of the Port of Bombay, to Sir J. J. Hosp., Bombay.

Mily. Asst. Surgn. R. W. Chittu, I.S.M.D., from Sir J. J. Hosp., Bombay, to Mily. Dept.

Hosp. Asst. Aldas Wadhmal, from Cholera duty, Thar and Parkar Dist., to Gen. duty, Hyderabad.

Hosp. Asst. Belchand Jawharmal, from Cholera duty, Lyari, Karachi, to Gen. duty, Hyderabad.

Hosp. Asst. Jethmal Manikrai, from Gen. duty, Hyderabad, to Gen. duty, Shikarpur.

Hosp. Asst. Hukumatrai Asanand, from Poor House, Umarkote, to Gen. duty, Hyderabad.

Mily. Asst. Surgn. Vinayal Hamsand, from N.W. Ry. Hosp., Kotri, to Rohri-Kotri Ry. Disty., Rohri.

Hosp. Asst. Choithram Pessensing, from N.W. Ry. Hosp., Kotri, to Gen. duty, Jacobabad.

Hosp. Asst. Choithram Shewatam, from Rohri-Kotri Ry. Disty., Rohri, to N.W. Ry. Hosp., Kotri.

Hosp. Asst. Lekhray Lalchand, from Cholera duty, Thar and Parkar Dist., to Cholera duty, Lyari, Karachi.

Hosp. Asst. Vithoba Mathurajee, from Cholera duty, Kotri, to Cholera duty, Karachi.

Hosp. Asst. Mohomed Rahimankhan, from Famine duty, Thar and Parkar, to Matsai Disty.

Hosp. Asst. Bharsing Tewaring, from Matsai Disty. to Commr. in Sind's Estab.

Hosp. Asst. Bulchand Jawharmal, from Gen. duty, Hyderabad, to Koti Bunder Disty.

Hosp. Asst. Hekumatrai Asanand, from Gen. duty, Hyderabad, to Central Prison Hosp., Hyderabad.

Hosp. Asst. Gobindram Utamchand, from Central Prison Hosp., Hyderabad, to Gen. duty, Shikarpur.

Hosp. Asst. Khalikdad Khudadadkhan, from Cholera duty, Jacobabad Taluka, to Kashmir Disty.

Hosp. Asst. Alimahomed Hussainkhan, from N.W. Ry. Hosp., Kotri, to Sind Gang.

Hosp. Asst. Lal Mahomed Futeh Mahomed, from Sind Gang, to N.W. Ry. Hosp., Kotri.

Hosp. Asst. Liharam Utamchand, from Gashi Yasinia Disty., to Gen. duty, Sukkur.

Hosp. Asst. Lekhray Lalchand, from Cholera duty, Karachi, to Masora Disty.

Hosp. Asst. Bhasker Shripur, from Gen. duty, Nasik, to Famine duty, Waghad.

Hosp. Asst. Kavasji Ramani, from Gen. duty, Ahmedabad, to Civil Hosp., Kaira.

Hosp. Asst. Waman Ambaji Warty, from Roman Catholic Orphanage School, Poona, to Civil Hosp., Sholapur.

Hosp. Asst. Munjanath Timappa, from Gen. duty, Poona, to Civil Hosp., Ahmednagar.

Hosp. Asst. Bhimaji Krishna, from Famine duty under the orders of the Sany. Commr. for the Govt. of Bombay, to Disty., Navalgand.

BURMA.

Hosp. Asst. H. C. Koyal relinquished ch. at the Outpost Hosp., Wundwin, Shamo dist., on the 14th Jan. 1901, and assumed ch. at the Police Hosp., Shamo, on the 16th Jan. 1901.

Hosp. Asst. H. C. Koyal relinquished ch. at the Police Hosp., Bhamo, on the 19th Jan. 1901, and assumed ch. at the Civil Hosp., Bhamo, on the same day.

Hosp. Asst. Sawan Singh relinquished ch. of his duties with the Milly. Police detachment at Bampton, Southern Shan States, on the 31st Dec. 1900, and assumed ch. at the Civil Disp., Bampton, Southern Shan States, on the 1st Jan. 1901.

Hosp. Asst. Sawan Singh assumed ch. of additional duties at the Police Hosp., Bampton, Southern Shan States, on the 1st Jan. 1901.

Hosp. Asst. P. Govindoo Pillay, on return from Akyab after the deptl. exam., held ch. of supy. duties at the Civil Hosp., Sandoway, from the 10th to the 29th Nov. 1900.

Hosp. Asst. Obowdhuri Sherafuddin, on return from leave, assumed ch. at the Gen. Hosp., Rangoon, on the 16th Dec. 1900, as a supy.

Hosp. Asst. Obowdhuri Sherafuddin relinquished ch. at the Gen. Hosp., Rangoon, on the 31st Dec. 1900, and assumed ch. at the Police Hosp., Lashio, Northern Shan States, on the 5th Jan. 1901, as a supy.

Hosp. Asst. D. Phillip relinquished ch. at the Civil Hosp., Shwegyin, Toungoo dist., on the 19th Dec. 1900, and was attached on supy. duty to the Gen. Hosp., Rangoon, on the 27th Dec. 1900.

Hosp. Asst. D. Phillip relinquished ch. of supy. duties on 27th Dec. 1900, and assumed ch. as Deputy Superintendent, Lunatic Asylum, Rangoon, on the 31st Dec. 1900.

N.-W. P. & OUDH.

Civil Asst. Surgn. E. Millican, attached to Sadr Disp., Bara Banki, extraordinary leave without allowances for one year from the date he may avail himself of it.

Tempy. Civil Asst. Surgn. Kasbi Nath, on being relieved of plague duty in connection with Magh Mela, Allahabad, to reserve duty at Benares.

Civil Hosp. Asst. Narain Pershad, on reserve duty at Lucknow, to the ch. of the Hussainabad Disp., as a tempy. measure, vice Asst. Surgn. Rusehid-ud-din.

Civil Asst. Surgn. Purna Chandra Mukerji, attached to Nagina Disp., in the Binjor dist., to plague duty at Ballia.

Hosp. Asst. Faraghat Ali Shah, from reserve duty, Lucknow, to the ch. of Nagina Disp., in the Binjor dist., as a tempy. measure.

The services of Civil Asst. Surgn. Rashid-ud-din, in ch. of the Hussainabad Dispensary, Lucknow, are tempy. placed at the disposal of the Rampur State, from the 1st Feb. 1901.

Milly. Asst. Surgn. W. Heathcock, in civil med. ch. of Unao, was on leave on med. certificate from the 16th Nov. to the 21st Dec. 1900.

Lieut. C. W. Mainprize, R.A.M.C., to the civil med. ch. of the Farrukhabad dist., in addn. to his milly. duties, from the 4th Feb. 1901.

Maj. D. W. Scotland, I.M.S., Civil Surgn., Etawah, is placed on special duty in connection with plague in Benares.

Capt. J. M. Crawford, I. M. S., whose services have been replaced at the disposal of this Govt. by the Govt. of India, Home Dept., to be Civil Surgn., Etawah.

Civil Asst. Surgn. Gobind Chandra Banarji, attached to the Sadr Disp., Unao, held ch. of the civil med. duties of that dist., in addn. to his other duties, from the 16th Nov. to the 31st Dec. 1900.

CENTRAL PROVINCES.

One month's leave on med. certificate is granted to Civil Hosp. Asst. Muhammad Aftab-ud-din, on gen. duty at Chanda, from the date on which he is permitted to avail himself of it.

Civil Hosp. Asst. Rajoni Kanta Sahai, on gen. duty at Hoshangabad, is granted two months' leave without pay from the 17th Jan. 1901.

Civil Hosp. Asst. Sajjad Hussain, of the N.-W. P. Estab., was, on reversion from famine duty in the Civil Dept., on gen. duty at Bhandara from the 8th to the 15th Nov. 1900.

Civil Hosp. Asst. Ramchandra Sitaram, on gen. duty at Jabulpore, is tempy. apptd. to the Pandhara Branch Disp., in the Nagpur Dist.

Civil Hosp. Asst. Vithal Anand Rao, attached to the Pandhara Branch Disp., is granted privilege leave for two months from the date of relief by Ramchandra Sitaram.

On reversion from famine duty under the P. W. D., Native Doctor Wali Ullah of the N.-W. P. Estab. was placed on gen. duty at Jabulpore from the 16th to the 31st Oct. 1900.

Civil Hosp. Asst. Budhu Lal, on gen. duty at Hoshangabad, is deputed on plague duty at Itarsi, in the Hoshangabad Dist.

PUNJAB.

Lieut. G. Browne, I. M. S., assumed ch. of the Civil Med. duties of the Kohat Dist. on the 31st of Jan. 1901, relieving Capt. V. G. Drake-Brockman, I. M. S.

Capt. C. N. C. Wimberley, I. M. S., assumed ch. of the Civil Med. duties of Mardan on the 7th of Feb. 1901, relieving Capt. A. W. B. Cochrane, I. M. S.

Lieut. E. D. W. Greig, I. M. S., assumed ch. of the Civil Med. duties of Mardan on the 8th Feb. 1901, relieving Capt. C. N. C. Wimberley, I. M. S.

Capt. A. W. B. Cochrane, I. M. S., whose services have been placed tempy. at the disposal of the Govt. of the Punjab, is apptd. to officiate as Supdt. of the Punjab Lunatic Asylum, from the 11th of Feb. 1901, vice Capt. G. F. W. Ewens, I. M. S., proceeding on leave.

Lieut. J. T. Weston, Civil Surgeon, Hissar, is transf'd. to Gujranwala, where he assumed ch. of his duties on the 6th of Feb. 1901, relieving Capt. J. Davis.

Capt. J. Davis, Civil Surgeon, Gujranwala, is transf'd. to Hissar, where he assumed ch. of his duties on the 9th Feb. 1901, relieving Asst. Surgn. Brij Lal, Hissar Disp., who acted as Civil Surgn. of Hissar, in addn. to his other duties, from the 1st to the 9th Feb. 1901.

Capt. V. G. Drake-Brockman, I. M. S., made over ch. of the duties of Supdt. of the Kohat Jail to Lieut. G. Browne, I. M. S., on the 31st Jan. 1901.

Lieut. J. T. Weston, M. D., Senior Asst. Surgn., made over ch. of the duties of Supdt. of the Hissar Jail to Kawaja Tasadduq Hussain, B. A., Extra Assistant Commr., on the 1st Feb. 1901.

Hosp. Asst. Ganesh Datta, doing gen. duty at Dera Ismail Khan, is transferred to Delhi for gen. duty from the 23rd Jan. 1901.

Hosp. Asst. Ghazi ud-din, Dalhousie Disp., has obtained three months' privilege leave from the 5th Feb. 1901.

Hosp. Asst. Fattah Singh, Police and Civil Stn. Hosps., Delhi, has obtained three months' privilege leave, and was relieved of his duties on the 4th Feb. 1901 by Hosp. Asst. Ganesh Datta, doing gen. duty at Delhi.

Hosp. Asst. Bindraban, doing gen. duty at Hoshiarpur, was apptd. to the Nowshera Dargal Section of the N.-W. Ry. on the 2nd. Feb. 1901.

Asst. Surgn. Feroze ud-din, Civil Hosp., Umballa, is transferred to the Jullundur Dist. for plague duty. He reported himself to the Plague Med. Offr., Banga, on the 1st Feb. 1901.

Hosp. Asst. Khuda Baksh, on plague duty, Jullundur Dist., is transferred to the Sialkot and Gurdaspur Dist. for plague duty. He reported himself to the Plague Med. Offr. on the 10th Feb. 1901.

Hosp. Asst. Ishar Das, doing gen. duty at Jullundur, was apptd. to the Jullundur Jail Hosp. on the 9th Feb. 1901, relieving Hosp. Asst. Chanan Shah, retired.

Senior Asst. Surgn. Bal Sahab Bhagwan Das, Gurdaspur Civil Hosp., has obtained one month's privilege leave from the 3rd Feb. 1901.

Tempy. Asst. Surgn. Jagat Narain, doing gen. duty at Sialkot, is transferred to Gurdaspur for tempy. ch. of the Civil Hosp., from the 8th Feb. 1901.

Asst. Surgn. Kirpa Ram, Kora, Fazlika Disp., Ferozepore Dist., obtained privilege leave from the 1st to the 21st Jan. 1901.

Asst. Surgn. Kirpa Ram, Kora, was apptd. to do gen. duty at the Mayo Hosp., Lahore, on the 21st Jan. 1901.

MARRIAGE.

CUNNINGHAM—SKINNER.—At St. James's Church, Delhi, on the 18th February, by the Rev. P. C. Nugent, Chaplain, Major J. A. Cunningham, I.M.S., Civil Surgeon, Delhi, to Mabel, widow of the late A. E. Skinner, Esq., and daughter of E. A. Poole, Esq., of Sussex House, Brighton.

ORIGINAL ARTICLES.

SURGERY OF THE KIDNEY: A RECORD OF TWENTY-TWO CASES.

BY JOSEPH L. BREESTON, L.R.C.S.P., L.R.C.S.I., ETC.,
Newcastle.

THE following is a list of cases of renal surgery which have come under my care, mostly in the Newcastle Hospital. Classified, they are as follows:—

Nephrolithotomy	12
Nephrectomy	3
Nephrotomy	2
Nephrorrhaphy	2
Perinephric Abscess	2

CASE I.—Perinephric Abscess.—A. T., sailor, aged 24, admitted January 1888. Had enteric fever and was discharged from hospital two months ago. Says that he has never been strong since. Has complained of more or less pain in right side; very emaciated, and has night sweats; urine alkaline and contains pus cells. Large, tender, fluctuating mass in right lumbar region, extending from twelfth rib to crest of ilium.

Operation.—Oblique incision from just before the last rib forwards towards the iliac crest. The abscess was found comparatively superficial. The cavity was well washed out, and the kidney examined by palpation with the fingers. As it appeared healthy, a drainage tube was placed behind it, and the wound closed with silver-wire sutures. A wet compress of carbolic lotion was placed over the wound, and the cavity syringed twice daily with the same fluid. The man made an uninterrupted recovery, and was discharged in a month with the wound healed.

It would be well here perhaps to draw your attention to the period at which this operation was performed. At that time surgical procedures were not carried out with that attention to details which we are accustomed to observe now-a-days. Still I am bound to say that the case did well, though his recovery was rather more protracted than it would be under present conditions.

CASE II.—Calculus in Kidney.—H. A., aged 26, sailor, admitted January 1893. Has suffered from renal colic for three years; attacks varying in intensity, and generally, but not always, followed by blood in the urine; pain most persistent in the right testicle; urine contains crystals of lithic acid and some pus cells, is variable in quantity, very scanty during attacks of pain, deep pressure over the right kidney causes pain which radiates down to testicle of same side.

The symptoms pointing to a case of renal calculus, I operated by the oblique incision in the right loin. Some trouble was experienced in reaching the kidney, owing to the large amount of fat. At last the organ was exposed, and I proceeded to pass a darning needle through the convexity towards the pelvis. At the second puncture I was greatly relieved to feel the point of the needle grate against the stone. I now passed a tenotomy knife through the substance of the kidney beside the needle, until I felt it impinge upon the stone. A pair of sinus forceps followed and the stone was extracted. It was

composed of lithic acid and weighed only 20 grains. The wound in the kidney was washed out with boracic lotion, and ceased bleeding after digital pressure for a few minutes. A drainage tube was passed into the lower angle of the wound behind the kidney, and the external wound closed with catgut sutures. Blood was present in the urine for three days. After that the man had not a bad symptom. Looking back on this case in the light of subsequent experience, the stone was found, I think, easier than on any other occasion, and this with the needle, a method of procedure the more I use it the less I rely on it. The largest stone I have removed could not be detected by the needle. Still, by a lucky chance—for it was a chance, considering the size of the stone—I found it at the second puncture.

CASE III.—Pyonephrosis Nephrotomy.—J. H., aged 35, miner, Wallsend, has suffered from stricture for some years, necessitating the passage of catheters. Has had retention on two occasions. Urine has been purulent for some time. A fortnight since had rigors, and at same time seized with severe pain in left side. Is now very emaciated, with hectic at night. A mass can be felt in left lumbar region, extending to median line in front, and to level of umbilicus below. Urine alkaline; sp. g. 1015. About one-third pus on standing. Contains pus cells and a few blood cells. The kidney was exposed on the 18th July 1894 through the lumbar incision, and found to be enlarged to about three times the ordinary size. Digital palpation revealed fluctuation everywhere, but no hard substance. An incision was made through the cortex, and a large quantity of foul-smelling pus and urine evacuated. The kidney was well irrigated with boroglyceride, and a drainage tube placed in the kidney. The discharge was very profuse and lasted for about two months, leaving a sinus, which remained for twelve months. At the end of this time he left the district and I lost sight of him. I think now that the better course would have been to have excised the kidney.

CASE IV.—Perinephritic Abscess.—J. P., aged 40, labourer, Newcastle. A month ago began to feel ill. Reported himself with a "lump" in the side. Large, tender, fluctuating mass can be felt over right kidney, which, on being explored with needle, is found to contain pus. Urine normal. The kidney was exposed, and during the procedure an immense quantity of pus was evacuated. As the kidney appeared normal, the wound was irrigated and drained. The man was about again in a fortnight.

CASE V.—Nephrolithotomy.—M. B., aged 40, nurse, Newcastle, has been in failing health for four years. More or less pain in right side. Urine variable in quantity. Renal colic severe at times, followed by hæmaturia. Jolting in a vehicle induced the attacks and increased the amount of hæmaturia. Examination revealed a spot tender on deep pressure over right kidney. Urine alkaline, contains pus and blood cells; sp. g. 1015. The kidney was exposed by the oblique incision and brought up into the wound. Acupuncture detected the stone, after which the kidney was incised, and the stone extracted with forceps. Stone weighed 40 grains and was composed of lithic acid. Drainage tube was placed behind the kidney, the muscles united with catgut, and skin with silk worm gut.

She went on well for ten days, when the temperature began to rise, and thinking there was some collection of pus in the wound, I again cut down, but found everything normal. After this she progressed favourably, and left the institution in a month's time.

CASE VI.—Nephrolithotomy for Soft Calculus.—A. R., aged 32, married woman, Newcastle. Has had periodical attacks of renal colic, with hæmaturic pain always on right side, and always followed by discharge of lithic acid. Is emaciated and looks ill; urine acid, sp. g. 1020; crystals of lithic acid in abundance; has tender spot on right kidney; no tenderness in opposite side.

6th August 1895.—Kidney exposed and brought into wound. Acupuncture gave negative results, so I incised the cortex and passed the index-finger into the pelvis. This was lined with gritty substance, resembling that passed in the urine; no hard calculus was found. The kidney was well irrigated, and the wound closed in the usual manner. She was well in a fortnight, and has never had any attack since.

CASE VII.—Nephrolithotomy.—W. P., aged 22, horse-driver, Newcastle. Two years ago had pelvis fractured through being crushed underneath a waggon. Since then has always had urinary trouble; occasionally retention. I had already crushed a stone in his bladder six months previously. Urine never properly cleared up; always contained pus and phosphates in great quantity. Now has constant pain in right side, but no definite attack of renal colic, nor hæmaturia. Has very tender spot over right kidney.

Operated 7th August 1899.—Kidney exposed and brought outside loin. Palpation revealed stone at upper part of pelvis. I cut through the kidney substance on to the stone and extracted it with my finger. It weighed 60 grains and was phosphatic. He recovered from the operation, but died about twelve months afterwards from uræmia. At the *post-mortem* both kidneys were in the condition known as surgical kidney.

CASE VIII.—Nephrolithotomy.—M. R., aged 24, married woman, Lambton. For past three years has suffered from renal colic at frequent intervals, lasting for about an hour at a time. Attacks brought on by muscular efforts. Has only had hæmaturia once. Has tender spot over left kidney. Urine acid and contains a few blood cells; sp. g. 1028.

Operated 8th September 1895.—Kidney exposed by oblique incision and brought on to loin. Stone could be felt in the upper part of the ureter. I pushed it back into the pelvis. Made an opening through the kidney substance and extracted the stone with a sinus forceps. The kidney was replaced, the wound drained, and closed with silkworm gut. She had no further symptoms and went home in three weeks.

CASE IX.—Perinephritic Abscess.—L. S., aged 10, Newcastle. A weak, delicate-looking boy. Has suffered from hip disease for three years, but has been well for twelve months. Three months since had pain in left side, which has been constant more or less since. Now has swelling extending as far forward as nipple line on left side, and fluctuating. Urine contains pus cells; sp. g. 1010. Incision made 9th October 1895 over left

kidney, and after deep incision a cupful of foul-smelling pus was evacuated. Kidney palpated, but nothing abnormal was perceptible. The wound was packed with gauze and discharged for about a month. It healed completely two months later.

CASE X.—Pyonephrosis Nephrotomy.—E. J., aged 40, sailor. Has suffered for last four years from pain in left lumbar region. Attacks simulating renal colic, after which urine would be almost wholly composed of pus. Patient anæmic and emaciated. A tumour can be felt on left side of abdomen. More perceptible on pressure from behind. Is more or less tender all over this region, but no defined spot. Urine contains quantities of pus. Has hectic at night.

6th July 1896.—Incision made in lumbar region. Kidney cut down upon and found about three times the ordinary size and fluctuating. Incision made through cortex, and large quantity of pus and urine evacuated. No stone could be felt. Drainage tube placed in kidney and the wound packed. He made slow recovery, and was discharged four months later with a sinus in the loin. I have since lost sight of him.

CASE XI.—Nephrotomy for Calculus.—M. B., aged 50, engineer, Cooranbong. Healthy-looking man, florid complexion, has suffered from renal colic for some years; hæmaturia on two occasions; each attack of colic would be succeeded by a deposit of lithic acid in the urine. Jolting induced the attacks.

Is in good condition. Urine acid, contains lithic acid crystals; no pus cells; sp. g. 1025. Has tender spot over left kidney, producing sharp lancinating pain when pressed.

Left kidney exposed and brought out on to loin—needled all over with negative result. I then incised with scalpel and passed in my finger, then continued the incision nearly the whole length of the organ without finding any stone. Hæmorrhage was free, so the kidney was stitched with four deep catgut sutures, drainage tube placed behind the kidney and the wound closed. His recovery was uninterrupted.

Six months afterwards he called on me, stating that he had just recovered from a violent attack of renal colic, the first since the operation, and that afterwards he had passed a stone which he showed me. It was composed of lithic acid and weighed 25 grains. There was considerable difficulty in passing it through the meatus urinarius.

This case illustrates the difficulty sometimes met with in finding a stone in the kidney. The symptoms all pointed to its being there; but, even though the kidney was almost divided into two parts, I failed to find the stone.

CASE XII.—Lumbar Nephrectomy for Renal Tuberculosis.—E. M., aged 13, school-girl, Adamstown. Six months ago began to lose strength, and complained of pains in the back, on the region of the left kidney. Has steadily become worse; hectic, loss of weight, with rigors; is very thin and emaciated; tumour can be felt in left loin; very tender on pressure; urine contains pus and blood-cells, with some phosphates.

Kidney exposed by lumbar incision; about twice natural size. Nothing hard could be felt, but seemed solid nodular masses. On incision, foul-smelling pus and urine, with pockets of cheesy material, escaped. The whole kidney was one mass of these pockets, leaving no kidney substances. The ureter was blocked by a small phosphatic calculus. As it was apparent this kidney was not secreting urine, I removed it, first ligaturing off the ureter and vessels in separate ligatures.

Drainage tube placed in and left there for forty-eight hours.

There was absolutely no shock. The child expressed herself next morning as being perfectly well. She was discharged in three weeks.

CASE XIII.—*Nephrolithotomy*.—A. T., aged 23, cabinet-maker, Wickham. Suffered for three years from "pain in the back," for which he had tried various liniments. On close enquiry, this "pain" appeared to have a renal origin. There was no hæmaturia, but exercise and jolting always increased the severity of the pain of the attack. The chief diagnostic point was the extremely tender spot over the left kidney. The urine did not show any abnormality.

12th February 1897.—Kidney exposed by oblique lumbar incision and brought out. The needle was used freely without detecting any stone. I then incised the kidney, passed my finger into the wound, and found a small stone weighing 28 grains in one of the calyces. The subsequent history was uneventful, and three months later he had gained a stone and a half in weight.

CASE XIV.—*Nephrolithotomy*.—D. S. aged 18, school-girl, Uralla. This case is what one might call a surgical disaster. She was a girl of healthy appearance, but suffered from attacks of renal colic without hæmaturia; in fact the history was on all-fours with the previous case, the diagnostic point being the tender point on pressure over the left kidney. There was no difficulty in exposing and exploring the kidney. The hæmorrhage was a little free, but ceased on pressure. The wound was closed in the ordinary manner, and late at night she was fairly comfortable. Early the next morning she expressed a wish for a cup of tea, and a quarter of an hour later she was dead. There appears to be no assignable cause beyond a thrombus. This is the only case of the kind I have met with, and unfortunately there was no *post-mortem* obtained.

CASE XVI.—*Hydronephrosis, Abdominal Nephrectomy*.—L. W., aged 24, sempstress, Wickham. On the 3rd June 1897 was consulted by this patient, who had a "lump in her side." On examination there appeared a distinct swelling on the right side below the ribs and perceptible in the loin. Palpation with both hands showed a tumour, and percussion revealed the colon in front. There was no emaciation and no jaundice. Dulness of erector spina behind and almost to crest of ilium. Urine nothing abnormal, excepting at times she would pass an excessive quantity. Sp. g. 1028.

I decided to do nephrectomy by the abdominal method in consequence of the size of the tumour, and accordingly made an incision in the right linea semi-lunaris, about five inches in length. After opening the peritoneum, the tumour came into view with the colon toward the middle line. I pushed this further over and tore through the meso colon with my finger, freed the tumour down to the pedicle.

The posterior attachments were dealt with in the same manner, and the pedicle isolated with the vena cava at the bottom of the wound.

The pedicle was now transected with a double silk ligature and tied. Sponges were then packed round and the pedicle cut. A little oozing took place from the sides and bottom of the wound, but ceased after flushing with hot boracic lotion. The wound was closed in the usual manner. Very little shock was experienced, and she made an uneventful recovery, leaving hospital a month later.

CASE XVI.—*Nephrectomy, Renal Tuberculosis*.—L. B., aged 30. Three years ago began to suffer from frequency of micturition and odor urina. Is unmarried, but had a child eighteen months ago, which only lived for a week.

Six months prior to the operation I saw her. She was then losing flesh, with hectic and pyuria. There was a tender swelling, about the size of a closed fist, in the region of the left kidney; resonant in front.

I then recommended nephrectomy, but she preferred to wait.

Six months later she sent for me, and wished the operation performed at any cost. Her condition at this time almost precluded operative interference; but in consequence of the urgent entreaties of herself and friends, I consented to try what could be done, after explaining that it was almost hopeless.

On the 15th August 1897 I opened the abdomen over the most prominent part of the tumour, and enucleated it, forming a pedicle with the vessels and ureter. The latter was very much thickened and full of tuberculous deposit. After detaching it from the kidney I brought the end out through an opening in the loin.

Very little hæmorrhage occurred, but the shock was considerable. She remained in a collapsed state and died thirty-six hours later, only four ounces of urine being secreted since the operation. No *post-mortem* could be obtained.

CASE XVII.—*Moveable Kidney*.—M. D., aged 28, married, Wallsend. Three children. Has suffered from dragging pain in back and right loin for four or five years. Pain periodical in attacks, accompanied by nausea and vomiting, and rendered worse by exertion. In semi-prone position a moveable tumour can be made out, in size and shape similar to the kidney. Urine contains nothing abnormal.

Operation, July 1898.—Kidney exposed in the usual manner. The peri-renal fat separated by blunt dissection. Three catgut sutures were then passed through the substance of the kidney, then through either side of transverse fascia and muscles. The wound was then united with deep silkworm sutures, no drainage tube being used. She was kept in bed three weeks, and

discharged in a month. Twelve months afterwards she had not had any return of the old symptoms.

CASE XVIII.—Nephrolithotomy.—L. W., aged 22, domestic servant, Boggabri. Has had attacks of renal colic for four years, followed by hæmaturia. Pain increased by jolting in a coach. Physical signs not very marked, with the exception of an exquisitely tender spot over the region of the right kidney. Urine alkaline, contains some pus cells; sp. g. 1025.

Operation, 14th August 1898.—Kidney exposed by oblique incision and stone found with very little difficulty. The stone was composed of oxalate of lime and weighed 20 grains. The wound was drained and closed in the usual way, and she was discharged in a month.

CASE XIX.—Nephrolithotomy.—C. S., aged 17, Adamstown. Has suffered from pains in the back and loins for four or five years. Attacks of renal colic, followed by hæmaturia—pain referred to being both sides, but more particularly to right. Six months ago the right kidney was operated upon by one of our hospital surgeons, but nothing was found. As the symptoms did not abate, he was admitted to hospital under my care. He then complained of constant attacks of renal colic with hæmaturia, was very emaciated and weak. Pressure over the left kidney gave rise to severe pain. Urine alkaline, contained pus cells and blood cells; sp. g. 1030. The symptoms on this occasion pointed undoubtedly to the left kidney as the seat of the trouble.

On the 19th January 1899, I cut down by the oblique incision and brought the kidney well into the wound. Palpation revealed a well-defined hardness, but needling gave negative results. I then cut in through the cortex, and the knife impinged on the stone. Great difficulty was experienced in extracting it; in fact, one piece was broken off in the attempt. After the whole of the stone had been taken out, the kidney was a good deal lacerated and gave rise to a pretty smart hæmorrhage. Digital pressure did not altogether control it, so I put in four deep catgut sutures. The kidney was replaced, and the wound drained and closed in the usual manner. The stone was phosphatic in formation and weighed 260 grains. He complained of a good deal of pain for the first night, for which he had gr. $\frac{1}{2}$ of morphia. After this he recovered rapidly, and was up and about in three weeks.

CASE XX.—Nephrorrhaphy.—C. D., aged 26, unmarried, living at Waratah. Has complained of pain in the back and dragging in the loin for three or four years. Increased on exertion. When semi-prone, a tumour can be felt, in shape like the kidney, which falls back when she is in the recumbent posture. Urine normal.

20th March 1899.—Kidney cut down upon; capsule incised and separated; then each side stitched to the transversalis fascia and muscles. The wound was closed with silk-worm-gut.

Nothing further of importance occurred. She was discharged in three weeks. I have seen her once since; there has not been any return of the old symptoms.

CASE XXI.—Nephrolithotomy.—M. B., aged 45, nurse, Coonabarabran. This is a continuation of Case 5. After the last operation she remained in weak condition, unable

to do her work for about twelve months. Since then she has had the position of Hospital Matron, but has always had more or less pain in the left side, colicky in character and rendered worse on exertion. Always has a temperature of 100. Urine contains about a tenth of pus of low specific gravity; desire to micturate frequent.

There is a great deal of tenderness over left kidney, and particularly in one spot. The kidney appears enlarged.

On the 20th February 1900, I cut down upon and brought the kidney into the wound. It was enlarged, almost double the normal size, and sacculated. On incision, a quantity of most foul-smelling urine and pus escaped. The kidney was simply a cavity, at the bottom of which was a stone weighing 40 grains. The proper course would have been to have excised the kidney there and then; but being in doubt as to the condition of the organ on the right side, I lightly curetted the cavity of the kidney all over, and thoroughly irrigated it; then placed a drainage tube in the pelvis and closed the wound. For about ten days she had a good deal of pain, during which time she developed an attack of cystitis. After this subsided, she recovered sufficiently to leave the hospital in about five weeks.

CASE XXII.—Nephrolithotomy.—C. A., aged 32, polisher, Newcastle. Has suffered for years from severe pain in the right side, radiating towards the umbilicus and simulating hepatic colic, so much so that the operation of cholecystotomy was performed by one of the leading surgeons in a metropolitan hospital, but he says no stones were found. He was sent home after this, and remained in the same condition of pain.

He was admitted into Newcastle Hospital in February 1900. Condition very emaciated. Biliary fistula still open. Describes pain as colicky in character and descending into right testicle, which is retracted during paroxysms; has distinct pain on pressure over right kidney. Urine contains a few blood cells and lithic acid deposits.

February 22nd.—The kidney was explored, and a stone weighing 45 grains extracted, composed of lithic acid. His recovery was uninterrupted, and he was discharged in three weeks. I saw him a month since: he has gained flesh and has lost all his old symptoms.

From the foregoing cases I do not claim to have an extensive experience in renal surgery, but give them with the conclusions I have drawn from them.

Regarding the incision, I have always employed the ordinary oblique incision, excepting in the two cases of abdominal nephrectomy, and my reason for these was the very large size of the kidney. The oblique incision started from just below the last rib, close to the outer border of the erected spine, downwards and forwards towards the iliac crest. The costo-iliac space was increased as much as possible by a sandbag under the opposite loin.

Examination of the kidney can only be complete by bringing it well up into the wound and, if necessary, on to the loin. At first this may be a little difficult, but by

freely separating the peri-renal fat, it may be done in most cases with comparative ease. The most difficult cases naturally are those in which there is a large quantity of adipose tissue.

As to the value of needling the kidney in the search for the stone, I believe the use of the needle to be of the very negative value. Sometimes one will strike the stone at once, but in the largest stone I extracted I failed to find it with the needle. In nearly every case of stone, though, I have noticed a peculiar leathery sensation as if the needle were passing through chamois leather. I have noticed this even when I did not touch the stone with the needle.

Suturing the kidney.—In the later cases I have put two or three stitches of deep chromicised catgut if the hæmorrhage has been at all free and not easily controlled.

Length of incision in kidney does not appear to be of much consequence. In one case I almost bisected the organ in the search for the stone, and the man recovered just as well as those in which a small wound had been made.

Drainage.—In all cases the wound was drained by the ordinary rubber tube placed at the bottom of the wound, not in the kidney. The last case was drained with gauze placed in the same position, and removed the second or third day.

Suturing the wound.—The deeper layers of muscles were united with chromicised catgut, and the skin with silkworm gut. In no case has there been any trouble with hernia, or similar trouble.

Subsequent treatment of the cases consisted in a little morphia to relieve pain the first and perhaps second night. The majority of cases only required three or four dressings.

Urinary Fistula.—I have had none of these cases.

Regarding the *risks* of the operation, they appear to be very small. In Case No. 14, which terminated in such a disastrous manner, I believe this would have happened after any operation.

There was no cause apparent for such an unfortunate termination, and the circumstances were too distressing to press for a *post-mortem*.

In the other case which died, No. 16, the termination was almost a foregone conclusion, and I only operated at the urgent entreaty of the patient and her friends.

In none of the other cases was there any cause for anxiety after the operation, and the patient was put back to bed.

THE USE OF QUININE IN MALARIOUS FEVERS.

BY RAI KAILAS CHUNDER BOSE BAHADUR, L.M.S., C.I.E.

Fellow of the University of Calcutta.

THE subject has been almost exhausted, and any attempt to contribute further to its literature will, I fear, be simply an effort to bring into one place facts and arguments already urged by well-known members of our profession. It is therefore necessary that one should

be very brief and cautious in his remarks on the action of quinine in malarious fever. In ancient times, when the properties of cinchona and its alkaloids were unknown to the practitioners of our country, they trusted chiefly to vegetable bitters in treating their fever cases. We now find that most of these bitters were taken from plants belonging to the natural order of Rubiaceæ or Cinchonaceæ.

To Dr. TWining is due the credit of first experimenting on the action of quinine upon the fevers of India. Its use has now become universally known, and the kavirajes and hakeems who were at one time dead against it employ it freely in all cases of fever, though under a different name. The late Kaviraj ROMA NATH SEN used to say that the revival of the Hindu system of treatment and its progressive success in the cure of chronic malarious fevers dates from the introduction of quinine into the list of their febrifuges. The secret of success of the modern kavirajes and hakeems lies confined within the bottle of HOWARD & SON'S quinine. It is now admitted by people and practitioners alike that the timely exhibition of quinine in malarious fevers can save lives from almost inevitable death.

In my practice I absolutely rely upon quinine in the treatment of malarious fevers, and the results, I am glad to be able to say, have always been most satisfactory. It is simply waste of time to wait for a remission, or perfect intermission, for one cannot be too positive about the prognosis of a case of malarious fever however mild it may appear at its onset. Instances are not unknown where apparently uncomplicated cases of intermittent fever have assumed a pernicious form and killed the patient. The use of quinine during the hot stage of fever has often been followed by hopeful results. In remittent fever it should be given in small repeated doses, for big doses are apt to cause sickness, insomnia, and depression of spirits. Failure of the heart's action, which is a serious complication of remittent fever, may be prevented by the judicious administration of quinine from a very early stage of the disease. The action of quinine upon the cardiac centre is really not depressant, but at the same time one cannot too confidently recommend it in cases where symptoms of heart failure have already set in, for the sickness and vomiting which sometimes follow the use of quinine tell seriously upon the function of this organ. I have not seen a single case where the administration of quinine in remittent fever has been followed by disastrous results. Intermittent fevers yield rapidly to quinine. One big dose of 15 grains, shortly followed by another similar dose, rarely fails to cut short the fever and prevent its return. I am not prepared to say whether quinine totally annihilates the plasmodia or simply makes them inactive and less capable of multiplication. The temporary absence of the parasites from the blood after a big dose of quinine is no certain indication of their death. It is yet premature to say whether the plasmodia die out immediately on the exhibition of quinine, or simply remain dormant for a time, and then, under favourable circumstances, revive and multiply. I would here cite an instance where a gentleman was

subject to an annual return of intermittent fever (quotidian). The fever, as a rule, used to visit him during the month of June. It, however, yielded rapidly to quinine, and after a short confinement to bed for four or five days, he used to return to his duties. Under my advice he continued to take 8 grains of quinine daily for six consecutive months, and then went to Madhupur for a change. He returned to Calcutta in May, and got the fever in June. He took quinine and got himself cured. The next year the fever returned in June, and the patient obstinately refused to take quinine. The fever, which was intermittent before, soon assumed a remittent form of a severe type.

I have met with a few other instances of this nature. From such examples one can roughly conclude that the disposition of the malaria germs is very versatile, and that they can, under different circumstances, assume diverse forms. The same variety which in one case produces *tertian* will in another produce *quotidian*, and from *quotidian* the fever may become *remittent*. It is not absolutely true that the large varieties will produce intermittent and the small ones remittent.

We have, through the observations of LAVERAN, BIGNAMI, GOLGI, and others, been able to ascertain the cause of malarious fever and understand the character of its amoeba; but we do not know what is the actual fate of these germs when the system is saturated with quinine. The symptoms and complications of fever depend mainly on the amount of poison they generate, and not upon the special variety of the plasmodia. It is questionable whether one group of plasmodia produces one, and only one, special chain of symptoms.

There cannot be the slightest doubt that quinine is specific for malarious fevers, but at times its action upon an unmistakable case of intermittent fever is *nil*. I have very carefully observed that quinine in all its forms is inert in arresting, or altering, the character of double quotidian fever. Amongst numerous other cases, I give short notes of two where quinine failed.

Case 1.—HEMBALAL BATIA, aged 32, a Hindu Jain and dealer in Government opium, got fever with shivering at about 11 A. M., February 3rd. The fever subsided about midnight and the patient was absolutely free from it on the following morning. It returned again at noon and subsided during evening. The next day it came at 9 A. M. and left him at 3 P. M. It returned again during the night with shivering and left him with copious perspiration at 2 A. M. From February 6th to May 20th the fever followed one rule of coming twice within twenty-four hours, and then it altered its character and became very irregular in respect of the time of its coming and leaving. The temperature during the cold stage was 104°F, during the hot stage 104.5°F, and at times it went up to 105.8°F. The temperature of the night attacks was one degree less than of the day attacks. During the intermission it went down to 97°. Complications appeared in rapid succession, and eventually the patient succumbed. Quinine was exhibited in large, moderate and small repeated doses, but to no effect. It was injected hypodermically, but the result was equally futile.

Case 2.—A respectable Hindu lady, aged 16, married, living in a comfortable house, got fever, and placed herself under the treatment of an experienced officer of the Indian Medical Service and several other qualified practitioners. The fever was of double quotidian type; the diurnal paroxysms were preceded by distinct shiverings, accompanied by retching and vomiting, but the night ones were absolutely free from these unpleasant symptoms. Her temperature ranged between 105° and 106° during fever, and it went down to 97° during intermission. She was treated with quinine and arsenic, but the result was extremely unsatisfactory. The spleen became hypertrophied, and the patient soon became cachectic. She was sent up-country for change of air, but returned in a shattered state of health. Quinine was given hypodermically for seven consecutive days, and the result was disappointing. Cancrum oris and diarrhoea ultimately carried her off.

One special peculiarity observed in this case was that whenever quinine was given in fairly large doses the duration of the fever was prolonged and the period of intermission cut short. When given hypodermically, it had a marked effect upon the temperature of her body, but none whatsoever on the duration of the fever. The poor patient suffered continually for eighteen months, and for the first twelve months the character of the fever was uniform. Afterwards it changed its type and became persistent. Since this alteration in the character of the fever the temperature did not rise higher than 103°. Epistaxis and bleeding from the gums preceded cancrum oris.

I have seen wonderful effects of quinine in pernicious intermittent fever which, when neglected, killed its victims in two days. Fortunately this form of fever is not usually seen in Calcutta. I have within the last twenty years of my private practice seen only ten cases. It has, like all other intermission fevers, three distinct stages, but the intermitent, though complete, does not last longer than three hours. The second paroxysm is graver than the first, and the third is still more grave than the second, and the fourth brings on all the worst complications which, in the majority of cases, prove harbingers of dissolution. Quinine is the only thing to be relied upon in such cases. To discontinue quinine before the patient is rendered dumb, deaf and blind is not always a prudent course, for it is generally after the production of complete cinchonism that patients commence to manifest symptoms of recovery. The early exhibition of quinine is always advocated. Whenever we find that the prostration after the first paroxysm is very great, and when the period of intermission is only nominal, we should at once take the case as serious and try to bring the patient under the influence of quinine. It is wise to err on the right side. To give quinine in small doses in such cases is to court disappointment. I would here beg to give reports of two cases where the neglect of giving quinine in the early stage of the fever was followed by disastrous consequences:—

Case 1.—A respectable Hindu lady, aged 35, had fever with shivering. The cold stage lasted for an hour, and was then followed by the hot stage, which

was very prolonged; temperature 106.4° . No pneumonia, bronchitis or pleurisy; urine normal; intense headache and delirium. These symptoms lasted for twenty-four hours, and then the temperature commenced to fall until it gradually went down to 98° . The period of intermission was short and lasted only for a couple of hours. The fever returned during the afternoon with its usual severity, and lasted for thirty-six hours, followed by perfect, though short, intermission; 5 grs. of quinine were given at noon. At about 1 o'clock the patient complained of chill, soon followed by high fever. The temperature recorded at 10 P.M. was 107° . Along with the rise of temperature, head symptoms of a grave nature manifested themselves, and during morning, when a change for the better was expected, she had twitchings of the muscles of the face and rigidity of the forearms; her mind became confused, and she died before evening.

Case II.—BARY, a Hindu gentleman, aged 28, had intermittent fever with short intermission and general prostration. Grave symptoms manifested themselves during the second paroxysm. Temperature went up to 108° , and the patient became dull and apathetic; passed urine involuntarily; pulse 130—pretty good; respiration 26; no pneumonia. These alarming symptoms lasted for eighteen hours, and with the decline of temperature the patient gradually returned to consciousness. We commenced exhibiting quinine when the temperature was 102° , and in six hours the patient had 40 grains of muriate of quinine. We also injected 5 grains of the bisulphate hypodermically, and steadily pushed on the muriate until the patient became absolutely deaf. The result was excellent, and he recovered, though after a protracted convalescence.

Quinine lessens the activity of the white corpuscles and gives tone to the red, and reduces the size of the spleen. Its success in the treatment of chronic malarial fever is illustrated by the two following cases:—

Case III.—SHARBASIA, a bigoted Jain, aged 50, suffered from chronic fever and hypertrophied spleen. He was absolutely anæmic, with a hæmic murmur at the neck; gums spongy, susceptible to bleed on slight pressure; complete anorexia; vertigo and palpitation on slight exertion. Liver slightly enlarged; spleen painful on pressure, and extending down to the umbilicus. Refused to take medicines other than stalks and leaves of indigenous plants. After repeated requests of friends and relatives he made up his mind to take quinine pure and simple. He was advised to try 5 grains of the muriate of quinine three times a day. The improvement was very slow at the beginning, but was very rapid after the expiration of a month. His appetite returned, and within six months

from the commencement of the treatment he completely recovered his health. His spleen became normal; his anæmia and other unpleasant symptoms disappeared altogether.

Case IV.—BABANTIA, a respectable Hindu widow, aged 38, came under my treatment for enlarged spleen, fever and general weakness. She was anæmic; her menses scanty, but regular; heart, lungs, liver, and kidneys normal. There was considerable wasting of the muscles, total anorexia, sickness and vertigo. She would only take quinine in honey, and was accordingly permitted to take it in that fashion. Her improvement was most extraordinary, and when she returned to me after two months she was a new person altogether; her spleen nearly normal; no more fever; appetite fair; takes a lot of milk and digests it; can walk a mile without feeling fatigued or tired; sleeps well during the night, and is comfortable in every respect. She had not a grain of iron in any shape, and did not leave Calcutta for change of air.

To ensure the rapid and effective action of quinine, it is desirable that it should be given in the form of mixture; where 60 grains in pill form fail to cut short the fever, 20 grains in solution will succeed in producing the desired effect. The coated pills often take a long time to dissolve, and at times they are passed in their original form. As a rule, children and delicate women strongly object to take quinine in liquid form. To induce them to do so, it is necessary to cover its taste. I have seen powdered myrabolam when placed over the tongue and kept there for a minute entirely mask the bitterness of the alkaloid. Next to it comes pulv. glycyrrhizæ et zingiberis. When they are mixed up with quinine its taste is covered to a great extent. The former plan is good and harmless. In India myrabolam is readily procurable, and is often used as a mild laxative by all classes of people.

The addition of salicine increases the potency of quinine and gives satisfactory results; its combination becomes useful when the fever is chronic, and when quinine alone fails to shorten its duration. I do not remember to have ever seen an instance where quinine and salicine failed to alter the character of malarious fever and check it materially. There is, however, one fundamental rule which should be carefully observed in administering quinine to a patient suffering from malarial fever, and that is to see the liver unloaded.

Case V.—MONOHOR, a Hindu male, aged 32, resident of Rajpore, a village in the 24-Parganas, came under my treatment for intermittent fever of six

weeks' duration. The fever was of quotidian type ; used to come regularly at 2 P. M., and leave at 11 P. M., with copious perspiration. Hepatic dulness slightly increased ; spleen slightly enlarged ; lungs, heart, healthy ; no albumen in the urine. The patient stated that he gave a fair trial to quinine and got simply disgusted with it. He took it regularly for three weeks, but derived no benefit from it. I gave him 15 grains in one dose, and the fever returned as usual. The next day I combined salicine with it, 5 grains of each, and pushed this every three hours until he had taken 40 grains of quinine and 40 grains of salicine. The result was satisfactory. The patient had no unpleasant symptoms. The fever did not return. The following day he had no quinine, but 10 grains of salicine. The evening temperature recorded was 99°. Convalescence was rapid, and the patient soon recovered completely.

The presence of diarrhoea complicates matters, and quinine in any form simply aggravates the gastro-intestinal irritability and brings on complete anorexia. In such cases the exhibition of quinine should be withheld until the stools become normal.

Dosage of quinine.—The dose depends entirely on the character and duration of the fever. When the intermission is longer than twelve hours, small, repeated doses agree well with the patient. When the period of intermission is short, a full twenty-grain dose should be given at once, followed by another ten-grain dose after a couple of hours. When alarming symptoms manifest themselves from the very early stage of the fever, the patient should be cinchonised as quickly as possible. To wait for a perfect intermission is a mistake. Some complain of nausea or vomiting after a big dose, but there are so many things to check it that no special notice need be taken of it. To give quinine in big doses immediately before the paroxysm of fever is to court complications and troubles. The use of quinine through the rectum has not often been followed by satisfactory results. There is no doubt, however, that it is partially absorbed into the system.

Hypodermic injection instantly reduces temperature, but how this reduction takes place we cannot satisfactorily explain, for I have never seen perspiration follow this process ; on the contrary, it is checked or entirely arrested by it. Deafness and noises in the ear, which sometimes become sources of annoyance and discomfort to patients, can be easily removed by the addition of ergot to the mixture. It does not in any way impair its action.

Quinine, when given to patients who are subject to hysteria or insanity, is liable to upset them. I have seen a young man, who some years ago suffered from mental

aberration due to the excessive use of bhang, but who has since left off the habit, go mad after taking 40 grains of quinine in the course of twenty-four hours ; but such cases are indeed very rare.

Dyspepsia and diarrhoea, which sometimes, though very rarely, come on after a prolonged use of quinine, disappear altogether after its discontinuance.

I have observed that quinine sometimes, though very rarely, causes diffuse dermatitis, and the report of one or two cases will, I trust, be not out of place.

Case VI.—GONES DOSS, a Marwari, aged 55, came down from the Punjab to place himself under treatment for general dermatitis said to have been of three weeks' duration. He said he took quinine for the cure of fever to which he was subject. He always took medicines from hakeems, and never suffered from any unpleasant effects. This time, at the instance of a friend, he took quinine and got the disease. I never knew before that quinine could cause dermatitis. I prescribed for him an alterative mixture which he continued for ten days, but found no improvement. I consulted my friend, Dr. K. McLEOD, then Professor of Surgery in the Calcutta Medical College, and prescribed for the patient an ointment containing resorcine, ferri sulph. and lanoline. The relief was almost immediate, and he was all right very soon and returned to his own place. Three years ago he came down to Calcutta on business and got fever. I prescribed for him quinine in 5-grain doses. After taking four doses he complained of an itching sensation all over the body, and on the following day he had a return of dermatitis, which, however, yielded soon to resorcine and lanoline. On the appearance of the skin trouble quinine was discontinued, and the fever persisted for six weeks. During this time he took native medicines, but to no effect. His fever was quotidian. I gave him again one 15-grain dose in solution, followed by another 10 grains six hours after the administration of the first dose. The fever subsided, but the dermatitis returned and troubled him for weeks.

Case VII.—MAYIAPPA CHETTY, another Hindu Madrassé gentleman, of Canning Street, had fever, and was treated with quinine ; he took 40 grains in two days. He drew my attention to a sort of eruption, of the nature of urticaria, breaking out on his trunk and extremities. It had the same kind of itching as is commonly noticed in urticaria, but unlike it, the rash never faded, but persistently remained for four days, and was then followed by desquamation. He recovered ; no ointment was used. On a subsequent occasion this gentleman had hemiorania, and I gave him 20 grains of quinine. There was a return of the skin trouble, which continued for three days, and then faded after partial desquamation.

A MIRROR OF PRACTICE.

A CASE OF STERNAL DISLOCATION OF CLAVICLE.

BY Y. G. APTE, B.A., L.M.S.,

Assistant Surgeon, Memorial Hospital, Lushkar.

FRACTURES are commoner than dislocations in clavicle. The *f*-shape gives it an enormous elasticity, and when that is exceeded by violence from without it undergoes a fracture at the weakest spot. In fact, a dislocation of the clavicle would have been very much rarer than even now, if its ends had had better joints. As it is, the articulations at both ends are very shallow; the sternum, as well as the deromion, present very flat surfaces. It is true the ligaments are short and strong, yet the poor articulating arrangement allows a rupture of those ligaments when indirect violence is exerted upon them, especially when at some leverage, and thus a dislocation is produced.

The following case is an instance of such a rare dislocation, and as it has some points not usually mentioned in text-books, I have thought it worthy of record:—

A young man of 20 was admitted into the Memorial Hospital one morning, complaining of severe pain about the upper part of chest, difficulty in breathing and swallowing as from pressure on the trachea and œsophagus from front. This had come on all of a sudden while he was wrestling the previous evening. His opponent threw him over on to the floor by a smart trick (by his description it appears he reached the ground shoulder first, which thus received the brunt of the fall), and he felt the left collar-bone dislocating with a snap (presumably of the posterior ligament). He tried massage, but it was painful. The next morning the patient came to hospital in a particular attitude—left shoulder raised up higher than the right, and perhaps a little forward, the clavicle correspondingly distinctly seen more vertical than its fellow, the elbow supported by the right hand, the neck slightly inclined towards right. The position of the shoulder was thus exactly opposite to what it is in a fracture of the clavicle, in the classical description of which the patient leans on the fractured side, and the shoulder is lower than its fellow.

Apart from attitude, there was a noticeable physical sign in a depression at where should have been the inner end of the clavicle. The hollow was a fair size, almost that of the thumb, into which the bone, traced from without inwards, seemed to disappear.

Diagnosis was therefore dislocation backwards of the sternal end of the clavicle.

It may be interesting to inquire why the shoulder was raised up and supported at the elbow by the other hand. Pain and general discomfort was increased if this support was taken away. It would thus appear that raising the shoulder in some way tended to relief. In a case of fracture, also, the patient supports the elbow; but his object is to prevent the weight of the limb dragging down the outer fractured half of the bone. In a dis-

location the weight of the limb will act through a whole uninjured clavicle. The reason for raising the shoulder must, therefore, have reference to something outside the clavicle. In dislocation backwards (or, for the matter of that, forwards,) the weight of the limb will give it an upward character also. Now if we consider the anatomy of the part, we can see that an upward dislocation means greater pressure on the surrounding parts. The trachea and œsophagus are not placed vertically in the neck and thorax. There is a considerable deflection from the vertical in the antero-posterior plane, so that in projecting out of the thorax they come forwards. Hence any foreign body (like the displaced end of clavicle), press as it does already in being dislocated backwards, presses all the more if there is an upward tendency to it. I believe it is to relieve this extra avoidable pressure that the patient supports the elbow, and he raises it higher than the fellow, in order that the inner end of clavicle being thereby depressed, even the pressure due to the backward dislocation may be relieved to a certain extent, as the lower the sternal end descends, the more does it get away from the trachea.

Treatment.—I attempted to reduce the dislocation by standing behind the patient, placing the knee as a fulcrum on the spine and stretching the shoulders backwards, whereby I hoped the anterior end of clavicle would spring forwards into its place by the leverage exerted on the outer end. But it did not succeed immediately; and as discomfort to the patient, who was feeling pain and a choking sensation, was a consideration, he was laid flat on a fracture bed. That position, even with a narrow spinal pillow, was not sufficient to reduce the dislocation—as it usually is to reduce a fracture. The patient was therefore chloroformed, and reduction was attempted by manipulation—placing the tips of the fingers in the supraclavicular space, just outside the origin of the sternocleidomastoid muscle and lifting the bone forwards. This succeeded at once. The bone was in position: the question now was how to keep it so? Attempting to put on a figure of eight bandage, drawing both shoulders back, the bone displaced and was now as easily reduced by the pressure of fingers above and behind clavicle. No kind of bandaging was found to answer the indications. Simple rest on a flat bed was good enough, but it was not sufficient to prevent the bone from dislocating by even slight direct pressure. To go one better than simple rest, the following plan was thought out. The inner end of the clavicle gives attachment to some fibres of the pectoralis major. If that muscle were brought into action, the insertion being fixed, the muscular tension will pull upon the clavicle actively; and this was found to be the case. With the arm extended at right angles to trunk, and the hand grasping an iron bar at the side of the bed, the dislocation could not be reproduced by pressure. The patient was therefore asked to keep a gentle hold upon the bar as long as he conveniently could. Even passive position was found afterwards to be effective. It was inconvenient to lie for hours with an outstretched arm, which got cold and numb. Therefore the arm was next morning gently brought to the side and kept there without affecting the position of bone. Perfect rest for two more days,

and the patient could move about his shoulder without causing a dislocation—even gentle direct pressure did not produce it, and therefore he was allowed to go home, with an injunction not to exert the limb for a few days and not to wrestle for a long period. Having experienced what a distress the dislocation causes, the patient may safely be expected to take good care of the bone.

The noticeable points in the case, not brought out in the text-books, are : (1) the attitude of the patient as contrasted with that in a case of fracture of the bone ; (2) the help of muscular action, active and passive tension, in keeping up a reduction.

HYDROPHOBIA : TWENTY-FIVE DAYS' INCUBATION.

By T. M. SHAH, L.M.,

Chief Medical Officer, Junagadh State.

MASUMI DENSHER, male, aged 30 years, was early in the morning of 14th December last defecating in a sequestered portion of jungle outside the town, where he was attacked by a hyæna. The left hand was badly hurt, the terminal phalange of the middle finger was dis-jointed, besides the infliction of several small lacerations and indentations upon the same limb. The patient got up, caught hold of the animal by its neck, and threw it in an adjacent nullah. The patient immediately repaired to hospital, where his wounds were dressed ; the phalange, which was adherent by a tongue of skin on the dorsal aspect, was replaced and retained by a splint of pasteboard.

He had fever next day, temperature rising to 103° ; the limb was painful, the phalange died and separated in a few days, and the wound was nicely granulating and healing.

The patient was a healthy man. The immediate danger of tetanus passed away, and the patient was quite convalescent. There was no suspicion whatever about the animal being rabid.

In the evening of the 8th January, exactly the twenty-fifth day after the infliction of bite, the patient felt uneasy ; he had yawning and disinclination to take his supper. He did not sleep and was convulsed, and was shouting and howling all the night.

9th—Hydrophobia was unmistakable. He was furious, but quite rational. He solicited to be tied up to his bed, lest he might hurt any one. He could neither drink nor swallow. He hid his face, lay on his stomach, but his teeth had convulsive twitchings. He was restless, and was cursing several times. He tried to drink medicine, but could only half empty the cup with the utmost effort.

He was placed in BOUSSON bath. He perspired profusely. He had enema of milk 1 lb, with chloral hydrate 20 grains.

10th—He was given bath three times, and had enema of milk and chloral four times, but he had no sleep. He shouted violently all night. In the course of the day the patient became more quiet ; his speech became thick and slow ; convulsions lessened, and he lay in bed quiet and helpless. He could not get up without help. He began to drink and eat in small quantity, though with sobbing and difficulty. His pulse became weak and imperceptible, though patient was perfectly conscious.

11th—General paralytic symptoms were marked. He could not support his head. Vision and speech were lost. He could not swallow. Expired in the evening after three days' hydrophobic illness.

ASTHMA DUE TO GASTRIC DERANGEMENT : RECOVERY.

By M. H. GHULAM JILANI, C. M. S.,

British Agent at Birjand (Persia).

One night I was called to see a Persian lady who was suffering from a severe fit of asthma.

History.—Widow, 35 years, had suffered from indigestion and painful menstruation for 18 months, followed by similar asthmatic seizures. Premonitory symptoms to these attacks were itching and a tingling sensation on three right hand fingers, on which there were eczematous patches, and also severe headache. The patient was slightly anæmic, with a temperature of 98°, pulse slow and weak, and much restlessness from the wheezing and dyspnoea.

Treatment.—Forty minims of chloroform was given immediately for inhalation, and afforded prompt relief : this was soon followed by vomiting, which relieved the stomach. I then prescribed 15 grs. of chloral hydrate every three hours. After the second dose patient was much better and fell asleep, feeling practically well next morning. As she had apparently reached her climacteric period, although only 35, my treatment was next directed towards relieving her indigestion and painful menstruation. With this object I prescribed :—

Pot. bicarb.	10 grs.
Tinct. gentian co.	℥ 30.
Tinct. calumbæ	℥ 30.
Spt. chloroform	℥ 20.
Aque. anisi	℥ 3i.

three times a day : diet simple, and walking exercise. After a week the acidity of the stomach had subsided and appetite had been partly restored. The following was then given :—

Sodii hypophos.	10 grs.
Ferri et ammoniæ cit.	5 "
Spt. chloroform.	℥ 20.
Aque	...	ad	℥ 3i.

to be taken twice daily. This was continued a fortnight, and afforded the patient much relief. As the menstrual period had now approached, I prescribed the following :—

Pulv. myrrhæ	20 grs.
Pulv. rhei	6 "
Ferri carb.	30 "
Ext. Aloes	15 "
Syr. Zingib	q. s.

eighteen pills : 2 pills twice daily. There was very little pain with the menses on this occasion, but it was small in quantity. After an interval of fifty days the asthma returned. The same treatment was adopted with success, and after the fit had been combated, the following mixture given for a week :—

Liq. arsenicalis	℥ 5.
Syr. aurantii	℥ 3i.
Decoct. cinchon	℥ 3i.

twice daily after meals. After this the hypophosphite prescription was repeated, and myrrh pills also repeated about six days before the monthly course. The patient recovered fully. The menses became regular, the eczema disappeared, the appetite and digestion became normal, and there were no further asthmatic attacks for eight months later, when the patient left for Mecca.

Indian Medical Record.

13th March 1901.

TOTAL EXCISION OF THE SCAPULA ALONE AND WITH THE ARM, AND PARTIAL EXCISION OF THE SCAPULA FOR TUMOUR.

THE *Philadelphia Medical Journal* reprints from its columns recently an admirable monograph by Dr. J. J. BUCHANAN, M.D., of Pittsburg, Pa., Surgeon to Mercy Hospital, on Total Excision of the Scapula alone and with the Arm (interscapulo-thoracic amputation) and Partial Excision of the Scapula for Tumour. We essay a review. Patience and research are factors prominent in this production, containing not only the general history and literature of the operation, but also apparently complete tables of cases since the introduction of the operation. The history of the operation is practically cœval with the present century, in the first-half of which the principles and limitations of the operation were established, and in the second-half of which these principles were modified and the operation extensively practised. Dr. BUCHANAN classifies cases into the following groups:—

I. Total excision of the scapula with simultaneous removal of the arm (interscapulo-thoracic amputation).

II. Total excision of the scapula subsequent to disarticulation at the shoulder-joint.

III. Total excision of the scapula at one operation, with preservation of the arm.

IV. Total excision of the scapula at two or more operations, with preservation of the arm.

V. Partial excision of the scapula for tumour.

VI. Partial excision of the scapula with simultaneous removal of the arm.

Group I.—The first operation was generally attributed to RALPH CUMING (1808—recovery), the next to CROSBY (1836—recovery), and two years later TWITCHELL, of Keene, N. H., and McCLELLAN, of Philadelphia, successfully performed similar operations. In 1887 PAUL BERGER recorded the operation at some length, and since then it had very properly borne his name. Since that time 124 operations had been performed with but 13 deaths, or a mortality of 10.5 per cent., which was eminently satisfactory. This operation had been performed for a variety of indications: (1) *For injury*, by shot wounds, explosions, avulsion, crushing accidents, burns, and in one case by the bite of a wild beast. (2) *For neoplasm*—sarcoma, chondroma and carcinoma, but most frequently the first mentioned, from the upper end of the humerus. It was a matter for discussion whether in such cases disarticulation at the shoulder-joint should not be done, or even a resection of the upper part of the humerus. A comparison could not definitely be made until more satisfactory statistics were available; but in their absence it could be said, for the interscapulo-thoracic amputation, (a) that the lymphatic vessels and veins were removed at a higher level; (b) that the shoulder muscles, especially the deltoid and the scapulo-humeral muscles, are entirely removed, and that they are

frequent sites of secondary infection in growths originating in the humerus; (c) that the glands and fat in the axillary and subclavicular region are more accessible and more thoroughly cleared; (d) that the resulting wound is much more favourable for primary union than is the stump containing the overhanging acromion and the retreating glenoid fossa; (e) that it was extremely improbable that the statistics of shoulder-joint amputation would show a lower mortality than 10.5 per cent.; (f) that the difference in the resulting deformity was insignificant; and (g) that an examination of the table of cases under the second head showed that in a number of instances a disarticulation had been followed by recurrence in the scapula or its muscles, and that, in these cases at least, an interscapulo-thoracic amputation at first would have been preferable. These reasons appeared to the writer to be sufficient to justify the removal of the scapula and part of the clavicle in every case of malignant tumour requiring amputation at the shoulder. (3) *For necrosis following injury*. (4) *For tuberculosis*. (5) *For progressive phlegmon*. (6) *For painful cicatricial stump*. (7) *For gangrene of arm*.

In considering the treatment of malignant growth involving the bone or soft tissues below the level of the shoulder-joint, there must be borne in mind: (1) that the arm being such an important member, no amputation should be considered if there is a fair probability of completely extirpating all diseased tissue without destroying the usefulness of the forearm and hand; (2) that, therefore, early and complete excision is to be advised in every growth of the upper extremity; (3) that malignant growths of any part of the humerus (except possibly the less malignant giant cell sarcomas) require removal of the entire bone; and (4) that, therefore, in such cases an interscapulo-thoracic amputation should be performed; (5) that an arm amputated at or above the elbow is of but little service; and (6) that, therefore, in every case of malignant disease (except the giant cell sarcoma) requiring amputation at or above the elbow, an interscapulo-thoracic amputation should be made as a primary operation; (7) that considering the great usefulness of a forearm stump, and the probability of recurrence under any circumstances, no amputation should be made above the middle third of the forearm unless both bones are diseased or the soft parts infiltrated.

Method of operation (BERGER'S).—(1) Make an incision over the outer two-thirds of the clavicle through all structures, including the periosteum. (2) Separate the periosteum from the middle third of the clavicle. (3) Excise the middle third of the bone. (4) Isolate the subclavian artery as it passes under the bed of the clavicle, tie it at two points and divide. (5) Elevate the limb, and isolate, tie and cut the subclavian vein in the same manner. (6) Start an anterior incision at the middle of the one already made, and extend it downward and outward to the anterior fold of the axilla; continue it backward across the inner surface of the arm at the level of the axilla, and extend it downward to the lower angle of the scapula. During this portion of the operation the arm should be kept at a right angle to the body. (7)

Deepen this incision in front, severing both pectoral muscles and exposing the contents of the axilla. (8) Sever the cords of the brachial plexus at the level of the upper stumps of the vessels. (9) Start a posterior incision at the outer end of the clavicular incision, and extend it directly downward over the spine of the scapula and prolong it till it meets the anterior incision at the lower angle of the scapula. (10) Dissect the skin and subcutaneous tissue backward to expose the muscles at the upper and inner borders of the scapula. (11) Cut the attachments of the trapezius muscle, the omohyoid, the levator anguli scapulae, the rhomboidei and serratus magnus, drawing the scapula out from the chest and passing the fingers under the muscles, wherever possible, as they are cut, controlling with forceps the vessels as they appear, the most important of which is the transversalis coli. (12) The bone can now be drawn away from the chest, and the entire limb removed by severing such attachments as remain. (13) Tie or twist all vessels. (14) Make one or more counter-openings for drainage tubes. (15) Suture accurately. In Dr. BUCHANAN'S own two cases, both of which were successful, the anterior incision was made before the ligation of the subclavian vessels, and the vessels were exposed under the severed pectoral muscles and followed up from below to the point of subsequent ligature. The advantage of this was that there was no difficulty whatever in isolating the vessels, and any embarrassment from hæmorrhage is avoided.

The writer then gives in tabular form a succinct account of the known cases since 1808 to 1900, embracing in all 181 cases. In these we are pleased to see noted four Indian cases—three the work of Dr. McLEOD, late of Calcutta, one of which resulted in complete recovery, and one the work of Dr. G. C. HALL, of Allahabad, a complete success, details of which are taken from our own journal, the *Indian Medical Record*. The operative mortality for all these cases was 29 in 181, or 16 per cent. Of 70 cases in which the remote result was known, 13 remained free from recurrence for three years or more, i.e., 18.6 per cent. cured beyond the 3-year limit. Of 15 cases of sarcoma in which the remote result was known, three remained free from recurrence for three years or more, i.e., 20 per cent. cured beyond the 3-year limit.

Group II.—In a table giving 31 cases in which total excision of the scapula was undergone subsequent to disarticulation at the shoulder-joint, the writer shows that 23 were due to malignant growths. Of these, 16 cases recovered from operation and with known history, one only remained free from recurrence beyond three years, i.e., 6.25 per cent. of ultimate cures.

Group III.—The operation of total excision of the scapula, with preservation of the arm, had been aptly termed by Sir WILLIAM FERGUSON the “*ne plus ultra* of conservative surgery.” It was certainly an operation most gratifying in its temporary results in malignant disease and in its permanent outcome in other conditions. Nearly all writers considered those operations total in which but a small part of the bone was left; but the gradations in the amount excised were so imperceptible that no satisfactory line could be drawn. The writer drew the line absolutely

between total and partial excisions, but appended a “combination statistic” to include “total and nearly total excisions.”

To **Group IV** a table was annexed showing a small number of cases in which the entire scapula had been removed at two or more operations. These, from an operative point of view, had at no period been more than partial excisions. The indications for entire removal of the scapula were morbid growths, necrosis, osteomyelitis, tuberculosis and injury. As to the question whether the entire scapula should be removed in all cases of malignant disease, the number of cases on which the opinion favouring partial excision in small growths was based was too small to reverse the principles which governed the treatment of malignant disease in other bones; but there was sufficient basis for following a conservative course in small growths till further statistics were available.

Method of operation.—The incision most generally adopted was the T-shaped, practised by SYME. The U incision had been recommended by others on account of sloughing. The flaps, having been shaped, are dissected from the underlying bone. The trapezius and deltoid are separated from their attachment to the acromion and spine of the scapula, and the supraspinatus separated near its insertion. The inner border is freed by dividing the levator anguli scapulae and the rhomboidei close to their insertions. The posterior scapular artery is now ligatured. The inner border of the bone is lifted from the chest, and the serratus magnus cut through close to its attachment. The upper border is then cleared and the omohyoid divided and the suprascapular artery tied: the arm is drawn downward and the acromioclavicular attachments separated and the coraco-clavicular ligament divided: the inner border tilted forward and the teres muscle and infraspinatus divided, the subscapular artery being secured: the biceps, coraco-brachialis and pectoralis minor are divided: then the capsular ligament of the shoulder-joint is severed with the long heads of the biceps and triceps and the scapula removed completely.

With reference to the remainder of this excellent monograph, we can afford but a brief summary. It is undoubted that interscapulo-thoracic amputation is primarily a very successful operation, especially when performed for neoplasm, the mortality in such cases, since the general practice of antiseptics, being only 8 per cent. Of the cases amputated for sarcoma and other malignant growths, whose subsequent history was definitely known, 18.6 per cent. were cured beyond the 3-year limit as indicated above. It was evident from the tables that, compared with other operations, excision of the scapula subsequent to disarticulation at the shoulder is less practised now than formerly, probably owing to the increasing popularity of the interscapulo-thoracic amputation. The immediate mortality of the consecutive operation for neoplasm since antiseptics had been 6.6 per cent., but the fact that the mortality of interscapulo-thoracic amputation during the same period was only 8 per cent., while the percentage of ultimate cures of malignant cases by the interscapulo-thoracic was 18.6 per cent., as against 6.26 per cent. after the consecutive excision, confirmed the wisdom of the general preference now displayed for the primary major operation. Notwithstanding the excellent functional result of total excision of the scapula, the tables indicate that it is not advisable to remove the entire bone if a satisfactory excision of less can be made. If, however, the entire body or more be implicated, then both the immediate and remote prognosis were improved by a total removal of the bone. Dr. BUCHANAN, in considering the question when a case of malignant growth may be taken as cured, points out that 93 per cent. of the known recurrences, or deaths from recurrence, took place during the first three years after operation, and that, therefore, it was safe to adopt the classical rule of considering as cured those patients who had passed three years without recurrence.

ANNUAL REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR THE YEAR 1899.

IV.

VITAL STATISTICS OF THE GENERAL POPULATION.

In this portion of his Report the Sanitary Commissioner gives us an insight into some of the conditions that influence the well-being of the native population of India.

The subject is a large and complicated one, with which the present machinery is quite incapable of dealing. Only the most salient features are dealt with, and with regard to these, the impossibility of obtaining reliable figures is freely admitted, and the many difficulties that beset the path of the vital statistician pointed out.

"In the following pages," to quote from the Report, "little more is attempted than a broad survey of the outstanding features of the figures relating to births and deaths in the different provinces. These prefatory remarks will prepare the reader for general indications only of the ebb and flow of the chief vital phenomena, the resultant of many factors which are lost or obscured in the general movement; the material for refined speculation on some most interesting problems is wanting."

BIRTH STATISTICS.

The number of births registered in 1899 was not only higher than the average for the previous five years, but also higher than in 1898. This increase occurred in every one of the ten provinces into which the empire is divided.

There were altogether 1,670,491 more births registered in 1899 than in 1898. This is an enormous increase, and is attributed to the increased prosperity of the people, and as an indication of the generally higher standard of health which marked the previous year. The Sanitary Commissioner is at some pains to trace the influence of famine, religion, habits, etc., upon the birth-rate.

The infantile mortality statistics are evidently very imperfect, and the report mentions the extraordinary contrasts exhibited by them. Of course they are higher in cities than in rural districts; the mean figure for Bengal is 184.8; that for Calcutta 366.8. In the Bombay Presidency the mean figure is 192.7; in the city itself we have the enormous figure of 798.6.

DEATH STATISTICS.

In six of the ten provinces the death-rates were higher than in 1898; but then 1898 was an exceptionally healthy year. In the Punjab, Madras, Assam, and Coorg the rates were even lower than in 1898.

The death-rate varied from 20.1 per 1000 in Madras to 39.9 per 1000 in Berar. The figure for Bengal was 31.2.

GENERAL DISEASES.

Cholera.

Cholera was far less prevalent than usual: the death-rate was only 0.78; against a five-year average of 1.64.

Anti-cholera inoculations were continued at the Puralia and Balkeo ooclie depôts in Bengal, but the

number of cases fell off owing to the absence of the disease in an epidemic form.

Dr. POWELL, who is well known as a careful observer, is quoted as giving the following testimony in favour of HAFKIN'S cholera prophylactic method:—

"There have been 198 cases with 124 deaths among 6,549 persons not inoculated, compared with 27 cases and 14 deaths among 5,778 inoculated individuals. Had the incidence been the same in both classes, the inoculated would have had 174 instead of 27 cases, and 109 deaths instead of 14; the mortality, therefore, among the non-inoculated was nearly eight times greater than among those inoculated."

As we have remarked on a previous occasion, the seasonal incidence of cholera in Madras is usually very well marked, and on this subject the Report comments as follows:—

"The Sanitary Commissioner of Madras gives interesting tables showing the seasonal incidence of the disease in the different areas, which are divided into two groups in accordance with their geographical positions, and the consequent climatological conditions, as mainly influenced by the two annual monsoons. As he has been able to show in previous reports, the incidence of mortality is greatest in the south-west monsoon districts during the progress of the south-west monsoon, that is to say, during the June to September period; whereas in the north-east monsoon group the mortality is greatest during the prevalence of the rain current, which specially affects these particular areas, that is to say, during the last quarter of the year. Whatever view be held as to the effective relation between rainfall and cholera, there can be little doubt that, year after year, a definite relation in time is established in the two contrasted areas in the Madras Presidency—a relation, moreover, which finds supporting evidence in the seasonal prevalence of the disease in other provinces, and which is opposed to the usual sequence of events in Lower Bengal."

In the province of Coorg there was not a single death from cholera during the year; this, however, is nothing unusual in this favoured province, for the same thing has been recorded in 17 out of the last 21 years.

In Bombay cholera caused 8,579 deaths throughout the presidency. In Lower Burma there were 4,492 deaths; in Upper Burma the deaths in twelve selected districts numbered 2,050.

Interesting details are given of the more important cholera outbreaks in jails and amongst troops, which considerations of space prevent us reproducing.

Further evidence was afforded of the value of judicious movement of bodies of men among whom the disease had broken out, though it is recognised as only one of a series of precautions that have to be taken.

Small-pox.

The mortality ratio was reduced by 17 per cent. from the previous year, and by 43 per cent. from the quinquennium—1894-98—which shows satisfactory progress.

Ignorance, prejudice and the occasional prevalence of the old custom of inoculation help to keep the figures up in many places.

Cuttack was severely affected, and the Civil Surgeon reports that the people resort to inoculation in Salepur, Jagatsingpur and Jaipur: cases were sent for trial, and heavy fines inflicted on conviction.

In the Brahmaputra Valley many large sections of the people entirely refuse vaccination, and it cannot legally be forced upon them.

In Madras the old scare about plague inoculation had its effect, the people hopelessly mixed the two operations, and the opinion existed that plague was being spread amongst the people under the guise of vaccination.

In Coorg the same fear existed, but the people are reported to have recovered their confidence in vaccination.

In Bombay attention is directed to the good vaccination work done throughout the presidency. In Burma the importation of small-pox and its dissemination throughout the province are attributed to the unprotected coolie immigrants from India, large numbers of whom come to the country during the harvest season to reap the rice crop; its further spread is assisted by the practice of inoculation, which is said to be general throughout the province.

Plague.

There was a great increase of plague mortality in Bengal, the Central Provinces, Bombay, Madras, Mysore, and Hyderabad.

The number of reported deaths during the year was 139,009, against 116,285 in 1898.

A considerable space is allotted to a discussion of the part played by animals and insects in the spread of the disease. Particular attention is now paid to the flea. We learn that there are from 60 to 80 different kinds of fleas, and that nearly every animal rejoices in its own particular flea. It is an interesting subject for future investigation to what extent, if at all, fleas peculiar to one animal will prey upon another.

The general opinion appears to be that the possibility of the agency of insects could not be disregarded, yet that it was not distinctly proved.

The following, said to have been written by a member of the German Plague Commission, sums up very well our present knowledge on the subject of the transmission of plague:—

"The plague is spread in two ways—first, from man to man: (a) by contact, and (b) by inhalation; secondly, from the surroundings of man to man; (c) by contact with infected inanimate objects; and (d) by the transfer of the contagion from rats to man. We have no difficulty in explaining (a) as the penetration of plague germs through wounds or scratches, and (b) as the inhalation of minute germ-laden drops of moisture from the lungs of a plague patient. But the second method is less simple. No doubt contact with infected clothes is to be explained as in (a). But it is more difficult to understand why living among infected surroundings, i.e., in an infected house, should cause infection without there having been any proved "contact." In this connexion we have the disease of rats as an important factor—a factor not similarly observed in the case of any other infectious disease.

Rats generally suffer from a form of plague which occurs in man very rarely, if at all, namely, plague of the intestines. When thus diseased, they evacuate great quantities of plague germs. It is probable that numbers of plague cases among human beings are due to contact with evacuations of diseased rats, e.g., in the case of the flooring thus contaminated being trodden on by the naked foot. Less probable is the inhalation of such germs in the floor dust, because plague germs are easily destroyed by desiccation. Children often infect themselves by crawling on the floor, and then putting their fingers in the mouth, thus getting plague with neck buboes. A second possible method in which rats might convey the plague to human beings is by fleas. It is scarcely to be doubted that a flea which has bitten a sick man, and then bites a healthy man, can thus inoculate with the plague, though it is not clear that this method is as frequent as many investigators—e.g., the French school—are inclined to think. This much is certain, namely, that there are from 60 to 80 different kinds of fleas, and nearly every animal rejoices in his own particular kind of flea; so also rats. Now it is understood that fleas go from beasts to man; but it is not so certain that they will all bite man. No doubt a flea need not actually bite in order to infect. If it causes itching by crawling on the skin, and the person concerned rubs at himself to allay the itching, he may conceivably rub the infected blood from the flea into his own system. It is also asserted that the fleas infesting man are of catholic tastes, i.e., go over to beasts, e.g., rats, and then return, infected, to human beings. Infection by fleas becomes rather doubtful through the fact that in India the relatives of the sick have often, though not sick themselves, been taken to the hospital and have rarely fallen ill, though they most probably have brought fleas in their clothes which might have conveyed the disease from the patients to themselves. It is also on the flea theory of infection, not easily intelligible, why doctors and nurses are so rarely attacked. The question of infection of plague by fleas cannot, therefore, be readily answered at present. The fact that when infected houses are once well cleaned and aired, they do not give rise to further attacks, also speaks against the flea and bug theory, for these are not so readily driven out from houses."

Fevers.

But a short space is allotted to fevers. The number of deaths rose from 3,868,781 in 1898 to 4,126,384 in 1899, and this latter figure is below the five-year average.

Regarding fevers in Madras town, a subject to which we called attention some time ago, we read: "It must not, however, be considered that malaria is the sole cause of fever in Madras town. Typhoid fever is by no means uncommon." This was exactly our contention.

A special portion of the Sanitary Commissioner's Report is devoted to a history of vaccination and another to military and civil sanitary works: they do not, however, call for any special notice.

COMMENTS AND NEWS.

DEATH OF DR. DONALD MORISON OF BENGAL.

By the death of Donald Morison, M.D., late of Rampur Boalia, Bengal, our Society loses one of its corresponding members, the English Presbyterian Church a valued missionary, and India a true friend. Dr. Morison returned last June from India in a very poor state of health, and settled with his wife and nine children in Scotland. He made apparently good progress towards recovery, and was looking forward with much pleasure to a return to his beloved field of labour, when, on the 12th December, he had a serious relapse. He at once felt that his time was come, and gave parting messages to all his children. He was taken to the Glasgow Hospital for an operation, but died there on the 14th, making a triumphantly happy end.

Of Dr. Morison's devoted labours as a medical missionary, it will be for others to speak with a competence that we cannot claim. But for the anti-opium cause we can say that it has lost in him one of its most ardent, most enlightened, and most useful advocates. His interest in this question was the result of a decision of our Committee. Until 1889 it had been generally supposed that the opium curse was practically confined to China, except that the ravages caused by it in Burma had become known through the publication of Sir Charles Aitchison's report. Notwithstanding reports that had from time to time appeared as to opium-eating in Assam and Orissa, and smoking in the opium-dens in Calcutta (described by Mr., now Bishop, Thoburn in the *Indian Witness*), it was generally understood that the Indian Government had acted upon the policy laid down by the Directors of the East India Company in 1817, when, in sanctioning measures adopted by the Bengal Government for the supply of opium "for internal consumption," they explained that this sanction was given, "not with a view to the revenue which they may yield, but in the hope that they will tend to restrain the use of this pernicious drug . . . to prevent its introduction into districts where it is not used, and to limit its consumption in other places as nearly as possible to what may be absolutely necessary." But in the year 1889 Mr. W. S. Caine called attention to the scandal of the opium-dens at Lucknow in a striking article; about the same time the *Bombay Guardian* called attention to similar evils in Bombay. The Committee felt it desirable to obtain further information on the subject, and accordingly decided to issue, through the various Missionary Societies at work in India, a circular of enquiry. Mr. Donald Matheson, then Chairman of our Committee, was the regular correspondent, on behalf of the English Presbyterian Church, of Dr. Morison, its missionary in Bengal, and wrote to him on the subject. Dr. Morison's first reply was to the effect that "he knew very little about it, but he would make enquiry," although he had for 12 years been labouring as a medical missionary in the district of Rajshahi. But when he came to make these enquiries, and visited for the first time the licensed opium-dens, he found that the terrible habit of taking opium had, to use his own words, "been growing up around me all unnoticed and unknown," that it explained various facts which he had observed without understanding their bearing, that the number of opium-smokers was "far greater" than he had suspected, and that the habit was "spreading at an alarming rate."

The striking letter in which Dr. Morison recorded his visits to the opium-dens was forwarded by Mr. Matheson to the *Times*, and published by it. Reproduced by our Society,

and followed up by other similar testimony from various parts of India, it undoubtedly contributed to the Parliamentary victory gained by Sir Joseph Pease in 1891, and to the decision of the Indian Government, first, to withdraw licenses from opium-dens (*i.e.*, places where opium was allowed to be smoked on the premises), and, subsequently, to cease the issue of licenses for the sale of opium-smoking compounds. For these valuable reforms the people of British India owe a lasting debt of gratitude to our departed friend.

When the Royal Commission on Opium—cleverly designed and used by the Indian Government as a means of defending its opium revenue—visited Calcutta in the autumn of 1893, Dr. Morison came down thither to give his valued services, both as a witness and as an adviser. His long medical experience in one of the most malarious districts of India enabled him to expose the fallacy put forward by the official medical witnesses, and eagerly embraced by Sir William Roberts, as to the use of opium as a prophylactic against fever. He also paid a visit to Orissa, one of the chief opium-consuming districts in India, and brought back from it valuable evidence, which he laid before the Commission, disproving the theory that there it was used on account of any such protective utility. The evidence was rejected by a prejudiced Commission, which (with the exception of Mr. H. J. Wilson, M.P.) was influenced by the Marquis of Lansdowne's unconstitutional warning against interference with the Indian revenue and by the strong pressure of Indian official opinion, and closed its ears to the strong evidence of independent witnesses, native and missionary, as to the evils caused by the indiscriminate sale of opium in India. But the day will come—for truth is stronger than error in the long run—when Dr. Morison's calm, scientific evidence will be justified by the verdict of posterity. In that day India will doubtless honour the memory of one who loved her enough to boldly urge her protection from the insidious curse of opium, at the cost of no little social contumely, before which even missionaries too often shrank back.

Dr. Morison was a frequent and most valued contributor to the columns of the *Indian Medical Record*. We mourn his loss and offer our respectful sympathy to his bereaved family.

BEWARE OF THE MOSQUITO.

THE Liverpool School of Tropical Diseases has issued a "memoir" which is full of interest, as it relates the story of the practical attempt of a body of experts to solve the mystery of malaria. The following are the rules given as the result of the observations which have been made:—

- (1) Avoid being bitten by mosquitoes.
- (2) Kill mosquitoes and their larvae, especially *anopheles*.
- (3) Invariably use mosquito nets.
- (4) Empty all pots and vessels containing stagnant water at least once a week.
- (5) Brush out with a broom all puddles containing larvae.
- (6) Use punkahs.
- (7) Keep cisterns and wells covered.
- (8) If useless collections of water in which mosquitoes breed cannot be filled up or drained, recourse must be had to methods of killing the larvae chemically, or, as the writers state, use *culicicides*.

The simplest *culicicide* is kerosine oil, applied by painting the pool with a rag fixed on a stick and first dipped in a pot of oil. Quicklime and fresh tar are also effective, but all these either involve too lengthy a process, or would harm other life besides that of the mosquito larvae. The inventive genius of the chemist still has to discover the ideal *culicicide*.

It should be some cheap solid or powder which kills larvae but not higher animals, and dissolves so slowly as to render a pool uninhabitable by larvae for a long time.

The mosquito net recommended is one which has the roof as well as the sides made of netting, not of long cloth, which often is used. A loose frill or valance sewn on the net a foot above the mattress, and also tucked under it, is suggested as an additional precaution. It is becoming increasingly known that mosquitoes, although not the cause of malaria, are the means of introducing it into a healthy subject. Of all the species of mosquito it is the female of the *anopheles* which causes the trouble. In these the proboscis is long and thick, the wings are generally spotted, and when at rest on a wall the body is held almost horizontal. The larvae are generally formed in natural collections of water where they float flat on the surface. If these are destroyed, therefore, the nurseries of the young *anopheles* are destroyed also; hence the necessity for draining swamps is at once apparent on scientific grounds. The good resulting from such a procedure has long been endorsed by practical experience.

The journal of The Sanitary Institute, which has just been issued, contains a long article by Prof. A. CELLI, of Rome, on researches on the propagation of malaria and the precautions to be adopted in unhealthy districts. After describing some of the opinions of other investigators, he gives reasons for deciding that the dappled-winged gnat known as *anopheles* is the propagating agent. He then describes the life-history of the insect, and sets out a series of corollaries for the Hydraulic Engineer, for the Sanitary Engineer, and for the agriculturist, in which are detailed the steps that can be taken to prevent the multiplication of the *anopheles*, and other measures against the spread of the disease. The concluding portion of the paper gives instructions for the self-protection of labourers in malarious places. The paper is illustrated from some of Prof. CELLI's photographs showing methods protecting houses and shelters.

APPEAL FOR FUNDS FOR THE ENDOWMENT OF QUEEN-EMPRESS OR VICTORIA SCHOLARSHIPS.

THE late Queen-Empress was Patron of the National Association for Providing Female Medical Aid to the Women of India, otherwise known as the Dufferin Fund; and Lady CURZON, the President of the Fund, has issued the following appeal for funds for the endowment of Queen-Empress or Victoria scholarships by which to commemorate the late Patron of the Association. The terms of the appeal are given as follows in the daily papers:—

The Central Committee have already placed on record their deep sorrow at the death of the Patron of the Association. As a mark of respect to Her Majesty's memory, the general annual meeting, usually held in Calcutta, has been cancelled. Being, therefore, deprived of the chief opportunity afforded me of publicly appealing for assistance, I now do so through the Press. Few people, I think, are aware how keen a personal interest the Queen-Empress has always taken in the affairs relating to this movement. Its existence was due to Her Majesty's initiative. She has annually presented gold and silver medals to students at the chief Universities in India, and has on several occasions been personally addressed on questions connected with the policy of the Association. A matter in which the Queen-Empress took special interest, which the Dufferin Fund has up to the present been unable to sufficiently encourage, owing to lack of funds, regarding which about eighteen months ago she

telegraphed to me her hope that we should be able to promote its success, was the training of a greater number of native midwives to work in *zananas*. Her Majesty fully realised the difficulty of persuading the women of this country to leave their homes, and was always anxious that we should encourage trained midwives to practise in outlying districts. I now hope, if it is possible, to establish an Endowment Fund, the interest accruing from which shall be solely used in forming Queen-Empress or Victoria scholarships for training native midwives of suitable caste in hospitals or schools which lie nearest to the localities in which they would be ultimately engaged. I feel sure that there will be many persons who would like to help, in founding these scholarships, to contribute to the object which Her Majesty was known to have very much at heart, and which will do much to relieve the suffering women in India. The fact that I have received numerous testimonies of grief felt by the women of this country at the death of their beloved Sovereign leads me to issue this special appeal, in the hope that it will meet with their sympathy. It may be in the power of some native ladies of position and influence to give me their assistance by organising the collection of subscriptions for the above-named object. All contributions may be forwarded to me personally, and will be duly acknowledged. I shall be grateful to any persons, European or Indian, who will lend their help in the various provinces and cities.—
MARY CURZON.

AMERICAN TRIBUTE TO THE PASSING OF A GRACIOUS SOVEREIGN.

THE *New York Medical Journal* says:—There is probably no person in the world whose fatal illness could have caused the widespread sorrow and sympathetic reverence and respect occasioned by that of Queen VICTORIA. The termination of her long and arduous life, which, in the ordinary course of events, could not have been long delayed, forbade us to expect much from the greatest resources of medical aid and skill at her disposal; but the efforts of those who were privileged to minister to her—privileged, not because she was a queen, but because, being a queen, she had been all that she was in every capacity of life—have been followed closely with the warmest prayers of the world at large in their support, and with its tenderest sympathies. For this reason the names of Sir THOMAS BARLOW, Sir DOUGLAS POWELL and Sir JAMES REID will be preserved in history, irrespective of their services to medical science in general, as those who bared in her last moments for the most universally beloved monarch that ever sat upon a throne. The medical profession in all countries will ever cherish the memory of a sovereign who constantly interested herself in the relief of suffering, who held medicine in high esteem, and who was the first British monarch to publicly recognize the importance of medical sciences by conferring a patent of nobility on a medical man.

DR. DEWAN GANPAT RAI.

It will be of interest to many of your readers to learn that Dr. DEWAN GANPAT RAI, late of Lahore Medical College, who on return to England from the Thirteenth International Medical Congress, held in Paris in August 1900, took charge of an old-established practice of a well-known surgeon in the north of England, was on the 18th January last appointed to the office of Deputy Medical Officer of the Bishop Auckland District and Workhouse of the county of Durham in England. The Workhouse, or the Union Infirmary, contains 250 beds. Dr. GANPAT RAI has also been appointed Deputy Public Vaccinator of the District, for which he had to show proof of high proficiency in the practice of vaccination. In addition to these duties Dr. GANPAT RAI is Surgeon in charge of three collieries, employing over two thousand men. Within six months

of his arrival in England Dewar GANPAT has obtained the Tripple qualification of the University of Edinburgh, with honors, and headed the list of successful candidates, and ever since he has been engaged in a special study of surgery. He is now intending to go up for the next I. M. S. Competitive Examination.

TRAINING OF MALE AND FEMALE NURSES IN MADRAS.

THE following notice appears in the Fort St. George Gazette of Madras :—

In view to the efficient training of women as nurses and ward attendants and of men as ward attendants for employment in private and up-country hospitals, the Government is prepared to admit probationers of these classes recommended by local or private bodies, such as the Lady Dufferin's Fund Committee, into the General Hospital Training School for Nurses, on the understanding that such bodies shall arrange to defray the (i) pay, (ii) ration money, (iii) clothing, travelling expenses, &c., of such probationers. Volunteers who are willing to pay all necessary expenses, and who are approved by the Matron Superintendent, will also be admitted.

2. Quarters (for nurse probationers only) will, as far as possible, be provided by Government at the General Hospital, but there is no objection to other arrangements being made by pupils subject to the approval of the Matron Superintendent.

3. All applications should be made to the Matron Superintendent, General Hospital, Madras.

I. M. S. COMPETITIVE EXAMINATION.

THE following is a list of the successful candidates at the I. M. S. Competitive Examination held in London on February 8th :—

	Marks.		Marks.
A. G. McKendrick ...	3,449	C. B. McConaghey ...	2,611
G. E. Charles ...	3,392	W. D. Bitchie ...	2,591
J. W. Little ...	3,090	G. O. L. Keraus ...	2,590
St. J. Moses ...	3,003	E. W. Browne ...	2,575
N. E. H. Scott ...	2,911	E. C. Hepper ...	2,567
H. B. Foster ...	2,862	F. T. Thompson ...	2,486
G. B. Butt ...	2,842	J. W. Illius ...	2,478
C. E. Southon ...	2,788	J. B. Christian ...	2,417
H. R. Nutt ...	2,780	L. P. Brassey ...	2,391
J. K. S. Fleming ...	2,740	G. Fowler ...	2,357
H. W. Illius ...	2,704	A. Murphy ...	2,219
F. W. Sumner ...	2,703	S. Bose ...	2,212
J. A. Barnes ...	2,700	P. L. O'Neill ...	2,188
J. Husband ...	2,627	C. F. Marr ...	1,896

In the advertisement announcing the examinations, it was stated that twenty-nine appointments would be offered, and it will be observed that twenty-eight have been given.

Among the successful candidates are five Anglo-Indians, one Armenian and one Bengalee.

OPOTHEAPY IN CHINA AND INDO-CHINA.

JULES REGNAULT (*Revue de Medecine*) says that in these countries the testicular juice of the tiger is used for impotence. Under the supposition that the eyes and the liver are closely connected functionally, mosquito eyes mixed with pig's liver is given for conjunctivitis. Pig's liver is also given for icterus, congestion of the liver, and hepatitis. Goat's liver mixed with various plants is administered for diseases of the eyes or of the liver. Bear's gall is highly esteemed for the same purposes, but is very expensive. Pig's lungs are used for cough, especially in chronic bronchitis. Pig's kidneys are prescribed for renal affections. For gastritis the coats of a young chicken's gizzard are supposed to be curative. Women take pieces of dried placenta to facilitate labor. Human blood is supposed to be strengthening, and at executions the executioner, and even the spectators, eat the blood, the liver, and the bile of the victim to increase their courage.

EXECUTION BY POISON.

ACCORDING to the *New York Medical Journal*, Mr. H. B. Passager moved in the Indiana House of Representatives on January 21st that the method of executing criminals be changed from hanging to the administration of morphine. The motion was tabled. The idea of execution by poison is not of course a novel one. The method was in common use in antiquity, and various agents were used. The most

famous instance was the death of Socrates by hemlock. In the very improbable event of Mr. Passager's Bill becoming law in Indiana, will the process be called "toxication?"

SHORT ITEMS AND PERSONALITIES.

As part of the scheme which is still under consideration for improving the conditions of service in the Jail Department, the Government of India have ruled that Commissioned Medical Officers who elect to serve in that department shall be given the option of reverting from it at any time within the first two years of their service in it. It is hoped that this concession will tend to remove any reluctance to join the Jail Department which may be due to the fact that, under existing orders, a first decision to join it cannot be reconsidered.

In view of the inconvenience which has resulted to the civil medical administration from the demands made for medical officers for the China Expedition, instructions have been issued by the Government of India for the preparation of a list of stations at which two military medical charges could be held by one officer. The object in view is a readjustment of the shortage, resulting from future mobilization of troops for field service, between the Civil and Military Medical Departments.

The following is a list of the present medical members of the Bombay Corporation :—

Sir Balchandra Krishna ; Lt.-Colonel H. P. Dimmock ; Dr. N. N. Karak ; Dr. Cowasjee Hormusjee ; Dr. A. G. Viegas ; Dr. E. F. Underwood ; Dr. D. A. D'Monte ; Dr. D. M. D'Silva ; Dr. D. B. Master ; Dr. Ismail Jan Mahomed ; Dr. C. E. Dadachanji.

In his report to the Secretary to the Director-General, Indian Medical Service, Dr. Alfred Lingard, M.B., M.S., D.Ph., describes that the inoculation of cattle, either with the protective serum and virulent rinderpest blood, called *Serum-Simultaneous method*, or with serum alone, according to the circumstances of the disease, affords permanent immunity to cattle from attacks of rinderpest.

His friends, who have been so anxiously concerned about the serious illness of Military Assistant Surgeon Du'Bois, will be pleased to learn that he is now convalescent and is making satisfactory progress towards recovery in the Presidency General Hospital, Calcutta.

*It has been settled by the Nizam's Government that Colonel Gimlette, I.M.S., who succeeds Colonel Lawrie, I.M.S., as Residency Surgeon, will also be in charge of the Nizam's Medical Department, and draw full allowances.

Government have sanctioned the grant of leave to officers of the I. M. S., in either military or civil employ, to the extent that officers can be made available to replace absentees.

The special rates of mileage allowance admissible in Assam and Quetta are extended to Hospital Assistants in Burma on transfer from one station to another.

It is probable that Colonel Braufoot, I. M. S., now in Burma, will succeed Colonel McGann, I. M. S., as Principal Medical Officer at Bangalore.

Military Assistant Surgeon A. Beale, I. S. M. D., is transferred from plague duty, Bussire, to military duty, Sind District, with effect from the 25th February 1901.

The services of Major Davies, R.A.M.C., have been recommended for another year as sanitary expert at Army Headquarters.

Colonel J. T. McGann, I. M. S., Principal Medical Officer, Bangalore, has proceeded to England on furlough.

Lieutenant Boulton, I.M.S., with two Hospital Assistants, has been ordered on field service in Somaliland.

Current Medical Literature.

MEDICINE.

Acute Dilatation of the Heart in Diphtheria, Influenza, and Rheumatic Fever.

D. B. LEES (*British Medical Journal*) gives the following clinical indications in cardiac degeneration so often resulting from diphtheria: (1) Feebleness of the pulse wave. (2) Feebleness and diffusion of the cardiac impulse. (3) Extension of the cardiac dulness to the left. (4) Feebleness of the first sound at the apex, with accentuation of the pulmonary second sound. (5) A marked accentuation of the aortic second sound. The heart should be carefully examined, especially by palpation and percussion. Light percussion easily reveals the heart's limits. The virulence of diphtheria is more intense in children than in adults. Herein is the marked contrast to the behavior of influenza, which is far more dangerous to adults. In influenza rapid dilatation of the heart frequently occurs within a day or two after the onset of the disease. In rheumatic fever, even in the most subacute attacks, acute dilatation of the heart seems to be invariably present. It is much less dangerous than that of diphtheria or of influenza, in spite of its greater frequency, this difference depending upon the different effect of the several toxins upon the cardiac muscle. In fatal cases of diphtheria and of rheumatic myocarditis and fatty degeneration, or even destruction of cardiac muscle, are often found; probably similar lesions exist in influenza.

Heredity in Diabetes Mellitus, with a Report of Six Cases occurring in a Family.

J. HALL PLEASANTS makes this report, and observes certain peculiar features of the family type of the disease, as follows: (1) The occurrence of the disease in an uncle, aunt, or cousin, while the parents escape, is very often observed. This may be conveniently spoken of as the "collateral inheritance" of diabetes. In the same way a grandparent may be diabetic, while the parent escapes. (2) When successive generations are affected, there is a tendency for the disease to develop at a progressively earlier age. (3) When more than two members in the same generation are diabetic, there is a tendency for the disease to appear at approximately the same period of life. (4) While hereditary diabetes developing in the first two decades is often of a severe character, the cases developing later in life are generally of a mild type. (5) In a certain number of cases the disease has appeared in the children prior to its occurrence in the parents. (6) There is frequently a neuropathic tendency in diabetic families. Cases are recorded in which several children were diabetic, while the others suffered from various psychoses. (7) Obesity is often a characteristic of families in which diabetes occurs.

Cure of a Case of Hypertrophic Alcoholic Cirrhosis of the Liver.

M. LUZZATTO (*New York Medical Record*) reports a true case of hypertrophic cirrhosis of the liver due to alcoholism in a man fifty-five years of age, who was entirely cured with milk, potassium iodide and diuretics. The writer says the cure probably depended upon the regeneration of the damaged cells of the liver. He also states that alcoholism is by no means the only cause of cirrhosis of the liver, and that alcoholic cirrhosis of the liver is curable; the hypertrophic form more often, but the atrophic form also.

Arterio-sclerosis: its Clinical Aspect, Symptoms, Course, and Treatment.

J. W. RUNNERS says that the heart is the chief organ affected by this disease. He divides the disorders caused by arterio-sclerosis into three chief classes: (1) Syphilitic sclerosis attacking the large and medium-sized arteries, characterized by intense local symptoms, without general circulatory disorders; (2) sclerosis of the type of granular atrophy (arterio-capillary fibrosis), a general affection of the small arteries and capillaries, characterized by slight local symptoms, but by serious general circulatory disturbances; (3) the sclerosis of old age, a general affection of the large and medium-sized arteries, characterized by mixed symptoms of the various organs and disorders of the general circulation. These three varieties may be found combined.

Treatment of Epilepsy in its Inciency.

DR. W. P. SPATLING, (*Buffalo Medical Journal*) lays down certain broad principles which he summarizes as follows:—

1. Make an early differentiation of the type of epilepsy from which the patient is suffering.
2. If it be reflex epilepsy, or if the child be suffering from epileptic phenomena, the chances of cure are much greater than if the case be one of genuine epilepsy.
3. If genuine epilepsy be present, we are in a position to give a much more accurate prognosis as to the ultimate outcome, and to apply better principles in the treatment of the case.
4. Remove, as far as possible, parental sympathy from the treatment of the child, for if allowed to assert its way, this usually does more harm to the child than good.
5. Endeavor to keep from the young epileptic the many patent nostrums that, when taken by him, only aggravate the disease by first masking the true symptoms of the same; second by destroying or impairing the functions of the gastro-intestinal tract.
6. If the seizures be localized and a given part of the body chiefly involved at the time of convulsive phenomena, and suffers therefore exhaustion or partial paralysis as the result of the same, apply physical means for its correction as soon as possible, for it will only be by these means that such a difficulty can be overcome.
7. We must learn to place great value on little things in studying the etiology and treatment of this obstinate malady, and in illustration of this point let me say that it was my pleasure, in January of the present year, to see in the Pathological Museum in Berlin, under direction of Dr. RUDOLPH VISCOW, six cases in which the hæmorrhage had occurred in capillary form in the brain. Dr. VISCOW, without the use of any magnifying power, had no difficulty in locating the seats of these minute hæmorrhages. He told me that these small hæmorrhages, with their results, had caused death.

Two weeks later I saw Dr. HUGHLINGS-JACKSON in London, and I asked him what, in his opinion, would be ultimately found to be the cause of perhaps the larger number of the so-called cases of idiopathic epilepsy. His reply was that they would be found to be due to capillary hæmorrhage in the brain, followed by the minute spots of softening. I at once associated what I had seen on the *post-mortem* table in Berlin with the remarks of Dr. JACKSON, and my regard for small things in medicine grew a hundredfold.

SURGERY.

Some Considerations regarding Sympathetic Ophthalmia.

J. SANTOS FERNANDEZ (*Cronica Medico-Quirurgica, Havana*) presents 17 cases in which sympathetic ophthalmia was suspected with more or less foundation. He recognizes that in few cases the symptomatic cycle is so complete as to authorize the positive diagnosis of the affection, and undertakes to show the difficulties which beset the practice of ophthalmology, and which occasionally intervene from the timidity of patients. In four of the individuals there was no traumatism, and although enucleation was advised from fear of sympathetic ophthalmia, the staphyloma, iritis, or panophthalmitis was cured by appropriate remedies in three without enucleation, while in one operation was done to overcome pain. Non-operative traumatism existed in five cases in the primarily affected eye. In these it was that the typical symptoms always seen in sympathetic ophthalmia were encountered. In the remainder the traumatism were operative (extraction of cataract), and in these occasionally one could confirm, without ground for doubt, the remote sympathetic influence of syphilis, rheumatism, or some accidental affection; from all of which it is deducted that enucleation may always be practiced to relieve suffering and prevent loss of time to the patient, but that, when there is no previous traumatism or painful inflammatory symptom in the damaged eye, we cannot affirm that we perform the operation to combat possible or declared sympathetic ophthalmia.

New Theory in Regard to Concussion of the Brain.

D. B. BONOALI sums up his article as follows: (1) In grave cases of concussion speedily becoming fatal, the shock to the cells of the cerebrospinal axis and of the bulb causes so great a molecular disturbance that the individual neurons become incapable of regulating the nutritive and dynamic exchanges, which results in a suspension of the nutritive and secretory functions, causing violent death of the neurons from lack of nourishment and from intoxication, and for this reason there is complete absence of any lesion in the nerve tissue. (2) In cases of concussion in which recovery occurs in a few hours or days, and in which the nerve cells show the lesions described by observers, there is a transitory suspension of the nutritive and dynamic exchanges with temporary suspension of nourishment, and a transitory intoxication. The neurons appear to be in lethargy; their cellular body is shrunken, and there is retraction of the prolongations and fusion of the chromatic substances. According to the author's theory, with retraction of the protoplasmic prolongations there comes absence of nerve-protoplasmic contact and contact between the individual neurons; conduction of impulses to or from the cells is prevented, and nerve waves are impossible, the results being a temporary suspension of the vital functions.—*R. Pollicinico.*

Surgery of Hydatid Cysts of the Liver.

JOHNESCO, of Bucharest, summarizes the operations practiced for hydatid cyst as follows: (1) Puncture, which may or may not be followed by parasiticide injections—a

means of treatment which is mentioned merely to be condemned. (2) Marsupialisation; this is an operation of necessity in the case of suppurating cysts, and in those in which calcification of the wall does not allow of resection. (3) Incision followed by evacuation and suture of the cyst; the cyst, after being emptied of its contents and germinal membrane, is sutured, and the pouch left is neither drained nor fixed to the abdominal wall. This is the usual procedure followed by JOHNESCO. (4) Enucleation and extirpation of the cyst, although the ideal plan is seldom applicable.

Operations without Contact of the Fingers.

KERNIG says:—The problem of how to render the hands aseptic is solved by one word, "Don't." He has become convinced that all methods of sterilization are unreliable, and that the only means to insure absolute asepsis is to avoid direct contact of the tissues with the fingers. With the exception of abdominal surgery, he finds that instruments can take the place of the fingers in nearly all operations. The handles must be made longer than at present, and the number of retractors, etc., multiplied. With practice it becomes easy to work without direct digital contact, and to train the assistants in the same technique. If it is necessary to compress a vessel, for example, the assistant should first wrap his finger in sterile gauze.

Indications for Opening the Mastoid Abscess in Purulent Otitis Media.

MACLEWEN (*Transactions International Otological Congress*) believes the mastoid should be opened: (1) In all cases of long-standing purulent otitis media, even though the patient is but little annoyed, because the danger of further complications is great. (2) In such cases as have lesions in the middle ear, which, though they could be removed by way of the external ear, can be removed with greater safety by way of the mastoid. Removal by way of the external ear is very apt to rekindle a smouldering point of infection. This applies particularly to a so-called "aural polyp." (3) For the removal of necrotic bone, this being the only way the germs of infection can be eradicated. (4) Recurrent cases of purulent otitis media should be treated by this operation, and thus the danger of future complications be avoided. (5) Cholesteatoma and tuberculous processes with secondary pyogenic involvement should be treated by opening the mastoid, for only in this way can the diseased tissue be removed. (6) The author likens purulent otitis media to appendicitis, and says an early and complete operation is the best procedure in either case. It is the only procedure in which there is a cure. (7) It may be necessary to open the mastoid to identify the suppurative organisms, in order to determine the character of the disease. (8) Opening of the mastoid should always be done as a preliminary step to any operation upon an intracranial lesion having its origin in purulent otitis media, abscess of the brain, of cerebellum, and sigmoid sinus thrombosis. (9) It is the safest and surest way of eradicating persistent purulent otitis media.

OBSTETRICS AND GYNECOLOGY.

Heart Disease and Pregnancy.

THE dangers of cardiac disorders in pregnancy are always obvious, but there are two possibilities: (1) Pregnancy is apt to re-light an old endocardial inflammation, and the more recent the original attack, the greater the danger. (2) Dangers from pregnancy affect women suffering from cardiac disease in proportion in which old pregnancy follows another. In a case of compensated valvular disease we rarely see failure in this respect in the first four months, but where compensation did not previously exist it is not likely to occur early in the pregnancy. The rational treatment in such cases is abortion, for a viable child is hardly to be expected, and it would be folly to add to the overburdened heart the strain of useless pregnancy. In the second class, the author includes the cases where lost compensation occurs in the last half of pregnancy, and from great increase of the work of the heart the strain increases from day to day. Sometimes the failure is due to re-lighting of an old endocardial inflammation. When left to nature the chances are that the woman will not go to term. The question arises whether we should try to carry the mother past the seventh month, and if by the use of cardiac tonics the circulation can be restored, we may be justified in waiting. Gillespie does not feel certain of the advisability of this course, but is not certain of the contrary. As a heart tonic, theoretically the therapeutic action of strophanthus is preferable to digitalis, and is safer. Strychnia also produces good effects. The bowels should be looked after and absolute quiet insured, as exercise does not help the matter. If the condition of the heart does not improve and hyperæmia of the liver manifests itself and digestion is disturbed, and especially if the urine shows albumin with casts, medical treatment is useless. Whenever labor occurs, whether early or late, it must be conducted so as to incur as little strain as possible, and he does not think that anaesthetics are contraindicated by cardiac disease. The usual methods will not suffice in induced labor. Rapid manual dilatation and extraction by the feet is the safest, as being the least exhaustive, and also offers the best possibilities of delivering a living child. The hydrostatic bags are applicable in many cases. A case is reported illustrating the points made in the paper. The author concludes that it is not safe to wait for development of the heart symptoms. They should be anticipated, and in every case where the heart is in ill-health, forceps delivery is advisable as soon as compatible with other conditions.—*Jour. Amer. Med. Assoc.*

Two Advantages Ovary possesses over Curettage.

THE advantages FRANK A. STAHL, M.D., mentions are:—

1. The superior advantage of the finger in recognising foreign bodies.
2. The superior shelling out intact of the secundines. Advantage of the finger, instead of the usual morselling by the curette and forceps.

The following additional points were referred to by others during the discussion:—

3. Danger of perforation with the curette.

4. The finger can determine the exact location of the secundines, and we naturally curette the part to which the secundines are attached; whereas, when we use the curette, we are apt to curette the whole mucosa, which in septic cases is dangerous, and in non-septic cases uncalled for.

Of the seven gentlemen who discussed the paper, only one favoured the curette.

Suprapubic vs. Vaginal Section.

BENJAMIN (*Journal of the American Medical Association*) insists on the greater advantage of performing abdominal section over the infrapubic operation, and quotes a number of authorities in support of his view. The chief advantage is the ability to make a more thorough operation, to discover complicating conditions, and to meet the complications. He offers in conclusion the following as suggestions in regard to the matter: (1) The abdominal operator has the advantage of sight, touch and access to the disease. (2) He is able to explore the whole abdomen for visceral disease. (3) He can do careful, complete and conservative work. (4) There are few diseases of the female pelvis, except certain abscesses, operable from below that are not best treated from above. (5) Surgery of the female pelvis should be the practicing of good surgical sense, and not fads.

Sexual Feeling and Removal of Ovaries.

IN the case reported by SMITH there were misplaced and inflamed ovaries causing the patient misery, with complete absence of sexual feeling. The ovaries were removed, as the patient had been under medical treatment for years without benefit. The result was restoration to health and complete restoration of sexual feeling, which had heretofore been absolutely absent. The cure seems to be permanent, and he agrees with LAWSON TAIT that in cases of useless and diseased ovaries the removal of the diseased structure restores the normal conditions, and does not unsex the woman.—*Jour. Amer. Med. Assoc.*

Organotherapy in Gynecological Therapeutics.

JACK (*International Journal of Surgery*) draws the following conclusions from his experiments and the study of the literature: Thyroid extracts is one of our most reliable vasoconstrictors, and as far as its gynecological application is concerned, should be limited to hæmorrhages, and those especially in which the epithelial elements of the endometrium are concerned. Mammary extract controls the hæmorrhages from fibromas, reduces the size of the tumors, and in some cases causes their disappearance, and should be preferred to the thyroid extract, which does the same thing in treating fibromas. Parotid extract is the best remedy yet brought out in the treatment of dysmenorrhœa, relieving, as it does, the aches and pains of ovaritis and improving nutrition. Pelvic exudates soften and are often absorbed. Menstruation becomes regular and less in amount when excessive and shorter in duration. The headaches and nervousness so often accompanying these cases are as a rule cured, health and spirits revive, and, indeed, its action here can be denominated nothing less than specific. Ovarian extract is indicated in all cases of menopausal nervous symptoms, or when for any reason it is desirable to increase the flow from the uterus. It is now known almost beyond doubt that the ovary has, besides its function of ovulation, another almost as important, that of internal secretion, and that, like the thyroid, it secretes an active oxidizing agent—spermin—that aids in the metabolism of the blood. Marked decrease in the elimination of phosphates has been observed after ovariectomy.

PHYSIOLOGY, PATHOLOGY, AND BACTERIOLOGY.

Bacteriætal Power and the Alkalinity of the Blood in Leucocytosis from Intoxication by Mineral Poisons.

A. BENTIVEGNA and F. CARINI, from the results of experimentation, conclude that the presence of leucocytes in cases of mineral poisoning has the same biological significance as that attributed to it in bacterial intoxications and infections, and that the mechanism of defence of the organism acts against mineral toxic substances with the same energies that up to the present time have been considered a special manifestation in the case of bacteria and microbic toxins.—*Lo Sperimentale*.

Abdominal Relaxation a Probable Factor in the Pathogenesis of Gall-Stones.

JESSE S. MEYER concludes that: (1) Visceral ptosis, consequent upon abdominal relaxation and other causes, results in stagnation of the bile through interference with its normal expulsion. (2) The inactivity of the gall-bladder and stagnation of the bile predispose the mucous membrane to infection. (3) This infection may be either hæmatogenic through the portal system, etc., or an ascending infection from the duodenum. (4) This results in a catarrhal inflammation of the mucous membrane, an albuminous exudate, and the exfoliation of epithelial cells. (According to NAUMY, the addition of albumin to the bile produces a copious precipitation of the stone-forming elements.) (5) This precipitate, with clumped bacteria and degenerated cell masses as nuclei, forms biliary calculi.—*St. Louis Medical Review*.

Production of Jaundice.

THE author's conclusions regarding the production of jaundice are: (1) The basis of jaundice is an increased function of normal liver-cells, which, excited by different stimuli, produce more bile or bile-pigment. (2) Only a normal liver-cell which can take up and elaborate an excess of nutriment, and thus can produce an increased quantity of bile, can eliminate this excess of bile into the intercellular bile-passages, whence part of the bile passes into the blood; in part directly through the walls of the blood-capillaries. (3) The mechanic factor has only an indirect influence, in that it disturbs the intravenous circulation in the blood-capillaries. (4) The bile reaches the general circulation through the blood-capillaries of the hepatic veins, and only to a slight extent through the lymphatics of the larger bile-channels. (5) All forms of icterus can be explained in the way designated, viz. on an increased functional activity of the liver-cells, which means an over-production of bile or bile-pigment.—*Phil. Med. Jour.*

Bacteriology of the Stomach.

KELLOGG's article reports the findings of bacteriologic examinations of the stomach fluid in various conditions, and his conclusions are summarized as follows: (1) A healthy stomach does not require the aid of germs in the digestion of foods. (2) Sterile food is digested in the healthy stomach without the development of bacteria or other micro-organisms. (3) Neither free hydrochloric acid nor combined chlorin, even when present in excess, is a certain means of sterilizing the gastric contents. (4) The gastric contents may be found sterile after a sterile test meal in bases in which free hydrochloric acid is entirely absent and the proportion of combined chlorin small. (5) Fruits, especially fresh fruits, and fruit juices, are capable of completely sterilizing the stomach when used in sufficient quantity.—*Jour. Amer. Med. Assoc.*

Localization of Leprosy Bacilli in Various Organs.

M. JEANSELINE, in concluding his elaborate paper, says that the bacteriologic diagnosis of every case of leprosy should always be made in the interest of the community as well as of the patient. The nasal mucous may contain the bacilli in the early stages of the tubercular or maculo-anæsthetic forms of the disease. The saliva, the tears or other secretions may show them. The semen, the vaginal secretion, the faeces even, may be virulent evokers of the disease, but the urine is free from leprosy bacilli. Prophylaxis then consists in rigid disinfection of the nose and skin of leprosy persons, and the perfect occlusion of all ulcerations. All objects of common usage, such as the clothing, should also be rigorously cleansed.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Mental Sanitation.

SMITH (*The Canadian Journal of Medicine and Surgery*) calls attention to the marked influence which heredity has in producing insanity, and charges that much of the so-called literature of the present day conduces to an unsettled mental state. He concludes as follows: (1) The public should be enlightened with regard to the nature of insanity in order that they may properly estimate the influence of heredity as the most potent factor in the causation of disease. (2) As a preventive measure the public should be taught that as the development of the morbid disposition is most insidious and is seldom recognized until late, the consideration of the family and personal history of the individual should demand and receive early and careful attention. (3) There must be full recognition of the invariability of individuals for bearing burdens and enduring strains. (4) Many cases of insanity are justly chargeable to the imposition of burdens beyond the capability of the individual. (5) The prevention of insanity is not promoted by merely studying the phenomena of the disease. (6) Public sentiment must be enlightened before any restrictive measures can be beneficially enforced. (7) If the conditions under which many cases of insanity originate were properly understood, many attacks of the disease might be avoided. (8) The study of child character and the careful consideration of the variability in the development of mental phenomena during the period of growth in the child are all important. (9) The steps necessary to secure the adoption of these and all other precautionary measures must first be taken by the family physician, who in the future must be prepared to advise, caution and restrain in exercising his influence in the prevention of mental disease. (10) The burden must be adjusted to the capacity of the individual in order that it can always be carried with safety when this is possible; and when it is not possible, that the line of descent of every such defection shall terminate with the individual himself.

Uses for Lemons.

No family should be without lemons. Their uses are almost too many for enumeration.

The juice of a lemon, taken in hot water on waking in the morning, is an excellent liver corrective, and for stout women is better than any anti-fat medicine ever invented.

Glycerine and lemon-juice, half and half, on a bit of absorbent cotton, is the best thing in the world wherewith to moisten the lips and tongue of a fever-parched patient.

A dash of lemon juice in plain water is an excellent tooth-wash. It not only removes tartar, but sweetens the breath.

A teaspoonful of the juice in a small cup of black coffee will almost certainly relieve a bilious headache.

The finest of manure acids is made by putting a teaspoonful of lemon-juice in a cupful of warm water. This removes most stains from the fingers and nails, and loosens the cuticle more satisfactorily than can be done by the use of a sharp instrument.

Lemon-juice and salt will remove rust stains from linen without injury to the fabric. Wet the stains with the mixture and put the article in the sun. Two or three applications may be necessary if the stain is of long standing, but the remedy never fails.

Lemon-juice (outward application) will allay the irritation caused by the bites of gnats or flies.

Lemon peel (and also orange) should be all saved and dried. They are a capital substitute for kindling wood. A handful will revive a dying fire.

Two or three slices of lemon in a cup of strong tea will cure a nervous headache.

Lemon-juice removes stains from the hands.

The natives of India clean brass trays, Indian and Moorish brass work, pipe stands, and all such things with a cut lemon. Wipe afterwards with a leather.

Fill a wide-mouthed pint bottle half full of brandy, and whenever you have bits of waste lemon rind, pare the yellow part thin, and drop it into the bottle. A few drops make an excellent flavouring for tarts, custards, blancmanges, &c.

At what Age should Girls marry?

THIS question is discussed by various lady writers in *The Young Woman*. JOHN STRANGE WINTER believes in early marriages—provided, of course, that the girl marries the right man. "I think," he writes, "that everything tells for an early marriage, and nothing can be reasonably urged against it. We are accustomed to hear a good deal of the enjoyment of youth. We are told by some people that it is a pity to curtail girlhood. Well, now, what is there about girlhood that it is a pity to curtail it? It is a period of probation; it is a time when a girl is on her promotion; it is a half life at best. I think that when a girl marries young—that is, from eighteen to twenty-five—according to her temperament and her opportunities, and always supposing that she marries a husband whose age is really contemporary with her own, she has a better chance of bringing healthy children into the world. If she waits eight or ten years, she will marry a man eight or ten years older than the husband she would have chosen in her youth. She gains nothing by that; on the contrary she gives up, it is true, a few pleasures—or say, she may have to give up a few pleasures—for what does the English girl enjoy that the young married woman is shut out from? She takes certain responsibilities upon herself. After all, they are natural responsibilities, and will come no easier to her in ten years' time, quite otherwise. Then there is another argument in favour of early marriages; it is that mother and children will be young together.

Mrs. BOYD CARPENTER (the wife of the Bishop of Ripon) thinks it cannot be wise or right for a girl to marry until a certain maturity of character has been reached. "For what does marriage mean?" she continues: "The gaining of freedom, the direction of a household, the spending of an income, the maintenance of a position, the life of enjoyment, the change from a position of comparative insignificance to one of authority. Ay, and more than that. It is the fruition of life, and not until the plant has reached maturity should there be blossom and fruit. The seed time in the home, the growth and development at school and at college and in society, these are the preparation. Then comes the blossom, when the receptive period becomes the productive; when from being a learner the girl becomes an actor; when she takes up life for herself and realises her own responsibility of existence. This is the period before which she should not marry, but after which, if she wishes, she may do so safely and happily. For what is marriage? The linking of two lives for good or for ill, the conscious and continuous exercise of influence upwards or downwards; and, if the heritage of children is theirs, the instilling of principles and the formation of characters which will bear fruit in the ages to follow. To the girl who takes a high view of life and its possibilities, who is not satisfied with a butterfly existence of empty pleasure, marriage will be too serious a step to be undertaken lightly or unadvisedly, and therefore she will not be unhappy if she leaves her teens behind before she steps into the dignity of a married woman."

Signs of Death.

SYNCOPE, coma, concussion, hysterical spasm, catalepsy and exhaustion may simulate death, although in these conditions the body warmth is retained and the heart and lung action continue, but feebly perhaps. The signs on which a medical man should rely as furnishing the best evidence of the reality of death, prior to the commencement of putrefactive changes, are:—

1. The absence of circulation and respiration.
2. The gradual cooling of the body, the extremities cooling first and the trunk last.
3. Gradual supervention of rigor mortis.
4. The production of *post-mortem* stains or ecchymoses.

The careful observation of these four signs by a medical man will enable him to distinguish a living from a dead body.—*Brit. Med. Jour.*

THERAPEUTICS & PHARMACOLOGY.

Experimental Medicinal Cure of Gall-Stone.

N. D. TITOFF says a Test on nine large dogs are described in which the gall-bladder was incised and one or two human cholesterol calculi inserted. The wound was then closed and efforts made to dissolve the calculi by medicinal measures. They were successful beyond anticipation. If confirmed by future experience, the fact is established that gall-stones can be artificially dissolved by way of the intestinal and biliary passages. Three Pravaz syringefuls of a mixture of one part ether to two parts benzol were injected per rectum. The injections were well retained and no local nor general unfavourable symptoms were observed. Traces of cholesterol crystals could be found in the bile aspirated even as soon as a half hour afterward. The stone had lost 16.6 mg. in weight when the animal died, two weeks after these injections had been inaugurated, in one case. These experiments demonstrate that the medicinal treatment of gall-stones has a solid foundation, and that the only problem is to administer the benzol or other dissolvent in the least irritating form, possibly as terpin hydrate with euobinin or turpentine and quinine. In some of the experiments no medicine was used, but the stone diminished .013 to .01545 mg. The chloroform given during the operation may have been responsible in one case, but in the other no chloroform was used. This result seems to indicate that the natural bile of dogs is able to dissolve cholesterol calculi in certain cases at least.—*Jour. Amer. Med. Assoc.*

Treatment of Typhoid Fever by Enemata of Olive Oil.

OWEN F. PAGET, M.B., B.C. (*Lancet*) has previously advocated the following treatment:—It consists in slowly administering every 12 or 14 hours an enema of about a pint of olive oil. The oil should, if possible, be retained in the bowels 12 to 14 hours. If it is not returned after this time, it may be brought away with an ordinary soap-and-water injection, a fresh dose of olive oil being administered two or three hours later. After a week or ten days the daily injections are discontinued, and they are given only when the temperature rises or the bowels are confined. With diarrhoea it is imperative to give olive oil; it is more efficient than opium or any other drug in bringing about natural evacuations. Occasional small doses of calomel from $\frac{1}{10}$ gr. to $\frac{1}{2}$ gr. are useful if the oil is not sufficiently stimulating to make the bowels act. With oil injections bismuth preparations are quite unnecessary.

Patients treated in the above manner, according to the writer, never die. He believes that typhoid fever *per se* is harmless, that it is the accompanying sepsæmia or ptomaine poisoning which produces the ill-effects. Under this treatment there are no sequelæ, tympanites, perforation, or heart failure. No cold baths are necessary.

Chloral and Hæmorrhage.

A. MODEL ascribes a series of very severe hæmorrhages from the stomach, lungs, intestine, and nose, which he himself suffered from, to the habitual use of chloral as a hypnotic. Before the use of the drug was begun, in spite of a hæmophilic family history, no bleedings ever occurred; after it had been taken for some time, the hæmorrhages were frequent, but again were conspicuous by their absence during a period of four years of chloral abstinence. Finally, at the end of this time, moderate indulgence in the drug was followed by a recurrence of the bleeding.

On the Use and Abuse of Lavage.

JOHN HERR MUSSER believes it unwise to allow patients themselves to do lavage; soon a habit develops in them, which is apt to prove injurious. Every ache or sense of distress, every eructation or heartburn, invites the use of the tube. The writer uses it in cases of a tonic dilatation, when the retention is extreme; in cases of organic pyloric obstruction; in gastric neurasthenia and certain cases of hysteria, and in some cases of chronic gastritis with sub-acidity. To ascertain the nature of any gastric lesion or disorder, he makes a practice of analysing the stomach contents of all patients whose complaints are gastric, and all whose general health suggests imperfect nutrition from defective gastro-intestinal processes. He also employs physical means for determining the size of the stomach—percussion, inflation, etc.—*The Therapeutic Gazette*.

Palatable Effervescent Quinine.

Syrupi simplicis, q.s.	ad. 3v.

M. Sig. One tablespoonful every hour until relieved.

H. KLEIN, of Chicago, states that he was successful in checking the hiccough in a patient, which had continued for four days, by the administration of two doses of the above preparation.

*Correspondence.*THE NEW PRESIDENCY GENERAL HOSPITAL,
CALCUTTA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—The following from *Indian Engineering* will interest your readers:—

"It is seldom that one can write in unqualified praise on the construction and sanitary arrangements of even a new building. The new European General Hospital has evidently had the greatest care and the best skill bestowed upon it, and the result is a building which is not only structurally adapted in the highest degree for the purposes in view, but is in its sanitary arrangements about as perfect as it is possible to be. It consists of a central block, chiefly taken up by administrative offices and private wards, with large rectangular ward blocks on each side. These latter contain six main wards, two on each floor, and each has accommodation for 24 patients. At each end of the building are the lavatories. The whole structure is raised eight feet above the ground on a series of pillars allowing a free air space below the ground floor. The hospital faces north and south, because the prevailing winds are from the south. With the exception of the central end, a wide verandah runs round each of the main wards. The roof is flat, and affords a most excellent promenade extending over the whole building. The wards are arranged so that 116 superficial square feet and 1,914 cubic feet capacity will be allowed for each patient.

This is a liberal allowance, taking into consideration the free perfusion of air provided for—in fact, the atmosphere of the ward can hardly fall short of the purity of the external air. Every thought has been bestowed to prevent the lodgment of dust and dirt. The floors of the wards and some of the other rooms are paved with marble. The remaining floors, including the verandahs, are finished with Indian patent stone, which has proved such a boon in Calcutta. The work in this case has been carried out with extra special care, and the results are very gratifying. The dadoes of the wards and other rooms are faced with white glazed tiles to a height of five feet. There is a channel drain all round each ward close to the wall and opening out on to the verandah. The windows are carried close up to the ceiling. The lavatories and ward closets for each ward occupy the small isolated wings at the east and west extremities of the building. The medical officer's room and the nurse's room overlook each ward. In addition to the verandah there is a day room for the patients of each ward, to which are also attached a linen room and scullery with an isolated sink room for washing up. There are also two small separation wards in connection with each main ward. The central block contains six private wards on each storey. These have their own lavatory blocks, also a day room on each floor, with pantry and store room and a south verandah. These wards contain one and two beds, and are intended for the lower grade paying patients, who will not be prepared to indulge in the more superior accommodation and board contemplated in the future Paying Patients' Block. The two operating rooms, one above the other, are beautifully situated over the central porch. They face north, and are also open to the east and west, and each has an anæsthetic room and a splint and bandage room close by. So much for the general structural arrangements.

We must now consider the sanitary fittings. The sewage of the hospital will drain into the Circular Road. There is sufficient fall and an intercepting tank is provided near the main sewer. Within the grounds there is an inspection chamber at every 75 feet. The soil pipes

are glass-lined and well ventilated, and wherever a band has been necessary a screw-down inspection flap has been provided. Each closet drains separately into the soil pipe of its block. An ingenious cowl, insuring an up-draught of air, is fitted to the top of each ventilating shaft. The ward W. C.s are fitted with FINCH'S "the Asylum" pan—a wash-down form of closet, fulfilling the most modern requirements. There are also SHANK'S patent slop sink and bed-pan washer—the latter an ingenious method of cleaning these articles without risk of soiling the hands. There are some curious cages placed on the widow sill outside the lavatories for putting the bed-pans in after washing, but these strike us as being quite unnecessary. Each W. C. has its own little cistern, and in case of repairs provision has been made for cutting off each individual supply. The plumber's work looks everywhere to be particularly good, and has been done by English labour. The water-supply is entirely of filtered water, and comes from the main into an underground reservoir. This will contain about 10,000 gallons, or roughly two days' supply. From this the water is pumped by electrical power to the eight large cisterns at the top of the building. From two of these cisterns water is taken solely for drinking purposes, so that there is no danger of the drinking supply becoming contaminated from the supply which is distributed to the lavatories. Each tank moreover can be shut off whenever necessary. The whole building has therefore two sets of pipes for its cold-water supply. In addition, there is the hot water system of pipes which branch off from the boiler situated in the basement. This is arranged with a double set of pipes, allowing for a specially free circulation of the heated water. A great feature of all the water-supply pipes in the building consists in their being blocked off the wall. This advantage is applied also to the large rain-water pipes run down the outer walls on their inside, facing the verandahs, and the washings of the verandah floors enter these pipes with branch connections. We think this arrangement is a distinct improvement, and there is no objection to it on sanitary principles.

The sanitary construction and fittings of the operation rooms are on the latest models. The floors are of marble and slope to an outlet channel drain at one of the outer corners, so that the floor washing is carried outside. The walls are tiled five feet up, and every angle or ledge is bevelled off for ready cleaning and for preventing the lodgment of dust. There is fitted a MORRISON INGRAM'S Sink with treadle action for water-waste and for hot and cold water supply, and a SHANK'S Projector wash basin with treadle action supply and knee action for water-waste, together with spray and douche handle. There are the requirements of modern ingenuity for saving labour, and in the carrying out of this department of work it is impossible to award too great praise to that well-known firm, Messrs. J. B. NORTON and Sons, for the high standard of plumbing they have put into this building. Several gentlemen well-versed in plumbing matters, and who have taken stock recently of corresponding work done in England, acknowledge in Messrs. J. B. NORTON and Sons' handiwork at the hospital something that will compare most favourably with anything of the kind done elsewhere. The firm in question, the Architect and Engineers and the Medical authorities have reason to be specially proud and satisfied that the sanitary needs have been so carefully thought out and executed.

The lighting, which will be by electricity, is in the hands of Messrs. BALMER, LAWRIE and Co., and electricity will also be the motive power for the punkahs, pumps, etc. In carrying out the lighting, this firm has succeeded in executing work of a high class, and the Government Electrical Engineer's tests and report are exceedingly satisfactory. The operating room lamps are a special

feature, being swivelled and pointed so as to be adjustable to any height or angle. This firm is also supplying the electric pumps, of which one is already fixed.

The nurses' quarters, consisting of a three-storeyed building near the Canning Home, is also approaching completion. It will be required for the extra staff of nurses to be employed when the new hospital is opened. The main kitchen, too, is well in hand, and is expected to be ready for use in another month or two. It contains refrigerating arrangements, steam-cooking appliances, a grill, and a bakery, besides the usual cooking ranges, etc. Wards for infectious diseases are, we understand, to be taken in hand ere long. These are necessary adjuncts, and the removal of the present building used for isolation purposes, which is in too close proximity to the new hospital, will be loudly called for when the latter is occupied.

Taken as a whole, it may without question be said that the design of the new hospital building is excellent. It is true the architecture is plain, but it is manifest that everything has been sacrificed to ensure utility and efficiency, and the architect is to be congratulated on thus realizing the public ideal. The result must be a source of satisfaction to all concerned, because it embodies the best principles of the builder's art, and fulfils the latest commands of modern sanitary science. We are unable to obtain an exact date as to when it will be ready for use, but apparently its occupation will not be delayed beyond a few weeks from now."

Yours, &c.,

P. G. H.

A TRIP THROUGH THE LABORATORIES OF FREDERICK STEARNS AND CO.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—A visit to any of the larger pharmaceutical laboratories is generally of interest to a retail druggist, but when it is one that is entirely new throughout and most modernly equipped in every way, as is that of Frederick Stearns & Co., the visit is doubly enjoyable. This firm's new home is situated in one of Detroit's most beautiful thoroughfares—Jefferson avenue, near the bridge leading to Belle Isle. The laboratory, which covers an entire city square, is built in the form of a hollow rectangle, with Jefferson avenue on the south, Bellevue avenue on the east, and the Michigan Central Belt Line on the west.

Around the open court (which affords perfect light) is a gallery on each floor. These galleries are completely enclosed in glass, and are used as a means of connecting the different buildings and departments.

At first glance this imposing structure seems to be one continuous building, but in reality there are seven separate buildings, six of which are devoted to the laboratories, and the remaining building (that fronting on Jefferson avenue) is for office purposes only. This office building is of the Elizabethan or English renaissance style, and is the handsomest of its kind in the city. Its entrance is through a beautiful stone arch, the floor of which is inlaid tiling. Entering the vestibule and passing into the main hall, one goes directly into a large reception room, which is finished in antique oak—floors, pillars and ceiling—right off from which are located three cozy little consulting rooms. On the first floor are the directors' room, the office of the Vice-President and Treasurer, Mr. F. C. McLaughlin, and in regular rotation are the offices of Mr. W. I. L. Stearns, Assistant Treasurer, Mr. W. D. Stearns, Superintendent, and Mr. W. G. Rankin, Assistant Superintendent. At the other end of the hall are located the book-keeper's office and the office

of Mr. N. A. Tabor, manager of collections and credits. On the second floor the President, Mr. F. K. Stearns, has a suite of three rooms at the south-east corner, adjoining which are the two offices of Mr. S. C. Stearns, Assistant Secretary, who is also in charge of the scientific department. Next in order come the three offices of the Secretary, Mr. Thos. Bennett, who has charge of the foreign business, then following come the offices of Mr. J. W. T. Knox, advertising manager and editor of *The New Idea*, and Dr. Yarbrough. At the end of the hall is a suite of rooms in charge of Mr. D. M. Gray, manager of the department of sales and travelling salesmen. Adjoining Mr. Gray's offices is a large room called the "travellers' room," which is at the service of the many travelling men of the house whenever they happen to be in off the road: adjoining this is the sample room. There is also a library and reading-room on this floor.

From the office building the visitor is conducted to the laboratories, which were built in the form of a rectangle, so that the material handled which enters at one gate may, after going round the whole rectangle, come out a finished product at the same gate in which it entered as crude material. It goes first into the stock building devoted wholly to the storing of drugs, chemicals and glass. The first floor (which is really a high cellar) of this stock building is devoted to the manufacture of vinous preparations, such as wine of cod liver oil, beef, iron and wine, and similar compounds. This room is concreted and is cool during the hottest summer months.

The next building contains on the first floor or cellar the plant for power, heating and lighting. Here are three new steel boilers of 100 horse-power each, an engine of 150 horse-power, and an immense dynamo. Above this is the mill room, where the crude drugs are ground or powdered by means of various appliances. Adjoining the mill room is a room devoted to the manufacture of "Kasagra," and next comes the still room containing vacuum pans, pumps, etc. The largest pan used for water evaporation has a capacity of evaporating 70 gallons an hour. In the still room in addition to the vacuum pans are found "all sorts and conditions of" stills, from the small twenty-gallon copper ether still for the making of oilo-resins up to the large steel still for recovering alcohol, which holds six hundred gallons. Here are also located several large open evaporating pans of different sizes. Passing along in regular order, one comes to the percolating room, in which are located fluid extract percolators of all sorts and sizes, from the huge wooden tapering tanks, which hold five hundred gallons for exhausting mandrake for podophyllin, down to the little glass two-gallon percolators for special work. Leaving the percolating room, one passes into the general manufacturing room, in which the special formula work and simple domestic remedies are made.

The next department in order is the packing and shipping room, but as that is nearly the last place where a drug or preparation is taken to, it is generally left until later on. Passing over then to second story west building, the guest next visits the analytical department, presided over by Prof. Sherrard. It is here that all crude drugs as well as finished preparations are assayed. Next in order comes the department of the manufacturing and putting up of cachets.

The next department in order is the label stock-room. This is a large-sized room given up entirely to the keeping of the thousands upon the thousands of assortments of the different labels made and used by this concern. Then comes the press room and printing department. Here is an array of printing machinery, the like of which does not exist in many cities even in the regular printing business, and no pharmaceutical establishment here or abroad has such great facilities for fine printing. A bindery and a paper stock room complete this department.

Moving along the gallery one comes next to the pharmaceutical finishing department, the assembly room, where are finished the private formulas, etc.; the paper box factory, which covers an area of 300 feet long and 40 feet wide and employs 70 people; the elixir or wet department, a room 100 by 40 feet; the pill finishing room, a department for making filled capsules, capseids, tablet room and drying rooms. On the fourth floor the powdered goods are put up.

In the next building is the perfume department. The perfumes are made, bottled and stored in the basement. On the next floor are the filling labelling and boxing rooms. Across the court are the packing and shipping rooms, where a most perfect system of handling orders is installed.

In this article nothing has been written about the buildings themselves, the people who inhabit them, or of the company whose business is done within them. Nor will space permit a description of the biologic laboratory, which occupies a separate building. A description of the buildings was printed in the *Era* for March 1. Frederick Stearns & Co. claim that in these new quarters they have "the most modernly constructed and perfectly equipped institution of its kind in the world."

Yours, &c.,
R. MARTIN.

BOOK REVIEW.

MANUAL OF THERAPEUTICS.

BY PARKE DAVIS & Co.

This well-bound and very neatly printed volume of 421 pages has been sent us for review. As an aid to the busy practitioner who uses the preparations of this worthy firm of pharmaceutical chemists, it is perfect; but to students and practitioners who practise according to the British Pharmacopoeia, it is practically of little value.

Government Medical Gazettes.

MADRAS.

Furlough on med. certificate, from the 9th Sept. 1899 to the 21st Dec. 1900, granted to Lieut.-Col. W. B. Browning, I.M.S., is commuted into furlough without med. certificate.

In exercise of the power conferred by Section 11 of the Madras Local Boards Act, 1884, His Excellency the Governor in Council is pleased to appt. the undermentioned gentlemen to be members of the following Dist. Boards:—

Dr. B. Sundaram, Chingleput.

Lieut.-Col. W. A. Lee, I.M.S., Trichinopoly.

Capt. W. O. Vickers, M.B. & C.M., I.M.S., Coimbatore.

N.-W. P. & OUDH.

Civil Asst. Surgn. Nil Ratan Banerji, attached to the Sadul Disp., Sultanpur, privilege leave for one month, from the 17th Feb. 1901.

Temp. Civil Asst. Surgn. Kashi Nath, on reserve duty at Benares, to plague duty at that station, from 1st Feb. 1901.

Notification No. 1275, dated 11th Feb. 1901, appointing Hosp. Asst. Narsin Prasad to the ch. of Husainabad Disp., Lucknow, is hereby cancelled.

Civil Asst. Surgn. Chanan Singh, on being relieved of plague duty in connection with Magh Mela, Allahabad, to reserve duty at Allahabad.

Civil Asst. Surgn. Ghulam Mustafa, from the ch. of Huseinabad Dispy., Lucknow, to Sadr Dispy., Musaffarnagar.
Civil Asst. Surgn. Behari Krishna Basu, attached to Sadr Dispy., Jaunpur, privilege leave from 29th Dec. 1900 to 16th Jan. 1901.

Hosp. Asst. Narain Prasad, on reserve duty, Lucknow, to the ch. of Huseinabad Dispy., Lucknow, as a tempy. measure.

Dr. H. A. Macleod, in civil med. ch. of the Ballia dist., is placed on special duty in that dist. in connection with plague.

Major B. J. Innes, B.A.M.C., Roorkee, held civil med. ch. of that stn. in addn. to his military duties from the 24th Oct. to the 24th Nov. 1900.

PUNJAB.

The following tempy. transfers were made in the Ferozepore Dist. in consequence of the grant of leave to Asst. Surgn. Kirpa Ram, Kora Fazilka Dispy. :—

Hosp. Asst. Nur-ud-din is transferred from the Abohar to the Fazilka Dispy., from the 1st Jan. 1901.

Hosp. Asst. Muhammad Usman Ghani is transferred from the Police Hosp. to the Fazilka Dispy., from the 4th Jan. 1901.

Hosp. Asst. Nur-ud-din reverted to the Abohar Dispy. on the 5th Jan. 1901.

Hosp. Asst. Imam-ud-din, Jail Hosp., Ferozepore, assumed ch. of the Police Hosp., in addn. to his duties, on the 3rd Jan. 1901.

With the sanction of Government, the following Licentiates of Medicine and Surgery of the Lahore Medical College were employed as tempy. Asst. Surgns. and posted to the stns. and from the dates noted against their names :—

Lala Jagat Narain—Sialkot, gen. duty, 26th Dec. 1900.

Lala Baghunath Sahai—Civil Hosp., Umballa, 23rd Jan. 1901.

Lala Shiv Das—Fazilka Dispy., Ferozepore Dist., 29th Jan. 1901.

Pandit Rup Narain—Delhi, gen. duty, 1st Feb. 1901.

On transfer from Amritsar, Hosp. Asst. Baber Khan was apptd. to the ch. of the Chenab Canal Dispy., Chenawan, Gujranwala Dist., on 21st Jan. 1901, relieving Hosp. Asst. Gurmukh Singh.

On transfer from Hissar, Hosp. Asst. Metab-ud-din was placed on gen. duty at Gurgaon from the 18th Jan. 1901.

Hosp. Asst. Hari Singh, Hamirpur Dispy., Kangra Dist., has obtained one month's privilege leave, and was relieved of his duties on the 19th Jan. 1901 by Hosp. Asst. Kahan Singh, transferred from Balaampur in the same dist.

On transfer from Mianwali, Bannu Dist., Hosp. Asst. Ghulam Basul was attached to the Northern Waziristan Militia Regiment, Idak, Tochi, from the 31st Dec. 1900, relieving Hosp. Asst. Chaman Lal, who was placed on gen. duty at Bannu from the 2nd Jan. 1901.

Hosp. Asst. Waryam Singh resumed ch. of the Sangla Dispy., Gujranwala Dist., on the 1st Feb. 1901, relieving Hosp. Asst. Arjan Das, who was placed on gen. duty at Gujranwala on the 3rd Feb. 1901.

Hosp. Asst. Ghulam Basul resumed ch. of the Tohana Dispy., Hissar Dist., on the 1st Feb. 1901, relieving Hosp. Asst. Brij Lal.

Hosp. Asst. Ram Chand resumed ch. of the Rawalpindi City Branch Dispy. on the 1st Feb. 1901, relieving Hosp. Asst. Jagan Nath, apptd. to do gen. duty at Rawalpindi.

Hosp. Asst. Khuda Baksh, doing gen. duty at Delhi, to the Jullunder Dist. for plague duty. He reported himself to Chief Plague Med. Offr. at Bangat on the 1st Feb. 1901.

Hosp. Asst. Bansil Lal, doing gen. duty at Jullunder, to the Gurdaspur and Sialkot Dist. for plague duty. He reported himself to the Plague Med. Offr. of those dists. on the 31st Jan. 1901.

Lieut.-Col. Z. A. Ahmed, I. M. S., assumed ch. of the Civil Med. duties of Wana on the 19th Jan. 1901, relieving Lieut. F. V. O. Beit, I. M. S.

Asst. Surgn. Khazan Chand made over ch. of the duties of 'Suptd. of the Sialkot Jail' to Capt. P. St. C. More, I. M. S., on the 12th Jan. 1901.

BURMA.

Capt. C. G. Roberts, I.S.M.D., on proceeding on six months' leave on med. certificate, made over, and Mily. Asst. Surgn. P. McCarthy, on return from leave, assumed ch. of the Civil Surgeoncy of the Tharrawaddy dist. on the 28th Jan. 1901.

Hosp. Asst. Jai Lal, on return from leave, assumed ch. at the Gen. Hosp., Rangoon, on the 6th Feb. 1901, as a supy.

Hosp. Asst. Raj Chunder Kug, on transfer to Maymyo, relinquished ch. at the Gen. Hosp., Rangoon, on the 27th Jan. 1901.

Hosp. Asst. Bishen Lal, on return from leave, assumed ch. at the Gen. Hosp., Rangoon, on the 6th Feb. 1901, as a supy.

Hosp. Asst. Bihari Lal, on return from India, assumed ch. at the Gen. Hosp., Rangoon, on the 27th Dec. 1900.

Hosp. Asst. D. Swami Dass, on return from leave, assumed ch. at the Gen. Hosp., Rangoon, on the 27th Dec. 1900.

Hosp. Asst. Kishori Mohan Majumdar, on transfer from India, assumed ch. at the Gen. Hosp., Rangoon, on the 5th Jan. 1901, as a supy.

Hosp. Asst. Radha Mohan Chakravarty, on transfer from India, assumed ch. at the Gen. Hosp., Rangoon, on the 3rd Jan. 1901, as a supernumerary.

Hosp. Asst. P. Govinda Pillay, on transfer to Rangoon, relinquished ch. of his duties as a supy at the Civil Hosp., Sandoway, on the 29th Nov. 1900, and assumed ch. at the Gen. Hosp., Rangoon, on the 3rd Dec. 1900, as a supy.

Hosp. Asst. P. Govinda Pillay relinquished ch. of supy. duties at the Gen. Hosp., Rangoon, on the 26th Dec. 1900, and assumed ch. of plague inspn. duties, Rangoon.

Hosp. Asst. Kishori Mohan Majumdar, on transfer to Monywa, Lower Chindwin dist., relinquished ch. at the Gen. Hosp., Rangoon, on the 22nd Jan. 1901.

Hosp. Asst. A. Rungasawmy Iyer, on the abolition of the Outpost Hosp., Pale, Lower Chindwin dist., relinquished ch. on the 2nd Jan. 1901, and assumed ch. at the Outpost Hosp., Yinnabin, Lower Chindwin dist., on the 2nd Jan. 1901.

Hosp. Asst. A. Rungasawmy Iyer relinquished ch. at the Outpost Hosp., Yinnabin, Lower Chindwin dist., on the 3rd Jan. 1901 and assumed ch. at the Police Hosp. Monywa, Lower Chindwin dist., on the 4th Jan. 1901.

Hosp. Asst. A. Rungasawmy Iyer assumed ch. of addnl. duties at the Civil Dispy., Yinnabin, Lower Chindwin dist., on the 2nd Jan. 1901.

Hosp. Asst. Hari Chand, on proceeding on six months' leave on med. certificate, relinquished ch. at the Police Hosp., Monywa, Lower Chindwin dist., on the 15th Jan. 1901.

Hosp. Asst. Maung Maung assumed ch. of addnl. duties at the Lock-up, Taunggyi, Southern Shan States, on the 1st Feb. 1901.

Hosp. Asst. K. Govindan, on transfer to Myitkyina, relinquished ch. of his duties with the Mandalay-Kunlon Ry., at Maymyo, on the 25th Jan. 1901.

DOMESTIC OCCURRENCES.

[The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.]

BIRTHS.

MITTEW.—On the 3rd February, 1901, at Tanglin, the wife of Capt. R. K. Mitter, I.M.S., of a daughter.

ELLIS.—At the Waverly Hotel, Naini Tal, on the 24th February, the wife of Lieutenant-Colonel P. M. Ellis, B.A.M.C., of a son.

MARRIAGE.

DREDGE—RICKETTS.—On the 5th February, at St. Mark's Church, Bangalore, by the Rev. W. Barry, Chaplain, James Allen Dredge, Captain, I.M.S., eldest son of James Dredge, Esq., Melrose, Glastonbury, Somerset, to Lillian Didett, youngest daughter of L. L. Ricketts, Esq., late Inspector-General of Police and Forests, Mysore.

ORIGINAL ARTICLES.

THE TEACHING OF OBSTETRICS.

By J. WHITRIDGE WILLIAMS, M.D.,

*Professor of Obstetrics, Johns Hopkins University,
Baltimore.*

THE ideal method of teaching obstetrics would be to divide one's students into two groups, according as they expect to practice that branch of medicine in their future professional work, or as they study it merely as a part of their general training.

To the former an extended course could be given and many subjects considered in detail which are of but little interest to the average student, and facilities could be afforded for a large amount of practical work. While, on the other hand, an elementary course could be given to the second group, in which only the general outlines of the subject would be taught, together with a minimum amount of hospital work. For it appears to me that it is a great waste of energy for a student, who expects to devote himself strictly to internal medicine or to one of the purely scientific branches, to be obliged to devote practically as much time to the study of obstetrics or surgery, for example, as to the subject in which he is particularly interested.

Unfortunately these ideals, desirable as they may be, cannot be attained until the methods of medical education are entirely revolutionized and a system inaugurated in which the individual student is permitted to elect, to some extent at least, certain branches of medicine to which he desires to pay particular attention. So that at present one must be content to instruct all students in practically the same way, no matter what their individual preferences may be, and limit one's aspirations to making one's course as profitable and practical as possible.

For the past two years I have attempted to differentiate my students to a slight extent by affording increased clinical facilities to those who desire them during the summer months. I do this at the end of the third year by ascertaining which students are particularly interested in obstetrics, and then allow 12 of them, who have stood best in their class, to have the run of the wards for three weeks each. In this way each of the 12 students is enabled to see 20 or 30 women delivered, instead of 8 or 10, as the rest of the class. This plan has proved very satisfactory, as it solves the problem to a slight extent, and also affords a method of rewarding those who have done conscientious work.

Obstetrical instruction should be given in the third and fourth year of the medical course, and should consist of—I. Lectures. II. Recitation. III. Manikin work. IV. Laboratory work. V. Demonstrations. VI. Ward classes. VII. Delivery of patients in the lying-in ward. VIII. Delivery of patients in the out-patient department. IX. Clinical conferences or clinics; and X. Examinations. The theoretical and laboratory work should be given in the third, and the practical work in the fourth year.

In considering the details of the course, I cannot do better than by practically repeating what I wrote two years ago for the Committee on Course of Study of the Association of American Medical Colleges.

LECTURES.

At present many teachers favor abandoning didactic lectures in favor of recitations and clinical conferences, but I believe that they still serve a useful purpose, but that their utility depends to a great extent upon the person giving them. If the teacher simply bases his lectures upon some standard text-book, I believe that he will best subserve the interests of his students by abandoning them, and allotting a certain number of pages or chapters of the text-book for recitation at each meeting of the class, which he will supplement by demonstrations of various kinds and free-hand drawings upon the black-board.

If, however, he has higher aspirations, and is able to avail himself of the recent English, French, and German literature, I believe that the didactic lectures will continue to play an important part in obstetric instruction, and will enable the student to obtain a rounded idea of the theory of obstetrics, four or five years in advance of the doctrines laid down in the latest edition of his text-book.

The lectures should be accompanied by as many demonstrations as possible, and the teacher should rely less upon carefully prepared diagrams and drawings, than upon plentiful free-hand drawings upon the black-board. The student may admire the former, but the latter he can reproduce in his note-book.

II. RECITATIONS.

A recitation hour should follow every third lecture, and the student questioned not only upon the work immediately preceding the recitation, but upon the work so far as it has been covered, thus necessitating a constant review of the entire subject.

The students should be encouraged to ask questions freely, and the recitations should be conducted as informally as possible; but at the same time a record should be kept of the work done, which should be considered in estimating the final standing of the student.

The recitation is almost as important for the teacher as for the student, as it enables him to emphasize and elaborate important points and discuss them with the students, and frequently demonstrates how imperfectly he expressed himself in his lectures. The recitations should, therefore, be conducted by the teacher himself, and not be delegated to one of his assistants.

III. MANIKIN WORK.

Exercises upon the manikin should form an integral part of the obstetrical course; but their scope should depend to a great extent upon the amount of material which is available for clinical instruction. If there is a large lying-in hospital in connection with the medical school, it will be unnecessary to attempt to teach the technique of abdominal palpation, vaginal touch and internal pelvimetry upon the manikin, as it can be taught very much more satisfactorily upon the living woman.

But if the clinical material is limited in amount, we consider it advisable that the students be taught the rudiments of palpation, touch and pelvimetry upon the manikin, so that they will know exactly what they are to do when they examine the patients in the wards, whereby clinical material is economised, and the patients saved considerable annoyance. For this purpose the BUDIN-PINARD manikin is to be recommended.

The main object of the manikin work is to teach the various operative procedures, and each student should be obliged to perform all possible operations upon the manikin, at least once during the session.

The manner in which the work should be conducted must vary according to the size of the class. If it does not exceed 50 members, I believe it best to attempt to instruct the entire class together. This can readily be accomplished by employing three or four manikins, one to every 12 students, and having the professor at one and an assistant at each of the others. In this way, three or four men can be operating at the same time.

At the beginning of the hour, the professor should give an outline of the operation, its mode of performance, indications, etc., and then call upon the students to perform it under his supervision. While this is being done, it is well to quiz the class, and thus make the meeting serve a double purpose. Such meetings should last about one and a half hours, during which at least 12 men can operate upon each manikin.

If the class exceeds 50 in number, it will be necessary to divide it into sections. We believe that the professor should always take part in the manikin instruction; and if it becomes necessary to divide the class, he should alternate between the sections.

IV. LABORATORY WORKS.

I consider it imperative that laboratory work should be included in the obstetrical course, as it is impossible for the student to grasp the subject intelligently unless he be more or less intimately acquainted with the minute structure of the organs of generation, and with the lesions associated with the various diseases, which may complicate the pregnant and puerperal condition.

Of course many of these subjects are studied during the first and second years in the courses upon histology and pathology; but owing to the immense field which must be covered in each of these branches, it is impossible to more than touch upon salient points, which are soon forgotten. It is therefore necessary that this field should be gone over again more in detail, and with special reference to the practical side of obstetrics, and this can only be done by one who is particularly interested in this branch of medicine.

This work should be delegated to a special assistant, whose duty it should be to prepare the material for the class, and with the aid of the others, to demonstrate it to them. While this work is going on, the class should meet twice a week for one and a half or two hours. The sections should be given to the students at one meeting, when they must stain, mount, and study them. At the next meeting they should be described by the instructor, who should then go around the class and ascertain that

the necessary points have been made out by each student. It is not advisable to give more than four or five specimens in any one week.

This work should be begun at the commencement of the year, and the normal anatomy of the genitalia and the development of the placenta thoroughly studied. When this is accomplished, the same hours should be devoted to manikin work, and after its completion, the pathology of obstetrics should be taken up. In this way, two meetings a week of one and a half to two hours each may be occupied profitably throughout the year.

If the class exceeds 40 or 50 in number, it will be necessary to divide it into sections of convenient size.

This work, of course, does not necessarily require special laboratory accommodations, as it may be done in the histologic, pathologic, or clinical laboratories, as may be most convenient.

In the following list are mentioned the specimens which may be profitably studied in this manner:—

1. Labia majora and minora.
2. Vaginal mucosa.
3. Longitudinal section of cervix, showing transition from cervical to vaginal epithelium.
4. Transverse section of cervical canal, showing its arborescent structure.
5. Endometrium of young girl.
6. Endometrium of adult.
7. Endometrium of old woman.
8. Pregnant uterus showing increase in size of muscle cells.
9. Involution uterus showing decrease in size of muscle cells and degeneration of vessels.
10. Menstruating uterus.
11. Uterine end of fallopian tube.
12. Central part of fallopian tube.
13. Lateral end of fallopian tube.
14. Round ligament.
15. Ovarian ligament.
16. Infantile ovary.
17. Girl's ovary.
18. Adult's ovary.
19. Senile ovary.
20. Corpus luteum, fresh.
21. Corpus luteum, eight to ten days old.
22. Corpus luteum, two to four weeks old.
23. Corpus luteum of pregnancy.
24. Ovary showing corpora fibrosa.
25. Ovary showing atrophic follicles.
26. Corpus luteum cyst.
27. Decidua, four to six weeks.
28. Decidua, four months.
29. Decidua, reflexa (from abortion).
30. Early chorion, to show double layer of epithelium.
31. Placenta, three months.
32. Placenta, four months, if possible in connection with the uterine wall.
33. Normal placenta at term.
34. Normal placenta at term injected.
35. Uterine wall and fetal membranes outside of placental site.

36. Young umbilical cord, fetal end to show stalk of umbilical vesicle.
37. Umbilical cord at term.
38. Inflammation of decidua.
39. Early placental infarct.
40. Developed placental infarct.
41. Hemorrhagic placental infarct.
42. Normal fetal epiphysis.
43. Syphilitic fetal epiphysis.
44. Syphilitic placenta, fresh, tease out chorionic villi. Compare with normal.
45. Syphilitic placenta, hardened.
46. Hydatidiform mole.
47. Tubal pregnancy, to show decidual and placental formation.
48. Rachitic bone.
49. Osteomalacic bone.
50. Eclamptic kidney.
51. Eclamptic liver.
52. Eclamptic lung.
53. Puerperal infection, showing streptococci limited to decidua.
54. Puerperal infection, showing streptococci in the uterine wall.
55. Puerperal infection, showing streptococci in the broad ligament.
56. Puerperal infection, showing non-involvement of the fallopian tube.
57. Puerperal infection, due to streptococci and putrefactive organisms.
58. Puerperal infection, due to putrefactive organisms alone.

It is apparent that any one who has carefully studied these sections will have a far better and more lasting conception of obstetrics than one who has not.

In addition to the normal anatomy, he will have precise and accurate information upon the ordinary diseases of the placenta, and will be able to diagnose fetal syphilis by the examination of the placenta and the fetal bones.

He will learn, for example, that the hydatidiform mole is not merely a myxoma of the chorionic villi, but that it presents marked changes in its epithelium, which places it in close relationship with the deciduoma malignum or syncytial carcinoma. He will also learn the true nature of rachitis and osteomalacia, and thus more readily understand the genesis of certain varieties of deformed pelvis. By studying the tissues from a case of eclampsia, he will learn that it is a disease not merely of renal origin, but that it is accompanied by lesions in the liver and other organs, which place it in a totally different light. The examination of sections from the various varieties of puerperal infection will afford most important indications for treatment, and teach the futility of curing the uterus in cases of streptococcal infection, and the marked benefit to be derived from the same operation in those forms due to infection with putrefactive and other organisms.

These and many other benefits will accrue from the study of obstetrics in this manner, and we feel that its

importance cannot be urged too strongly upon the teachers of obstetrics.

V. DEMONSTRATIONS.

Demonstrations should also play an important part in obstetric teaching. They should serve partly for the illustration of lectures and frequently should be given independently of them.

Every teacher should exert himself to obtain as many objects as possible which are suitable for demonstration. Many can only be collected gradually, such as frozen sections of pregnant and parturient women, as well as of the fetus and young children of various ages for demonstrating the fetal and infantile pelvis and the relations of the generative organs, series of ova at various periods of development, placental diseases and abnormalities, and many other anatomic and pathologic specimens.

Among the various aids for teaching which can be bought at any time, we may mention: TRAMMOND's three specimens of dissections of the female perineum and pelvic floor, which greatly facilitate the demonstration of this difficult subject; TARNIER's bronze pelvis, manufactured by COLLIN of Paris; EDGAR's aluminum pelvis and blackboard, manufactured by REYNOLDS of New York; EDGAR's models of the pregnant uterus at the several months of pregnancy, also manufactured by REYNOLDS. These models are of great value, in that they enable us to give the student an accurate conception of the exact size of the uterus at each month of pregnancy. EDGAR's casts illustrating the immediate repair of the lacerated perineum are also very valuable, while his leather uterus is a useful adjunct to the manikin, and enables us to teach the student how to pack the uterus with gauze, to check hemorrhage, and to sew up the lacerated cervix for the same purpose.

One of the greatest aids in teaching, especially in this country, where certain forms of contracted pelvis are rarely observed, is the series of 24 models of the various forms of deformed pelvis, prepared by TRAMMOND of Paris. All of them are modeled exactly after celebrated examples of pelvic deformity in the various museums of Europe. An appliance, which is invaluable for demonstrating the genesis of the various forms of deformed pelvis, is the pelvis in "composition molle," manufactured by TRAMMOND, which can be given any shape by the hands.

This list might be extended almost indefinitely, but we have referred only to such models and appliances as we consider essential.

Any one interested in this line of work is referred to the interesting article of Dr. J. C. EDGAR, in the November and December numbers of the *New York Medical Journal* for 1896, which contains many valuable suggestions.

VI. WARD CLASSES.

For teaching the technique of examining pregnant women, the class should be divided into small groups, whose size must depend upon the amount of clinical material available. Each student should be carefully drilled in the principles and practice of asepsis, taught to diagnose the position and presentation of the fetus

by abdominal palpation and vaginal touch, impressed with the necessity of measuring the pelvis, both externally and internally, in every case, etc. They should also be required to take the histories of patients in the ward, to make the necessary urinary examinations, and to accompany the professor or the resident obstetrician at the daily visit.

They should also be required to examine the puerperal women just before they are discharged from the hospital, so as to become acquainted with the condition of the genitalia in the latter part of the puerperal period.

Each student should be required to examine at least ten pregnant women, not including the cases seen during labour, before being allowed to come up for the final examination in obstetrics.

VII. DELIVERY OF PATIENTS IN THE LYING-IN WARD.

A small number of students, preferably two, but certainly not more than four, should be called to the ward to see every case of confinement. They should be required to examine the patient, both internally and externally, once during the first, and again during the second stage of labor. In uncomplicated cases one of the group should deliver the woman himself, under the guidance of a competent assistant.

A much larger number of students may be called to operative cases as on-lookers. Each student should be required to see at least five cases delivered in the lying-in ward; for it is only there that he can learn the ideal method of conducting a labor case. A service of 150 cases yearly will be sufficient for a class of 100 students, provided four students were called to each case.

VIII. DELIVERY OF PATIENTS IN THE OUT-PATIENT DEPARTMENT.

An obstetric dispensary should be organized in connection with every medical school, and poor women delivered at their own homes by students under the personal supervision of an assistant, who should be accompanied by a trained nurse if possible.

The custom of sending two students alone to a labor case cannot be deprecated too strongly; for they are almost certain to fall into slipshod methods and fail to carry out the more or less rigorous technique which they have learned in the lying-in ward. But when they are sent to these cases under the charge of a competent assistant, who is prepared to demonstrate the case and to see that the rules of asepsis are strictly followed, we believe that the out-patient obstetric service will be quite as useful in training students as the lying-in ward, and perhaps more so, in that it teaches them to conduct a labor aseptically under all the disadvantages which are encountered in the homes of the poor, quite as well as in the ward with all its conveniences, and thus they are fitted directly for private practice.

The student should be required to visit the patients during the puerperium, say for the first five days and again on the seventh and tenth days, and should be provided with a fairly full printed history sheet in which he should be required to outline the more important facts concerning the case, which should be given to the assistant in charge after the last puerperal visit.

It should be understood that the instructor regards the return of the history sheet as an important matter, and that the manner in which it is filled out plays an important part in determining the final standing of the student. I consider that two cases carefully observed in this manner are quite as valuable to the student as ten cases seen in the usual way without supervision. Each student should be required to attend at least five out-patient cases; and a service of 250 cases a year would be sufficient to furnish cases for a class of 100 students, if two students conducted each case.

In large cities a considerable part of the out-patient obstetric material is lost for the purposes of clinical instruction by the time consumed in getting the student to the case, especially when he lives a considerable distance from the hospital. To obviate this difficulty, one or more rooms should be provided by the department, according to the size of the service, in which two or more students should be kept on call at night, until they have seen their quota of cases.

IX. CLINICAL CONFERENCES.

During the fourth year there should be a weekly meeting of the class, in which most of the teaching should be done by the students themselves. Here interesting cases which have been observed by the students are discussed. A student who has lately seen an interesting case should be informed a day or so in advance that he is expected to report upon it. When the class meets, he should read a concise history of the case, and then perform upon the manikin the operation which may have been required. The case is then discussed by the instructor, and the class questioned concerning more or less cognate cases.

At another meeting, a dead-born child and its placenta may be exhibited. Two students may be called upon to perform an autopsy upon the child to ascertain the cause of its death; to a third student the placenta may be given, with instructions to tease out some villi, examine them under the microscope, and ascertain if they present syphilitic lesions. This will consume about half an hour. Then the diagnoses are called for, and the history read by the student who observed the case, and it is attempted to bring the clinical history into accord with the anatomic findings, and *vice versa*.

At another meeting, several ova of various ages may be given to as many students, who should carefully examine them and then report what stages of development they represent, and their reasons therefor.

Another very practical manner of spending the hour is to take three deformed pelvis and give each one, with a pelvimeter and a piece of paper to two students. Allow 15 minutes for measuring the pelvis, and then call upon one student in each group for the diagnosis, his reasons for making it, and the measurements upon which it is based. And ask the other how he would diagnose a similar pelvis in the living woman, and what procedure he would adopt to deliver her, etc.

Of course this kind of work may be amplified to almost any extent, and is only limited by the amount of time and material at the disposal of the instructor.

X. EXAMINATIONS.

I do not believe that the standing of a student should be based solely upon the mark obtained in a written examination, but consider that it should also depend upon the character of his class work and the general impression which he makes upon the instructor; and that each of these factors should count equally in estimating his value.

At the end of the third year the student's standing should be estimated from three sources—written examination, recitations, and general class work. The value of the first two is readily estimated, while that of the general class work is of a more personal character, and therefore cannot be determined so accurately. It is based less upon the actual performance of the student than upon the general impression which one gains of him. Thus many a student who can pass a good examination and answer fairly well at recitations, impresses one as an indifferent or poor man by the manner in which he answers and asks questions, and by the way in which he appears to take hold of the subject; while, on the other hand, another student may pass a poor examination, but still show by his class work that he is really an excellent man.

In other words, I advocate basing a part of the total mark upon one's estimate of the personal equation of each student. In very large classes this, of course, is out of the question, and even in small classes one's estimate is not always correct. But any mistake in this respect can usually be equalised or corrected by marking the examination papers without knowing by whom they are written.

In the fourth year the standing should likewise be estimated from three sources—recitations, clinical work, and a practical oral examination at the end of the year.

In estimating the value of the clinical work, special stress should be laid upon the manner in which the history-sheets are filled out and upon the general behaviour of the student. The final examination should be conducted at the bedside or with the manikin, and an attempt made to test the practical knowledge of the student. At the same time questions should be asked of such a character as to give some idea of his powers of reasoning, instead of how well he can memorize a text-book.

Examinations of this character consume considerable time and cannot be well applied to large classes unless conducted by several examiners. But where they can be carried out, I am confident that they afford the most satisfactory means at our disposal of ascertaining what a student is worth.

HYSTERICAL PYREXIA.

By DR. G. KOBLER.

Case I.—A man, aged 21, had a fit which began with general muscular twitchings, and ended with opisthotonus, consciousness being partially lost. The respiration ceased completely for 30 to 45 seconds. The temperature rose to 107.6° , but the pulse remained 72. Similar attacks occurred regularly every day at almost the same time, and lasted 3 to 10 minutes. During the attack

the man moaned and cried out, and before and after there was oesophageal spasm, which prevented swallowing. In the intervals there was constant vomiting of food. Alcohol invariably produced an attack. Enemata of distilled water and mucilage had the same sedative effect as when they contained chloral hydrate. It was proposed, in the hearing of the patient, to place him in an ice-cold bath whenever an attack occurred. Only two very mild attacks followed this threat, and from the eighth day no further attacks or pyrexia occurred. For a time an uncertain gait remained, such as results from cerebellar tumour, but recovery was soon complete.

Case II. A boy, aged 11, of good mental abilities, had intestinal catarrh, which soon yielded to treatment. Though perfectly well all day, at the stroke of 6 every evening he gave a single barking cry and complained of severe pain in the iliac fossa, which, however, was not tender. During the attack, which lasted for 3 or 4 hours, there was motor aphasia, though some barking sounds were produced. The patient understood every word spoken near him, and if a joke were made, concealed his amusement with difficulty. The attack ceased as suddenly as it began; the boy would then demand food and soon fall asleep. At the beginning of an attack the temperature rose abruptly and soon reached 103.6° or even 105.8° . The diagnosis lay between (1) malaria with nervous symptoms, (2) purulent appendicitis, and (3) hysterical pyrexia. The first seemed excluded by the absence of rigors, sweating, and splenic enlargement; the second by the absence of tenderness and intra-abdominal swelling. The boy was isolated in a home and threatened with an operation and the battery if there were any further attacks. The attacks, together with the pyrexia, disappeared promptly and did not return.

WORMSER and BING (*Monch Med. Week.*, Oct. 2, p. 1373, and Oct. 9, p. 1417).—A barmaid, aged 24, belonging to a highly neurotic family, developed hysterical signs at puberty. The sensory abnormalities were anaesthesia, analgesia, hyperaesthesia, megrim, diplopia, contraction of the visual field, and achromatopsia. The motor disturbances were astasia-abasia (*Review*, Vol. II, p. 695), tremors and convulsions with contractions of certain groups of muscles. The patient was erotic and of a typically hysterical disposition. She had acquired gonorrhoea, which was followed by such abdominal pain that the left ovary and tube were removed, and the retroverted uterus was ventrified. Later, total vaginal hysterectomy and right oöphorectomy were performed. At the first operation the only abnormalities were a retroverted uterus, and fixation of the left tube and ovary by adhesions; at the second the right ovary was enlarged, and the tube thickened and tortuous. There were no abscesses. Eight weeks after the operation, at the time when, but for the oöphorectomy, the meneses should have appeared, the patient had a rigor with pains in the loins. The axillary temperature rose to 101.8° and the pulse to 120; later the temperature reached 104.7° . Ten hours later there were partial unconsciousness, cyanosis, contractions of various muscles, and the hands were in the position of tetany—a condition which the writer names "hysterical *petit mal*." Slight pyrexia continued for 36 hours. Every organic source of pyrexia could be excluded; the stamps of the broad ligaments were not infiltrated, and there was no albuminuria.

A number of exact observations show that there is a hysterical pyrexia which is not factitious. That pyrexia may have a central origin is shown by its occurrence after cerebral traumatism. RICHTER has produced it experimentally by injury of the corpora striata. According to CUZIN, ordinary toxic fever depends on stimulation of the thermogenic centres in the base, while hysterical pyrexia is due to paralysis of the inhibitory centres in the cortex. If this is so, it is analogous to other hysterical manifestations, which depend on an absence of cortical control over the lower centres.

A MIRROR OF PRACTICE.

TREPHINING OF THE SKULL FOR FRACTURE.

By M. N. OHREDAK, L.M.S., RAI BAHADUR,
Civil Surgeon, Barabanki.

(Reported by Assistant Surgeon E. MILLICANS, M.B.)

KALI DIN, a Hindu male, aged 35 years, resident of Tiambe, district Barabanki, was brought into the Sudder Hospital by the Barabanki Police on the 26th of January 1901, at about 12 noon, quite senseless, with more or less stertorous breathing. The history, as far as gathered from the people who accompanied him, was as follows:—

History.—According to the statement of his relatives, on the morning of Friday, the 25th January 1901, some eight persons rushed into the house of KALI DIN and began beating him with blows and kicks. His (KALI DIN's) relatives found him lying on the ground quite senseless. Since then, until the time of his admission into the Sudder Hospital, Barabanki, he has been in this comatose state.

Condition on Admission.—Patient altogether unconscious, no amount of shouting had any impression on him whatever. Breathing laboured and stertorous. Pulse slow and laboured. Right side of the body colder than the left side. Conjunctival reflex with right side absent. Pupils on either side equal. On careful examination it was found that the patient was paralysed on the right side. The lower incisor teeth were found loose. Deglutition impaired. Urine is voided involuntarily. At times he moves his left leg, but the rest of the body is like a log of wood. The head of, left radius dislocated forward, but this was said to be an old dislocation. There is a swelling on the left side of the scalp about 2½ inches square above the left ear. There are no external wounds, and no cup-shaped depression as is usually found in depressed fracture.

Diagnosis.—Compression of the left side of brain either from effused blood or depressed fracture.

Treatment.—It was decided to adopt conservative treatment and watch the progress of the symptoms. It consisted of administration of calomel, rest, shaving of head and enemata. In the way of nourishment, milk was given in small quantities, which was swallowed with great difficulty. Nutrient enemata of eggs and milk were also given. There being no change in the symptoms for the better by about 12 o'clock next day, but, on the contrary, the pulse getting rapid and weak, it was decided to trephine the skull and remove the cause of pressure if possible.

Operation.—The patient was therefore put on the table and the left side of the head having been well cleaned first with soap and water and then with turpentine and carbolic lotion, a semi-circular incision was made above the left ear over a spot which corresponded with the junction of the frontal bone with the anterior-inferior angle of the left parietal. This was the spot in which there was a swelling as mentioned above. No chloroform was necessary. The flap was reflected downwards, and it was noticed that the meninges were considerably ecchymosed. The bone being exposed, a linear frac-

ture was noticed running through the left limb of the coronal suture. To ascertain the extent of the separation, an incision was made along the coronal suture upward, and it was found that the whole of the left limb of the coronal suture was opened, and a finger-nail could be introduced into this gap. The crown of the trephine was then applied on the anterior-inferior angle of the left parietal bone just behind the seat of fracture. On removing the circular piece of bone out by the trephine, a dark blood clot was seen pulsating, and on gentle examination it proved to be an extensive one, situated between the dura mater and the skull. With the spoon end of the director, and partly with the finger, this clot was removed piecemeal and a big space was left between these two structures. The weight of the clot removed was approximately an ounce. The cavity was then flushed with (1 in 5000) perchloride lotion, the edges of the wound brought together by silkworm guts, and a piece of muslin was left in at the depending part of the wound to act as a drainage tube. During and after the operation no fresh blood was noticed to flow from inside the trephine hole. Before the patient left the table, calomel, gr. x, with a little ghee was administered to him with much difficulty. It was observed that after the removal of the blood clot the patient, who was altogether silent when put on the table, moaned a little.

The patient was then put to bed. A nutrient enema was given, which he retained. After the operation the pulse rate increased, beating 136 per minute, and the respiration was 48 per minute. Temperature 99° F. The movements of the left leg became more frequent.
